An Address

ON

MODERN METHODS OF DIAGNOSIS AND TREATMENT OF

SYPHILIS OF THE NERVOUS SYSTEM.

Delivered to the Wimbledon Medical Society, at the Nelson Hospital, Merton, on Nov. 10th, 1922,

BY SIR FREDERICK W. MOTT, K.B.E., M.D., F.R.C.P. LOND., LL.D. EDIN., F.R.S.

INTERSTITIAL AND PARENCHYMATOUS (PARASYPHILITIC) FORMS.

To understand the diagnosis and treatment of a disease it is necessary to have some knowledge of the pathology in order to understand how drugs act.

There are two forms of syphilis of the nervous system, the interstitial and the parenchymatous (parasyphilitic). We now know that both forms are due to the active pullulation of a specific organism, the *Spirochæta pallida*. There is some evidence in favour of there being two forms of spirochætal organisms, one the dermatropic, which seeks the external surface of the body, and the other, the neurotropic, which seeks the central nervous system. Anti-syphilitic treatment is successful in the dermatropic form, and either unsuccessful or not nearly so successful in the neurotropic. The neurotropic includes those late forms of syphilis of the nervous system which Fournier termed parasyphilitic. Before the discovery of *S. pallida* in the brain of general paralytics, by Noguchi, it was thought that general paralysis and tabes were the result of abiotrophic processes caused by the toxins of the syphilitic virus.

I have been long struck by the infrequency with which paretic or tabetic patients have suffered with marked skin lesions. In fact, there is evidence to show that if a patient has had a good florid rash he would in all probability not subsequently develop general paralysis.

There is, moreover, epidemiological evidence in support of the existence of two forms. Von Düring was sent from Germany to a province in Asia Minor to investigate venereal disease, which had become very prevalent in a population which furnished the Sultan with some of his best troops. Cases of general paralysis and locomotor ataxy were not found. Again, Colonel Lambkin reported that syphilis was very prevalent among the negroes of Central Africa, especially among the Christian negro population. He likewise observed that tabes and general paralysis were rare. It therefore seems that a recent infection of a race does not lead to these late forms. It is possible in civilised countries, as Neisser suggests, that the organism has become attenuated by the widespread use of mercury, and has therefore acquired a habit of getting into a situation safe from the effects of drugs. Instances are on record of a number of men infected by the same mistress who subsequently developed general paralysis or tabes, and also of cases of conjugal parenchymatous syphilis. I have seen a number of instances of conjugal parenchymatous syphilis. I show the photograph of a man who suffered with tabo-paralysis, and of his wife who was in the same asylum with general paralysis. This may, however, be coincidence. Probably the most striking example supporting this theory of a neurotropic form of spirochæte has been afforded by Brosius, who relates that seven glass-blowers suffered with chancre of the lip, and out of five who ten years later came under observation four suffered with either tabes or general paralysis.

Förster and Tomaschewski removed during life small portions of brain from general paralytics, and found spirochætes in an emulsion of this material. They were unable to inoculate monkeys with this material which contained living spirochætes—a fact which shows these spirochætes, although morphologically indistinguishable from those found in a condyloma, are, nevertheless, not specifically identical. The reaction of the tissues, however, to the toxins of these organisms is the same.

SPREAD OF THE SYPHILITIC VIRUS BY THE LYMPHATICS.

Syphilis spreads from the seat of primary infection along the lymphatics and excites inflammation, characterised by lymphocyte, plasma cell, and connective-tissue cell proliferation in the tissues. The tendency is to fibrosis, but, owing to arterial occlusion, necrobiosis may occur in a syphiloma. The spirochæte gains access to the central nervous system by the lymphatics in the walls of the blood-vessels going to the brain or spinal cord, and along the lymphatics of the spinal and cranial nerves. Now, these lymphatics, which lie in the walls of the vessels and nerves within the cranio-spinal cavity, form part of the general lymphatic system of the whole body. Consequently, when the generalisation of the infection of the lymphatic system occurs colonisation of the spirochæte occurs in various parts of the body; the lymphatics in the cerebro-spinal meninges may then be infected and give rise to symptoms. In quite a large number of the cases of secondary syphilis the cerebro-spinal fluid gives a positive Bordet-Wassermann reaction, together with lymphocytes and protein, showing that spirochætes or their toxins have entered the central nervous system.

If syphilitic organisms get into the sheaths of the cerebro-spinal vessels then they may have a neurotropic action, and find their way into the parenchyma; here they may remain latent for a number of years before undergoing active pullulation and symptoms of disease, but they will, nevertheless, during this latent period give rise to a Bordet-Wassermann reaction (W.R.) of the cerebro-spinal fluid which, in many cases, even prolonged treatment cannot remove. It seems probable that these cases of a fluid remaining positive after prolonged treatment are cases which subsequently (on an average ten years after the primary infection) develop tabes and general paralysis. This can be explained by the fact that the organism is no longer in the general lymphatic system, but in the closed system of the cerebro-spinal fluid which irrigates the nervous tissue. The various anti-syphilitic drugs — e.g., arsenobenzol compounds, mercury, &c.—cannot pass through the choroid plexus which secretes the cerebro-spinal fluid, and therefore they do not, when administered, come into contact with the organisms. Similarly these drugs have not proved successful in sleeping sickness, when the *Trypanosoma gambiense* is found in the cerebro-spinal fluid.

The interstitial form of the disease is very amenable to treatment because the organisms are in the general lymphatic system, and if the spirochæticidal drugs are employed before the inflammatory reaction of the tissues have caused neuronic degeneration a cure can be effected; indeed, no serious organic disease of the nervous system yields such strikingly satisfactory results as that due to syphilis—provided prompt and efficient treatment is adopted. Most practitioners have now disabused their minds of the long prevailing idea that organic disease of the nervous system is usually a tertiary phenomenon of syphilis. Fournier long ago showed that the greatest number of cases occur in the first two years and diminish with each succeeding year. I have myself seen a case with symptoms and signs of meningitis while the sore was yet unhealed.

SIMULTANEOUS OR SUCCESSIVE AFFECTION OF TISSUES IN BRAIN AND SPINAL CORD.

There are many forms of syphilitic disease of the nervous system. As a rule both the brain and spinal cord are simultaneously affected, and the disease is regarded as spinal or cerebral syphilis according to the predominance of spinal or cerebral symptoms. This is pathologically explicable, for it depends upon the mode of extension along the lymphatics. The reason why the base of the brain is probably so frequently affected is explicable by the spread of infection along the lymphatics of the vertebral arteries. Cerebral and spinal symptoms frequently occur simultaneously. There is hardly any organic disease of the nervous system which may not be simulated by syphilitic disease, but it must be remembered that many functional diseases may occur in syphilitic subjects. Neurasthenia with syphilophobia, on account of venereal disease propaganda, is frequently met with at the present time.

Cerebral Syphilis.

Syphilis may produce an endarteritis, but not until occlusion of diseased vessels by thrombosis do obtrusive signs and symptoms occur, such as various forms of motor and sensory paralysis. Premonitory symptoms, such as headache, lapses of consciousness, and symptoms which might be considered neurasthenic occur. Endarteritis may, however, be associated with signs and symptoms of meningitis, and various forms of paralysis, especially of the eye muscles and the optic nerve, commissure or tracts may be affected and visual defects and blindness result; other cranial nerves may also suffer. Headache, worse at night, with any of the above signs and absence of pyrexia should always make one suspect syphilis as a cause. Again, gummatous tumours may occur in severe cases, and then general signs and symptoms of tumour, associated with meningeal or vascular symptoms. Solitary syphiloma may occur and give rise to all the signs and symptoms of increased intracranial pressure, and it is well to point out that its not yielding to antisyphilitic treatment does not preclude its diagnosis. The reason appears to be that in the central nervous system drugs have not the same powers of absorption as elsewhere in the body; especially is this the case when sufficient time has elapsed for the formation of a dense fibrous capsule around the gummatous mass.

Spinal Syphilis.

Syphilitic meningomyelitis is the most frequent cause of paraplegia in young male adults, and root pains and dysæsthesia over the skin segments corresponding to the roots affected are the earliest warning symptoms; the superficial and deep reflexes may be affected. Now if we look at the sections of the spinal cord of a man who suffered with meningomyelitis, you will see that the inflammatory reaction has spread along the septa which carry the lymphatics and blood-vessels, and if this is allowed to proceed from delay in treatment, there will result a focal transverse myelitis. The fibres of the long tracts of the spinal cord which carry voluntary impulses from the brain to move the muscles of the lower extremities will be cut through, and a descending degeneration of the upper segment of the motor path will ensue. Regeneration of these long tracts which convey impulses from and to the brain cannot occur, and a spastic paraplegia is the result. [These pathological conditions of the nervous system were demonstrated by the lantern.]

Diagnosis by Laboratory Methods.

If syphilis is suspected, or even if it is not, in many cases of nervous disease a W.R. of the blood should be obtained; if this is negative, syphilis can, as a rule, be excluded as the cause. If it is positive, it does not necessarily follow that the disease is syphilitic, for a large number of people may give a positive W.R. of the blood and yet not be suffering from syphilis of the nervous system.

In numerous cases where there are nervous symptoms indicative of organic disease of the nervous system, the pathological nature of which has not been determined, lumbar puncture should be performed and the fluid examined. A positive W.R. makes it certain that the spirochæte is in the nervous system. If there is at the same time a marked protein reaction and a large number of lymphocytes and plasma cells, the case is one of active syphilis of the nervous system and requires immediate treatment. The cells and the protein may disappear, and in rare cases even the W.R. also, but in the great majority of cases, even when all symptoms have ceased, the W.R. may remain, so that the diminution and disappearance of the cell and protein reactions may serve as a useful means of determining the success of the treatment. I may remark that in general paralysis the fluid practically always gives these three reactions; it also gives a colloidal gold reaction, which it is said helps to distinguish the disease from interstitial syphilis of the nervous system. A considerable percentage of cases of tabes with obvious clinical symptoms may not give a positive W.R. of the fluid; this, however, should not be a deterrent to antisyphilitic treatment. It is possible that in these cases the toxin, but not the spirochæte, has, at one time or another, gained access to the closed system of the central nervous system.

Drug Treatment of Syphilis of the Nervous System.

General Principles of Treatment.—The diagnosis of the nature of the syphilitic lesion having been made, it is necessary to decide upon the mode of treatment. It is better not to have a fixed scheme, but to be guided by general principles dependent upon the age, health, sex, and weight of the patient, together with the character and intensity of the syphilitic affection and history of previous treatment for syphilis or other diseases. I have already emphasised the importance of an examination of the cerebro-spinal fluid both in diagnosis of preclinical affections of the nervous system as well as in affording an indication of progress and success of treatment. The modern treatment by salvarsan requires a thorough clinical examination. The older a patient is, the greater should be the care in the dosage, method, and frequency of administrations. Disease of the lungs, of the heart, or the arteries, and especially of the kidneys, calls for special attention and care. It must be borne in mind that in a fair proportion of cases of disease of the nervous system a combination of diseases of these organs occurs. Arterio-sclerosis and other degenerative conditions should make one especially cautious in persons of advanced age; those whose constitutions are broken down by chronic alcoholism or disease also require great care. The urine should always be carefully examined. A trace of albumin with no casts, or with only a few hyaline casts, may exist in syphilitic patients, or the presence of albumin may indicate an idiosyncrasy. Seeing that in fatal cases following salvarsan injection the kidneys have been found to contain the most arsenic of all the organs of the body, it follows that even a trace of albumin should make one cautious in the administration of either mercury or salvarsan. The urine should be tested twice a week during treatment, and any indication of albumin present prior to treatment, and the appearance of granular casts, should be a danger-signal either to beginning or continuing arsenobenzol treatment. Probably small doses of neosalvarsan are less dangerous than mercury injections in syphilitic albuminuria.

Selection of Mode of Treatment.—In the matter of selection of mode of treatment it is very necessary to discriminate between active inflammatory processes due to active spirochætal pullulation causing a generalised gummatous meningitis or localised gummatous tumours, and necrotic softening due to thrombosis of vessels caused by a pre-existing endarteritis in which there is no evidence of active development of the specific organisms. I have in mind cases which gave a negative Bordet-Wassermann reaction, and yet by treatment were relieved of symptoms. Of course, the two conditions may occur simultaneously at all periods of time following infection, although the combined conditions on the one hand are especially liable to ensue in untreated or inefficiently treated cases occurring in the first few years after infection; the necrotic softening, on the other hand, occurs more often in the later tertiary stages where there may be no clinical evidence of active spirochætosis. The clinical symptoms, pointing to irritation phenomena, should be recognised before any arterial thrombosis and necrotic softening occur, or, if the signs and symptoms point to necrotic softening with paralytic phenomena, we should make certain whether there is any active inflammatory process occurring simultaneously.

Before the introduction of salvarsan great success was obtained in such cases by immediate and energetic mercurial treatment, either by injections or inunctions, and it is well not to forget that mercury is still of the greatest value in treatment.

Having decided that the patient is fit for a particular course of treatment, it is necessary to decide how and by what channel the treatment is to be administered. The introduction of the arsenobenzol treatment does not imply that it is necessary to discard old and well-recognised methods of treatment such as mercurial inunction and injection, or the use of iodide of potassium. In cerebro-spinal syphilis I have seen the most satisfactory results obtained by such methods of treatment before the introduction of salvarsan. In making a choice the physician will be influenced in his decision by various circumstances—e.g., the chronicity of the symptoms, the result of examination of the blood and cerebro-spinal fluid, the advisability of consulting the patient's interests and feelings—particularly in the matter of prescribing mercurial inunctions for a married man—and also upon the likelihood of the patient carrying out satisfactorily such a mode of treatment.

Modern Intensive Mode of Treatment.—The treatment which is usually adopted for syphilis of the nervous system is as follows: A dose of 0·15 to 0·3 g. of neosalvarsan is given either intramuscularly or intravenously to test the individual's tolerance to the drug. This is repeated in a few days' time, and, provided no signs of intolerance are shown, a week later a full dose of 0·6 to 0·9 g. is given and repeated each week for from six to eight weeks. The weekly dosage may be regulated by the condition of the patient, and the evidence of tolerance or intolerance shown by the reactive phenomena. Plaut recommends an initial ten days' course of mercurial inunction, and a series of grey oil injections at three-day intervals (five injections of 0·2 to 0·5 g.). The urine should be tested for albumin each week, and other symptoms of intolerance of the drug or evidence of chronic intoxication should be carefully looked out for. An examination of the cerebro-spinal fluid and blood should be made at the end of the course of treatment, and the four reactions compared with those obtained prior to the beginning of treatment.

Some authorities are content with the employment of arsenobenzol alone; others give weekly mercurial intramuscular injections of 0·03 to 0·05 c.cm. of mercury, grey oil, or calomel cream, or a course of mercurial inunction consisting of 30 to 40 rubbings of unguentum cinereum, one drachm (4 g.) may be employed. Mercury in the form of Hutchinson's pill, 1 gr. (60 mg.) of grey powder and 1 gr. (60 mg.) of pulv. ipecac. comp. three times a day, may be used in some cases. Between the courses of treatment eight weeks are usually allowed to intervene. Iodide of potassium in 10 to 15 gr. doses or even more three times a day may be given in the interval according to tolerance of the drug, combined with ½ to 1 dr. doses of tincture of cinchona.

At the International Congress of Neurologists, held in Paris in 1920, Sicard pointed out that in certain cases grave symptoms and occasionally fatal results may arise in the course of, or consecutive to, the employment of arsenobenzol compounds. These are directly or indirectly due to its administration. They are as follows: (1) Idiosyncrasy—i.e., individual susceptibility to arsenic which may occur in a syphilitic or non-syphilitic subject directly, or some minutes after the intravenous injection, or even one or two hours after. The patient is seized with anguish, general malaise, and vasomotor disturbances, which especially affect the face. These last from some seconds to a few minutes. Sometimes the attack is accompanied by a general trembling, nausea, and rise of temperature; this is the nitritoid crisis of Milian. Another sign of predisposition to arsenical intolerance is the appearance of erythematous rashes after the first dose. (2) The neuro-recidive or Herxheimer reaction. He pointed out that mercury does not produce this reaction, and that its administration prior to the administration of salvarsan prevents the appearance of this reaction. (3) Anaphylaxis. The reactions of an anaphylactic character are often serious. They may be fatal, and they are characterised by convulsive movements, pulmonary œdema, and coma. Anaphylactic shock occasionally occurs on the next day, or the day after the second or third weekly injection.

Sicard states that in 200 to 300 cases of neural syphilis, treated exclusively by small repeated doses of neosalvarsan, he has not had a single case of anaphylactic shock. The preparations he uses are novarsenobenzol, galyl, and sulfarsenol, in doses of from 0·15 to 0·2 g. They can be used intravenously, or by dissolving in an oily medium or aqueous glucose; they can be used subcutaneously or intramuscularly. In this way he obtains a total dosage of 8 g. of the medicament. He states that only once has he noticed an abscess result, and that intramuscular injection is nearly painless. Following Sicard, I have employed intramuscular injections of novarsenobenzol in aqueous glucose in similar small repeated doses, and this treatment has been very successful and painless. This "driblet" method has also been advocated by Colonel Harrison, who states as follows: "The subcutaneous injection has the further advantage that it can be given without reference to a meal." Sicard claims that in chronic syphilitic diseases of the nervous system the results are superior to those obtained by weekly intravenous injection, and the Bordet-Wassermann reaction of the blood and cerebro-spinal fluid shows a better result by repeated small doses every two days for a period of two months than by the weekly injection. He does not believe that small doses produce an arseno-resistance, as experiments seems to indicate. Harrison states that sulfarsenol has the great merit of causing little pain when given subcutaneously or intramuscularly. He also states that he has found that silver salvarsan appears to be twice as strong as sulfarsenol, and he has found it very useful in tabes and other syphilitic diseases of the nervous system. He also relates the history of a case of general paresis. While admitting that remissions occur spontaneously in this disease, he considers that although this case is incomplete it has "proceeded far enough to show that colossal doses of silver salvarsan do affect adversely the deeply-buried spironemes."

POSSIBLE TOXIC INCIDENCE OF THE INTENSIVE CURE.

A slow progressive intoxication by the arsenic, whether given intravenously, weekly, or by repeated small doses every other day, may be manifested by the following signs: (1) Erythematous rashes are symptoms of the terminal phase of the treatment and indicate an interruption of further injections for at least eight to ten weeks; they also point to caution being exercised in further administration. Some authorities have noticed that certain tubes of novarsenobenzol have appeared to be more productive of an erythematous dermatitis than others. (2) An early indication of the toxic action of the arsenic on the peripheral nerves is the disappearance of the Achilles tendon-jerk, although there is no paresis or necessarily any subjective sensory disturbances. (3) Jaundice, which usually clears up in from three to four weeks. In pushing the treatment these signs of toxic effects should be carefully looked for.

550571

The careful practitioner, knowing of these early complications and late intoxications, will prudently apply the knowledge of their causation to their prevention and thus avoid risks as far as possible. Harrison, in a recent valuable article on the Modern Treatment of Syphilis,[1] states: "Jaundice and dermatitis have certain features in common. Both are apt to be fatal, and both may appear long after a course of injections has been given." Considering the immense number of cases which have been treated successfully by the intensive method, we should not be deterred from using this valuable intensive mode of treatment of neurosyphilis by the fact of occasional accidents.

INTRATHECAL TREATMENT.

Injection of Serum Salvarsanised In Vivo.—In 1911, working independently, Swift and Ellis, Marinesco, Fisher, and George Robertson introduced the method of treatment of syphilis of the nervous system by intrathecal injection of serum salvarsanised in vivo. The general consensus of opinion is that spinal intrathecal injections of salvarsanised serum or hypotonic solution of neosalvarsan are still on trial, and it is not yet proved that they possess advantages over the intravenous or intramuscular methods of treatment. Another method is to give intravenous or intramuscular injections of arsenobenzol or silver salvarsan, followed by lumbar puncture and withdrawal of cerebro-spinal fluid. The intracranial injections in the treatment of general paralysis have been for the most part given up. I have made autopsies in a number of cases so treated, and have found active spirochætosis.

We have yet to learn whether salvarsan treatment will reduce the number of cases of tabes and general paralysis; there is a feeling on the part of a good many neurologists that the modern treatment by arsenobenzol compound presents no very great advantage in the treatment of neurosyphilis over that obtained by the systematic treatment by mercurial inunction and intramuscular injections of mercury combined with iodide of potassium. This, however, may be due to the fact that when the new treatment was introduced many patients thought that a few intravenous injections of salvarsan would be sufficient to complete a cure, and Harrison, from a long experience, has uttered a note of warning that "unless a patient is willing to persevere until he has received a substantial amount of the arsenical remedy, it is better to withhold the latter—this applies especially to tabes."

It is well to note that even after prolonged and intensive treatment the blood may give a positive Bordet-Wassermann reaction, but if the patient's fluid shows a positive reaction as well as the blood a constant menace remains, although the patient may exhibit no clinical symptoms. The positive reaction of the blood is not nearly of so great importance, for I have found a large number of people of all ages giving a positive reaction of the blood, and yet exhibiting no signs indicative of syphilitic disease, or at any rate of disease which would bring them to the doctor for treatment. It is well to mention this fact, for the general public are aware of the significance of this blood reaction, and I have seen many cases of syphilophobia in consequence of an exaggerated view of its importance.

---

[1] Brit. Med. Jour., July 1st, 1922.

THE COMPLETE WORKS OF PASTEUR.—Messrs. Masson et Cie, Paris, are issuing a complete edition of the works of Pasteur in seven volumes, of which two have already appeared. It appears that Pasteur's works have never been collected. They are at present scattered in reports to academies, in reviews, and scientific journals; only the studies on brewing and silkworm disease have been put under one cover. Dr. P. Vallery-Radot has arranged the selection, adding a number of notes and hitherto unpublished information. The two volumes which have already appeared are entitled "Dissymétrie moléculaire" and "Fermentations et générations dites spontanées."

An Address

ON THE

TREATMENT OF SYPHILIS,

WITH SPECIAL RELATION TO ITS LATER MANIFESTATIONS.

Delivered before the Harrogate Medical Society on Dec. 7th, 1922,

BY L. W. HARRISON, D.S.O., M.B., CH.B. GLASG.,
DIRECTOR OF V.D. DEPARTMENT, ST. THOMAS'S HOSPITAL.

MAY I first say something on the prevention of the later manifestations of syphilis? Prevention is particularly important because the best results of treatment of late syphilis leave a greater or less degree of crippling or deformity. We may put out the fire but we can do nothing towards rebuilding the house, and Nature can do little. Although only a comparatively small proportion of syphilitic subjects may suffer from late effects, these may be so tragic that we must consider their possibility in every case, and apply to that case such measures of prevention as we can command.

First I would urge a thorough initial treatment. I fear that the tendency in this country to be content with sufficient treatment to convert the blood reaction to negative and then to wait and see, or else to continue treatment only with mercury, may leave us with a high proportion of cases in which recurrence occurs in the central nervous system. In the early days of "606" we witnessed a large increase in the number of cases of early syphilis of the central nervous system, as shown by paralysis of various cranial nerves, notably the facial and auditory. Considerable research has been carried out with a view to discovering why the brunt of syphilitic recurrences following purely arsenobenzol treatment fell so often on the central nervous system; and this, as I interpret it, seems to be the explanation. The unchecked syphilitic process calls forth an immunity response on the part of the tissues. There is natural evidence of this in the long periods of latency which generally follow the secondary stage, and in the fact that the late recurrence falls so very often only on a damaged or overworked part of the body; where, in fact, the tissues have temporarily lost their supremacy over the parasites. There is, I think, experimental evidence of immunity not only in the fact that, so long as the disease exists, the patient cannot be re-inoculated, but also in the recent work of Eberson,[1] who found that if the serum of a syphilitic subject of some years' standing is mixed with syphilitic virus, and the mixture injected into a rabbit's testicle, infection does not occur, though the same virus infects when injected alone. Interference with the syphilitic process by means of agents which destroy *Spironema pallidum* stops the production of the immune substance in proportion to its effect on the virus. Brown and Pearce[2] found in animals that if an arsenobenzol compound was given which interfered with the development of the initial lesion but did not destroy the parasites completely, generalised syphilis was more certain to follow. Further, the stage in the development of the initial lesion at which the interference took place seemed to determine the sites of recurrence. Thus, after very early interference the recurrence very often occurred in bones. If the initial lesion was allowed to progress a little further, bones escaped, but skin and mucous membranes were affected, and by allowing still further development of the initial lesion, time was given for the bones, skin, and mucous membranes to soak up, if I may put it so, enough immune substance to make them resistant, but interference at that point would often leave the eyes unprotected, and recurrences occurred there. In other words, the experiments tended to show that, as a result of a local lesion, the remaining tissues of the body gradually acquired a resistance, but that this acquisition was not even or simultaneous, bones taking the first supply of immune substance, then skin, and mucous membranes. These experiments and the other facts I have cited seem to go far towards explaining neuro-recurrences after an insufficient arsenobenzol treatment. The syphilitic process is stopped in the periphery and with it the production of immune substances; the remedy does not reach the central nervous system in sufficient concentration to kill the parasites there, and the central nervous system is left at their mercy without the help it would otherwise have derived from immune substances elaborated in the periphery. It might be argued from this that it would be better not to interfere but to leave things to Nature, relying on a sufficient production of antibody. Although, however, the natural resistance of very many patients seems to be sufficient to carry them to old age in fair, or even good, health, we know, on the other hand, that it is often insufficient and that treatment on right lines gives better results. The point to remember in considering what are right lines is that treatment stops the stimulus to antibody production and that it must be at least as penetrating, as far-reaching, and as effective as would have been the antibodies if we had allowed them to form. Otherwise our patient falls between two stools.

Incidence of Syphilis at the Present Day.

A few months ago it was suggested to me that we should soon know whether arsenobenzol treatment reduced the incidence of general paresis and tabes. I thought not, because even yet the idea is not dead that a few doses of arsenobenzol are sufficient to cure a case of syphilis, so that the arsenobenzol treatment has hardly had a chance of showing what it can do towards preventing late recurrences. In fact, for the reasons I have given, I fear that general paresis and tabes may increase for a time in consequence of the small amount of treatment administered to large numbers of patients since the introduction of salvarsan. Had these been on mercury or even left untreated the disease would have continued to simmer in the periphery and the central nervous system would have received some protection from the immune substances formed in the periphery.

At present, however, there is no sign of any increase in general paresis, judging by figures supplied by the Registrar-General, from which the following table has been constructed :—

Deaths per Annum from General Paresis, 1906 to 1921.

Average per annum, 1906 to 1918 :—

		Maximum.	Minimum.
Males ..	1777	1940 in 1917	1713 in 1908
Females ..	457	568 in 1906	341 in 1918
Total ..	2234		

Proportion of females to males : 1 to 3·9.

Year.	1919.	1920.	1921.
Males	1336	1270	1254
Females	272	234	283
Totals	1608	1504	1537
Proportion of females to males..	1 to 4·9	1 to 5·4	1 to 4·4

I am not able to account for the great decrease in deaths from G.P.I. from 1919 to 1921, and I have shown the figures only to combat an idea which seems to prevail in some quarters that this manifestation of syphilis is on the increase even now. I do not think the decrease is connected with treatment, since, in the case of females at any rate, the great majority of cases of syphilis infected five or more years ago must have been treated just as inadequately as was the custom 20 or 30 years previously. The present-day figures do not seem to me an index of what to expect in the future, and I still fear that those who are content with merely getting rid of peripheral symptoms by means of arsenobenzol injections may be laying up trouble in store for the future in the form of severe recurrences in the central nervous system. About 30 per cent. of our cases start treatment with pathological spinal fluid; we know that it is easier to convert the blood to negative than the fluid, and for this reason alone it seems to me that we ought to go on with treatment far beyond the stage when the blood first becomes negative. If it were practicable to do so, I would not dismiss any case from treatment unless and until the spinal fluid had been negative for some months, and, whenever it could be arranged, I would take at least one specimen of spinal fluid at the end of the 15 or 18 months of arsenobenzol and mercurial treatment, which I prescribe *as a minimum* for secondary cases. I believe that, if this were universal, we should have little to fear from late recurrences.

Importance of Positive Blood Reaction.

As another measure of prevention of late syphilitic recurrences I advocate strongly the persistent treatment of the case with a positive blood reaction, but no other signs discernible by ordinary examination. As you know, opinions differ on this point; some say that treatment is a hopeless business, as the reaction will never become permanently negative, and that in any case a positive at this stage means nothing. I hold strongly that a positive blood reaction indicates active syphilis. If it did not, I cannot understand why treatment should affect the reaction, as can be shown by carrying out a quantitative test of its strength from time to time. It is mainly out of the ranks of the positively reacting persons that we get sudden deaths from syphilitic myocarditis, tabetics, general paretics, and so forth, and if we are going to prevent these tragic consequences of syphilis we ought to keep the patient under treatment as long as he shows any signs of being uncured, even though it may be for many years. If a patient with an infection of long standing and with a positive blood reaction had negative spinal fluid, we might perhaps remit a little from the programme, but even a negative fluid is not a guarantee that the central nervous system is free; besides this, we are still left with the danger of recurrences in the cardiovascular system and the viscera. The treatment I usually prescribe for these cases of clinically latent syphilis with positive blood reaction is an initial course of seven to ten injections of "914," or similar product, totalling 4·5 to 6·3 g., with 7 to 10 gr. of mercury by injection, and this is followed by a series of courses of five to six injections of arsenobenzol and mercury at intervals lengthening from 2 to 3, 4, and 6 months as the treatment proceeds. In these cases also I think it useful to supplement the arsenobenzol and mercury with iodide, employed in short courses of two or three weeks after each course of injections.

Treatment of Some Late Manifestations of Syphilis.

May I now speak of the treatment of some late manifestations of syphilis?

Myocarditis.—In this condition I have had some most encouraging results from deep subcutaneous injections of sulfarsenol (0·3 to 0·48 g.), combined with mercury and iodide by mouth, in the form of yellow iodide of mercury. The total amount of sulfarsenol in each course is about 6·0 g. The mercurial treatment commences with three tabloids of gr. $\frac{1}{8}$ a day, and works up to eight or even 12 tabloids a day, or until signs of intolerance develop. The intervals between courses are about six weeks at first and increase to about three months. In the intervals I give some preparation containing more iodine than is present in the yellow iodide, such as potassium iodide, rhiodine, alival, or iodicin, for about three weeks prior to each course. The results can be excellent, but naturally the patient must be in the best possible circumstances to carry out the general régime appropriate to persons with enfeebled cardiac musculature.

I have in mind a case of syphilitic myocarditis sent to me by Dr. F. W. Price, which seemed at first hopeless from the point of view of restoration to work. I had to exercise great care over the dosage at first, or symptoms were aggravated, but gradually the process was brought under control after about 10 months' treatment, and the patient is now again at work as a surgeon.

Aneurysm.—Here I think the ruling circumstance as regards dosage is the possible association of myocarditis and coronary endarteritis. In such cases I treat on the same lines as myocarditis, giving small doses of arsenobenzol twice weekly. Otherwise cases of aneurysm seem able to stand quite large doses of arsenobenzol, and to one case in which there was also general paresis I repeatedly gave huge doses of silver-salvarsan (up to 1·0 g.) without ill-effect. I would always treat such cases with anti-syphilitic remedies, even though the artery cannot be restored to its normal condition, because stoppage of the active syphilitic process seems the only way which offers any hope of staying the progressive weakening of the vessel walls.

Hepatic Syphilis.—This manifestation calls for caution with arsenobenzol in view of its toxic effect on liver cells. In such cases I would recommend always to keep the patient well fed with carbohydrates, on the principle that liver cells which are full of glycogen do not take up such poisons as chloroform and arsenobenzol. The suggestion was made to me by Prof. Hugh MacLean at St. Thomas's Hospital, and its application seems to have had the effect of reducing the incidence of jaundice there very considerably.

Visceral Syphilis.—I need only detain you over visceral syphilis to remind you that more and more cases simulating gastric carcinoma, gastric ulcer, and chronic gastritis are being proved by the effects of anti-syphilitic treatment to be syphilitic in origin, and it seems rational that, in such cases, a blood examination should always be made with a view to a trial of anti-syphilitic treatment if the result should be positive. It is, of course, hardly necessary to mention that more than one tabetic patient's abdomen has been opened as a result of the belief caused by a gastric crisis that something tragic had happened to the stomach or duodenum. I have touched only lightly on the subject of visceral syphilis because I should otherwise have little time left for syphilis of the central nervous system, which may occur early or in the later stages.

Syphilis of the Supporting Structures of the Central Nervous System.—In this condition, manifested by gumma, thrombosis of cerebral and spinal blood-vessels, meningitis and meningo-myelitis, the outlook is generally good, provided that treatment commences promptly. Too often irreparable damage has been done before the case is recognised as a syphilitic recurrence, and the treatment fails to restore function completely. I have found this particularly in the case of neuro-recurrences. For example, a patient has been treated some time previously with arsenobenzol and then left; paralysis of facial and auditory nerves has followed, and the cause of the paralysis has been unrecognised, or perhaps even attributed to the arsenobenzol; the result is that treatment is not resumed, all life is crushed out of the affected nerve by the syphilitic process, and the patient is left with permanent facial paralysis and nerve-deafness on one side. I would suggest in all cases of syphilis of the supporting structures of the central nervous system a fairly low dosage at first, in bi- or even tri-weekly injections, as the internal coats of arteries are practically always thickened, and a Herxheimer reaction causing a little further thickening may stop the flow of blood through a very important vessel. After a few weeks' treatment on the lines of cautious individual dosage, one can usually proceed with doses such as are considered safe for ordinary cases. Courses of treatment should total at least 6 g. of "914" before an interval of any length is allowed. As soon as the course is finished I start giving iodide of potassium, or some organic preparation of iodine, pushing it for about three weeks. As in all other cases, I recommend strongly that treatment be prolonged in courses of injections with intervals extending gradually from six weeks to three months, until long past the stage when the blood and cerebro-spinal fluid have been rendered negative.

The correct treatment of syphilis of the parenchyma of the central nervous system has, as you know, aroused great discussion, particularly in America, where the protagonists and the opponents of the Swift-Ellis and the Ogilvie methods of intrathecal injections wage fierce battles. Both these forms of treatment depend on the principle that, since arsenobenzol introduced into the systemic circulation does not reach the parenchyma of the central nervous system, it is better to put it into the subarachnoid space, where it will mix with the cerebro-spinal fluid and so be brought into contact with *S. pallidum* buried in the parenchyma of the central nervous system. Excellent results are claimed for this form of treatment, and I have myself seen cases benefit by it who were not progressing well on the ordinary intravenous or intramuscular treatment, but, like many others, I am uncertain as to the rationale of it. At least three factors are concerned in intrathecal therapy. The intravenous injection, the lumbar puncture, and the introduction of the salvarsanised serum. Intravenous medication usually acts well. Lumbar puncture alone has also an effect on tabes, as I have seen two cases in which the mere withdrawal of a few c.cm. of cerebro-spinal fluid resulted in recovery of power by a previously paralysed bladder. Both these factors have to be reckoned with in the usual intrathecal therapy. What about the effect of the third? Is it because the medicament introduced into the spinal canal acts more potently on the spirochætes in the parenchyma, or is it because of some non-specific action, whether it be from assisting the passage of the drug from the systemic circulation to the lymph of the central nervous system, or in some other way? It seems to me at least open to doubt whether the cerebro-spinal fluid is the lymph of the central nervous system and does therefore come into contact under natural conditions with the parenchyma. I admit that substances introduced into the cerebro-spinal fluid can be forced back to the neighbourhood of the pyramidal cells, but I feel some doubt about its occurring under natural conditions. The cells of the nervous system are highly organised, and the liberality of their blood-supply indicates a large requirement in food, while the cerebro-spinal fluid is such thin stuff that one wonders how it could possibly contain the required nourishment. Some work by J. Wynn[3] seems to indicate that even when arsenobenzol introduced into the spinal canal is brought into close contact with the brain parenchyma the results are indifferent. Thus intravenous injection of 15 per cent. salt solution results in the cerebro-spinal fluid being drained back into the systemic circulation, as shown by Weed and McKibben[4] and by Foley and Putnam,[5] and iron salts introduced into the spinal canal of animals prior to this internal drainage are found later in the vicinity of the pyramidal cells. Wynn gave 200 c.cm. of 15 per cent. saline intravenously to human beings and at the same time introduced salvarsanised serum into the spinal canal. As mentioned, the results in a number of cases were indifferent, and Wynn concluded that intraspinal injections combined with internal spinal drainage was of no therapeutic value. His experiments seem to show that intraspinal therapy is of no value unless combined with antisyphilitic treatment by the systemic route. Further, since in these cases the drug was brought into far closer contact with the parenchyma than occurs under the ordinary conditions of intraspinal treatment, it seems reasonable to suppose that the drug injected into the subarachnoid space does not act by virtue of any spirochæticidal effect.

[5] Ibid., 1920, liii., 464. Referred to by Wynn.

Another form of treatment of parenchymatous nerve syphilis is that introduced by Gilpin and Earley and advocated strongly by Dercum. The principle is to assist penetration of the drug given into the systemic circulation by lowering the intrathecal pressure. The patient receives a full dose of an arsenobenzol preparation, and in the next half hour or so as much fluid as possible is drawn off by lumbar puncture, the idea being to break down the resistance of the cerebral vessels to the transudation of arsenobenzol by exerting a strong pull from the subarachnoid side. I have tried this form of treatment in some cases of G.P.I., and they have done well, but I have also given very large doses of silver-salvarsan at the same time and am not quite sure how much the drainage contributed to the result. Excellent results have, however, been claimed for the method by Hearn[6] working at the London Lock Hospital, and he employed only ordinary doses of arsenobenzol. Regarding the drainage method of treatment in tabes, my experience leads me to recommend some caution. Cases of tabes seem to be much more sensitive than others, not only to excessive individual dosage, but to excessive drainage, as I have seen them made definitely worse by both faults in treatment. I have seen cases of tabes benefit by simple lumbar puncture, removing only a few c.cm. of fluid, but that is different from the removal of 40, 50, or even 80 c.cm. of fluid, as is done in the Gilpin-Earley method. So I try an ordinary lumbar puncture first and see how the patient stands it, just as I always try very small doses of arsenobenzol, and watch pretty carefully before venturing on increases.

Another method of carrying out the Gilpin-Earley principle of spinal drainage has been suggested by Corbus, O'Conor, Lincoln, and Gardner.[7] It is based on the effect of intravenous injection of hypertonic saline which I mentioned earlier in connexion with Wynn's work. The patient receives at, say, 10 A.M. an intravenous injection of 100 c.cm. of 15 per cent. sodium chloride solution. The effect of this is to cause an enormous reduction in the cerebro-spinal fluid, as has been proved on animals. At about 4 P.M., when the tide of cerebro-spinal fluid is well on the turn, so to speak, flowing back to the subarachnoid space, the patient receives a full dose of an arsenobenzol compound, and, after being in bed all day, is allowed to go home at 9 P.M. Corbus and his colleagues found that, after five such treatments at weekly intervals, arsenic could be demonstrated in the cerebro-spinal fluid in 26 out of 28 cases, a higher percentage than has been attained by other means. I have no experience of this form of treatment.

TREATMENT OF TABES.

May I now mention the lines on which I would actually treat a case of tabes? Generally I would reserve intraspinal medication for cases which resisted the ordinary methods. That is, I think, common sense, as all forms of effective treatment make great demands on the patient, and lumbar punctures are not too pleasant an addition. I like best to combine intravenous injections with deep subcutaneous injections. For the intravenous I prefer silver-salvarsan to all others, and for the subcutaneous, sulfarsenol, because it hurts less. Patients vary greatly in their susceptibility to pain after sulfarsenol injections, but generally stand them well, especially if each is preceded with 0·5 c.cm. of 3 per cent. novocaine injected through the same needle. As mentioned, I start with very small doses, and watch to see how the patient tolerates them. For instance, 0·05 g. silver-salvarsan given intravenously is followed in three or four days by 0·12 g. sulfarsenol given subcutaneously. The dose is increased gradually to 0·3 g. silver-salvarsan, and 0·48, 0·54, or even 0·6 g. sulfarsenol until the patient has received about 2·5 g. silver-salvarsan and about 4 to 4·5 g. sulfarsenol. Then the injections are stopped for six to eight weeks while the patient receives, first a course of two or three weeks' iodide, and then yellow iodide of mercury by mouth. Sometimes I have to treat only with silver-salvarsan, and sometimes only with sulfarsenol, because the patient tolerates one of these better than the other. If sulfarsenol is the only arsenobenzol remedy, I give mercury by injection or by mouth at the same time, and I always give iodide at the end of the course. I always tell the patient he must expect to remain under treatment by regular courses of injections with intervals during which he will be taking some form of medicine, for quite two years, and if he is one who thinks that he will leave the decision as to further treatment to the result of the first course, I prefer that he shall go to someone else. I think that, if a patient will comply with the conditions, one can offer much in tabes, even though there may be a fair amount of ataxia. The halo of meningitis often disappears fairly quickly, and a particularly pleasing result of treatment with silver-salvarsan has been the disappearance of lightning pains. As a class I should say that the tabetics attend my department at St. Thomas's Hospital more faithfully than any other, mainly, I think, because of the relief given them in this direction. If a patient does not progress well enough or at all on the lines I have mentioned, I have in reserve for him intraspinal medication or else drainage, either, of course, combined with systemic treatment.

TREATMENT OF GENERAL PARALYSIS OF THE INSANE.

I should like now to say something on the treatment of G.P.I. In a British Medical Association[8] lecture I mentioned a case of G.P.I. which had done extraordinarily well on huge doses of silver-salvarsan combined with drainage. Briefly the details are these. I saw him first in an asylum in July, 1921, and gave him a few injections, after which he refused further treatment. A remission followed, and he was removed home. I resumed treatment about October, 1921, and pushed the doses up to about 0·6 g. silver-salvarsan, giving a total of 3·2 g. by Nov. 26th. Then I became nervous of the dosage and stopped the injections. After about two months' rest it became clear that he was relapsing and going steadily downhill. So I resumed treatment after about three months and gave him over 8 g. silver-salvarsan in ten injections, which finished in April, 1922. Under this treatment the relapse was stopped practically at once, and the improvement at the end of the course was most remarkable. He did not relapse in the next interval, and, commencing on July 2nd, 1922, I gave him a short intensive course of 3 g. silver-salvarsan in four injections and 2·88 g. copper sulfarsenol in six injections up to the beginning of September. I saw him a few weeks ago and he was in excellent condition. He requires no attendance, goes out to lunch and dinner, and no lay person who was ignorant of his history would detect any abnormality. Really, however, he is not mentally the same acute business man he was; he is just such a nice, quiet, pleasant-mannered gentleman as one often meets and classes as by no means a congenital idiot but not likely to set the Thames on fire. What is particularly pleasing is that his cerebro-spinal fluid, which was strongly positive at first, was normal when last examined. Assuming the disease has been arrested in this case, we are left with the irreparable damage it had done when we interfered. I have had some other cases, but have not had such a free hand as regards their treatment as in this case, and the results, though not unsatisfactory, have not been so good. The hope which such a case as this raises is for the patient who is pre-paretic or is in the stage where not much damage has been done. If it could happen that all persons with a history of syphilis had their cerebro-spinal fluid examined at regular intervals, or even if the medical profession had learnt well to have the cerebro-spinal fluid examined whenever a patient showed the least sign of central nerve disease, I think we could save many a household from the misery, the financial loss, and, I may add, the shame which general paresis brings to it.

[7] Jour. Amer. Med. Assn., 1922, lxxviii., 264.

[8] Brit. Med. Jour., 1922, ii., 1.

To summarise my address, I have tried more than anything else to emphasise the importance of thorough treatment in the first instance to prevent the late sequelæ of syphilis, thorough treatment when the only evidence of syphilis is in positive bacteriological findings, and thorough treatment when the patient has been allowed to develop one of those crippling or deforming late manifestations of syphilis which have made it the dreaded disease it is.

TUBERCULOUS AFFECTIONS OF THE TONGUE.

BY R. M. HANDFIELD-JONES, M.S. LOND., F.R.C.S. ENG.,

ASSISTANT DIRECTOR, SURGICAL CLINICAL UNIT, ST. MARY'S HOSPITAL.

IT is now over 100 years since a tuberculous lesion of the tongue was recognised and reported. Portal[1] in 1804 is generally credited with the description of the first case; for, though Morgagni[2] in 1761 mentioned a patient in whom tubercles were found in the tongue, yet this case cannot be accepted as proved owing to the lack of definition of the word tubercle as then used. Portal was followed by Louis[3] in 1825, Reñaud[4] in 1831, Fleming[5] in 1850, Gildmeister[6] in 1851, and Paget[7] in 1858. In every instance the cases described were examples of lingual lesions secondary to pulmonary or laryngeal tuberculosis. In 1872, however, Enteneur[8] published the first primary case, and in 1876 Nedopil[9] followed with four cases which he claimed to be primary, but of these three cannot survive close investigation, and must be classed as secondary. Since then several cases have been published at intervals, so that in 1916 Scott[10] was able to collect 231 cases, including 26 claimed to be primary. From that date till the present time I have been able to find only two cases in the literature (Amorosi[11] and White and Marcy[12]). Just recently Pinel,[13] in his *Thèse de Paris*, reports 21 cases.

I have now to report five cases which have occurred in general surgical hospital practice (St. Mary's Hospital) within the last two years. Two of these patients presented themselves in the same week, and I was led to wonder if lingual tuberculosis is as rare a manifestation as is generally supposed. I have therefore written to 10 London general hospitals and 10 sanatoria asking for details of cases since 1910. This inquiry revealed only 12 cases, and it can justly be stated that at any rate in the environs of London lingual tuberculosis is a rare disease. Moreover, this would appear to be general throughout Europe and America, as Blancard's[14] figures suggest; for (1) in Blancard's own experience in 3935 autopsies on tuberculous subjects only 25 had lingual lesions, or 0·063 per cent.; (2) among 12,369 patients in German sanatoria only one tongue was affected, or 0·00008 per cent. (Hamel)[15]; (3) in the Winyah sanatorium in the United States 19 cases were found in 3000 patients (von Ruck).[16]

My cases presented several features of interest, and in that this subject is treated rather cursorily in the text-books of surgery, I was led not only to inquire into its frequency, but also to review it from the standpoint of the general surgeon. I therefore propose to deal with the subject in detail under various headings.

Ætiology.

(*a*) *Age.*—There appears to be no limit to the age incidence, for of the reported cases the oldest was 80 (Zintsmaster[17]) and the youngest 18 (Nicola[18]). The commonest decades are the fourth and fifth, and probably as many occur after 50 as before 30.

(*b*) *Sex.*—There is a very general agreement that males are more liable to be attacked than females. The ratio is variously given as 4 : 1 (Chrostek[19]), 5 : 1 (Schliferowitsch[20]), 23 : 1 (Delavan[21]), 5 : 1 (Nannini[22]), 3 : 2 in my series, and 5 : 1 in those I have collected from other sources.

(*c*) *Incidence.*—Undoubtedly the tongue is rarely the seat of invasion of the tubercle bacillus, which seems strange when the enormous incidence of tuberculous affections in general is considered. The reasons for this comparative immunity of the tongue are, first, the thickness and resistance of the mucous membrane; secondly, the marked antagonism of striated muscle fibres to bacillary invasion (with one or two exceptions—e.g., gas gangrene); thirdly, the constant flow of mucus and saliva cleanses the tongue; and, lastly, the continual movements of the tongue have the same effect.

(*d*) *Methods of Infection.*—The portals of entry for the tubercle bacillus are: 1. Direct inoculation. Injuries of the tongue may be directly infected and refuse to heal, giving rise to a tuberculous ulcer. Sinabaldi (quoted by Fulle[23]) describes such a case. 2. Inoculation from the sputum. This is by far the commonest method. 3. The blood-stream. 4. The lymph-stream. 5. Spread from neighbouring structures—e.g., the face, lips, tonsil, and naso-pharynx; this explains the occurrence of lupus.

Pathology.

There are no fewer than seven manifestations of tuberculosis in the tongue. Of these the best known is the ulcer, and little attention is paid to the others. These seven lesions are as follows:—

1. In generalised miliary tuberculosis the tongue may be studded with the typical small tubercles characteristic of the disease.

2. The tuberculoma or tuberculous granuloma. In recent years Murphy[24] and Mouisset[25] have each reported a case, and two of my cases are of this variety. Pinel states that only 20 examples occur in the literature. The mucous membrane appears normal in every respect, but beneath it there is formed a small tumour of slow growth, which is painless. It is usually not larger than a cherry-stone, is hard and not definitely circumscribed, and is fixed firmly in the substance of the tongue, the mobility of which is not impaired. It is usually seen projecting from the surface of the dorsum nearer to the edge than the mid-line. Microscopically the mucous membrane is intact and may be somewhat hypertrophied (Figs. 3 and 4). In Fig. 4 there is a very marked formation of "tubercles" lying closely packed together, so that there appears to be a definite tumour in the subepithelial tissues.

3. The cold abscess. This is a rare type, and since 1910 only two examples are recorded by Nannini[22] and Fulle.[23] It arises as a result of caseation occurring in a tuberculoma.

4. The ulcer. The commonest manifestation, which is situated on the side, tip, and dorsum in that order of frequency. In size it begins as a very small ulcer, and rarely attains the area of a florin. Its appearance is so typical that its recognition should always be possible by clinical examination. It is superficial, not deeply penetrating, and is lined by pale-yellow granulations, exuding a yellowish pus. The edges are not undermined and are sinuous in outline—the ulcer being nearly circular—and the walls slope gradually to the floor, which when cleaned of the pus shows the typical weakly pale granulations. There is little or no induration around, until there is an established secondary infection. Around it—and here is the most illuminating feature of all—is a ring of satellite tubercles, which are quite small, and usually need a magnifying glass for their demonstration.

5. The fissure. These may occur as the only lesion in the tongue, or, as more frequently happens, may be present with an ulcer. They are found along the edges rather than on the dorsum, and at first sight they appear as quite insignificant cracks in the surface of the mucous membrane; but if the edges are separated their depth is surprising, and they will

be seen to be lined with the pale greyish granulations exuding a thin slight discharge. No induration will be found around them except in the presence of a secondary infection.

6. The papillomatous or verrucose type. The former is described by Clayton-Greene[26] as an inflammatory hyperplasia of the mucous membrane in the neighbourhood of a fissure giving the appearance of a true papilloma. The latter is described by François Dainville,[27] and is of the same nature.

7. Lupus of the tongue. The tongue is attacked by lupus vulgaris by direct spread either from the skin of the face or from the naso-pharynx. It is quite a well recognised complication occurring in 15 cases in 1000 at the Licht Institute, Copenhagen (Strandberg [30]). In its pathology it differs in no way from lupus elsewhere, being confined to the epithelium. In the tongue it presents a pinkish-grey raised plaque without any inflammatory reactions, and is firm and hard. It may retain its sclerotic characters, and is then known as "glosso-dermatitis tuberculo-fibrosa," or it may break down into the surface ulceration typical of cutaneous lupus, and is termed "glosso-dermatitis tuberculo-ulcerosa" (Duranti[28]).

Symptoms.

It will be readily understood that the symptoms will vary with the pathological type. The tuberculoma and cold abscess will present painless swellings which give rise only to inconvenience or, at the most, discomfort in talking or swallowing. The ulcer, on the other hand, makes its presence most unmistakably felt. It is an exquisitely painful and tender lesion. The discharge is not sufficiently copious to be a source of discomfort, but talking, eating, and drinking are reduced to a minimum on account of the pain. In addition, there is in some cases profuse salivation. The question of the involvement of the lymphatic glands is vexed, and perhaps the balance of opinion is against a resulting adenopathy in the neck. My experience is the reverse, and not only is there no reason why it should not occur, it is, rather, a natural sequence of events.

Diagnosis.

There can be no doubt that these conditions give rise to many difficulties in diagnosis, and the tendency on the part of many observers has been to consider a microscopical examination as essential to a definite opinion. To that view I must take exception, and I should approach the problem from several aspects. In the first place the differential diagnosis of the tuberculoma and the ulcer is quite different and must be discussed separately.

1. *The Tuberculoma.*—The following conditions give rise to localised swellings in the tongue:—Lipoma, fibroma, myoma, neurofibroma, endothelioma, sarcoma, carcinoma, teratoma, gumma, and actinomycosis.

The encapsuled benign neoplasms will differ from the tuberculoma in that they are movable within the substance of the tongue. The malignant ones are harder and more rapidly growing, and will have more surrounding induration. The early gumma and actinomycosis may present the greatest difficulties, for at certain stages their clinical appearances may be very similar. But they both break down more rapidly, the one into the typical gummatous ulcer, and the other into multiple sinuses discharging the sulphur granules.

One other aid to clinical diagnosis exists, and that a most valuable one. In an overwhelming majority of cases there exists a coexistent tuberculosis of the lungs or larynx, even if entirely unsuspected. Attention may here be drawn to two of my cases (Nos. 2 and 4), for in neither of these patients was there anything to draw attention to the possibility of pulmonary tuberculosis, both strongly denied any of the stigmata of tuberculosis, and neither had been off duty for years; yet the clinical examination of the lungs showed definite evidence of lung involvement, which was confirmed by radiology. Therefore a careful examination of the lungs and larynx should invariably be done, and in the great majority the clue to the diagnosis will there be found. I would here lay it down in this connexion that no case can be accepted as a primary infection unless this has been done. Many of the claimed primary cases reported bear very slight investigation; the existence of a true primary case seems to me more than a little doubtful. It would have been easy to claim my two examples of tuberculoma as primary cases, if no examination of the lungs had been carried out. The reason that these patients go undiagnosed or misdiagnosed is that the possibility of the lesion being tuberculous is overlooked.

2. *The Ulcer.*—Lingual ulceration has many causes, but for all practical purposes three need to be differentiated from the tuberculous, viz.: (*a*) traumatic or dental, (*b*) syphilitic, and (*c*) carcinomatous. It is frequently taught that the tuberculous ulcer has the following characteristics—that it occurs at the tip, is multiple, and is seen in the last stages of pulmonary tuberculosis. Nothing could be more fallacious. The ulcer is not often multiple, not infrequently the lung infection is latent, and though it may occur at the tip, it is more often seen on the edges opposite the molar teeth. Once again I would plead for a more accurate observation of the findings, for therein is the diagnosis to be read. I have already described the ulcer, and would draw attention to the satellite tubercles. Perhaps the simplest way of contrasting the physical signs of these four types of ulcer is in a table.

I would once again emphasise the importance of examining the chest in every case.

CONTRASTING PHYSICAL SIGNS OF FOUR TYPES OF ULCER.

—	Tubercle.	Traumatic.	Syphilitic.	Neoplastic.
Depth.	Shallow.	Varied.	Deep.	Deep.
Colour.	Yellow-grey.	Pinkish-yellow.	Grey.	Dirty grey.
Edges.	Sinuous and not undermined.	Indurated.	Ragged and undermined.	Raised and everted.
Sides.	Sloping.	Sloping.	Punched out.	Ragged and sloping.
Floor.	Pale yellow granulations.	Sloughing.	Yellow-grey slough.	Necrotic.
Induration.	Nil.*	Present, not marked.	Present.	Marked.
Pain and tenderness.	Very marked.	Marked.	None.	Slight; sometimes referred pain severe.
Local causes.	Nil.	Dental caries, &c.	None.	Unknown.
Other signs.	Fissures, sentinel tubercles and pulmonary tuberculosis.	Nil.	Leucoplakia.	Nil.

* Present with the onset of secondary infection.

Supplementary Methods of Diagnosis.

In that accurate diagnoses are not always arrived at, however careful the clinical investigation, it is right that subsidiary aids to diagnosis should be made use of. We have the following methods at our disposal:—

(1) Tuberculin tests; and (2) the von Pirquet reaction. (In my opinion these tests are quite valueless, and no reliance should be placed upon them.) (3) The complement-fixation test is at present being tried out, and Punch and Gosse [29] has published an encouraging preliminary report. As yet no expression of opinion as to its efficacy is possible. (4) Examination of a smear of discharge, and debris from the ulcer

may reveal the presence of the tubercle bacillus. (5) Histological examination is conclusive, and as seen in my sections is typical; tuberculous granulation tissue, "epithelioid" cells, and giant cells are always to be seen. It is not easy to demonstrate the bacillus in the tissues, owing to difficulties in staining and decolourising tissue sections. One detail in technique is important in removing pieces of tissue for histological [purposes. When one is dealing with a tuberculoma, the whole tumour must be excised and the gap in the tongue closed by sutures. If only a portion be removed the lesion rapidly breaks down and one is confronted with an ulcer, leaving the patient worse off than before. (6) Inoculations of suspensions of suspected material into guinea-pigs. This is an infallible proof, but it takes some considerable time to carry out.

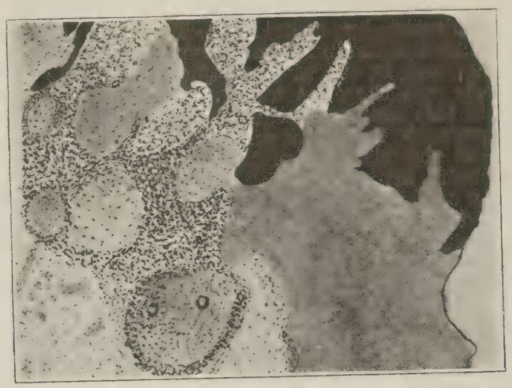

FIG. 1 shows an ulcer with a necrotic base, the mucous membrane at the periphery being hypertrophied. Numerous giant-cell systems are seen surrounded by a small round-cell infiltration. The muscular tissue of the tongue is invaded and is being destroyed. There is considerable formation of collagen fibre. Occ. Zeiss x2, obj. Leitz 1, tube length 150 mm.

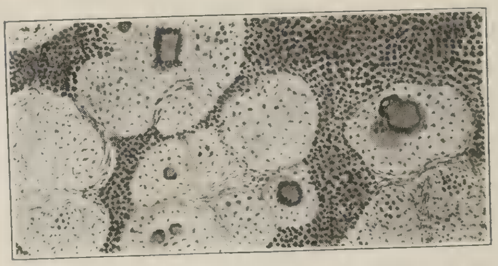

FIG. 2.—Section of lymph node from same case as Fig. 1. Shows a well-marked tuberculous involvement of the node. Numerous giant-cell systems are present, as well as many areas of masses of epithelioid cells without giant cells. Occ. Zeiss x2, obj. Zeiss 26 mm., tube length 160 mm.

Treatment.

Treatment must obviously vary with the type of case. It must be kept in mind that the lesion is secondary, and that therefore nothing is indicated but the destruction of the local condition. The tuberculoma should be completely excised and the gap sutured. This can be done easily by taking a wedge from the tongue, and this equally applies if the diagnosis is in doubt and the excision is for histological purposes. It is found that the incision heals firmly without ulceration. The ulcer is not so easy, for local excision and suture does not give a clean result, the wound breaking down, leaving a larger tuberculous ulcer than before. Local applications are recommended by various authors, such as bipp, lactic acid, chromic acid, &c., but they do little good. The best treatment is the destruction of the ulcer by electro-coagulation by means of the diathermy apparatus. The resulting scar is firm without contraction, there is no pain after the operation, and the wound heals with less tendency to reinfection than any other method. The Pacquelin and galvano-cautery give fair results, but do not approach diathermy.

Lupus.—The treatment of lupus of the mucous membranes in general has been greatly advanced by the work in the Licht Institut, Copenhagen. There these cases are treated by "ionisation reversed," which is carried out by giving the patient large doses of sodium iodide by mouth for three days, and then applying the positive pole to the tongue. In this way the required agent is drawn from the tissues through the diseased area. The results, I understand, are admirable. I would suggest that it would be well worth while trying the effect of the diathermy current here also, for it has already been used for cutaneous lupus with success. In that the tuberculous lesion of the tongue is secondary to pulmonary phthisis, it must be borne in mind that general treatment should be begun at the earliest opportunity.

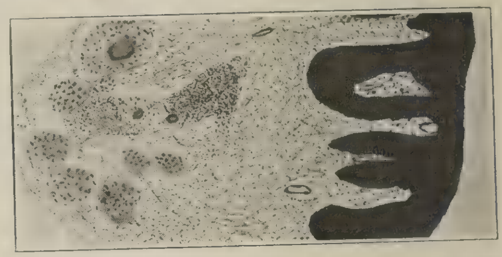

FIG. 3.—Section of tongue showing slight hypertrophy of mucous membrane. In the submucous tissues and invading the muscular tissues of the tongue is a small collection of "tubercles," including three with well-marked giant-cell systems. There is a considerable round-celled infiltration in two definite areas, and throughout the section there is much collagen fibre present. This is typical of a tuberculoma. Occ. Zeiss x2, obj. Zeiss 26 mm., tube length 160 mm.

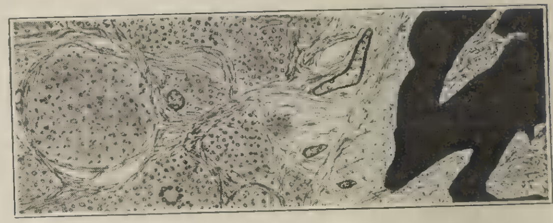

FIG. 4.—Here there is some hypertrophy of mucous membrane. The main bulk of the drawing and, indeed, of the whole section consists of a mass of "tubercles." Large numbers of epithelioid cells are irregularly divided up by collagen fibres, but there are only two giant cells present in the field, and two others in process of formation. The whole section presents exactly the same picture. This is another example of the tuberculoma, but the difference between this and Fig. 3 is most striking. Occ. Zeiss x2, obj. Zeiss 26 mm., tube length 160 mm.

CASE 1.—Male, aged 59. (Service of Mr. W. H. Clayton-Greene.) First seen in October, 1920, complaining of an ulcer on the tongue. Seven weeks previously he had bitten his tongue, and very shortly after a little lump appeared at the same place. This gave him no pain, but had been a source of inconvenience, and smarted somewhat when he smoked. One month later the lump broke down into a very painful open sore. On examination there was found an ulcer about the size of a sixpenny-piece on the left edge of the tongue opposite the first molar tooth, having indurated and everted edges. There was much dental caries, and the glands in the left submaxillary and carotid triangles were markedly involved, and, in addition, there were two palpable glands in the right submaxillary triangle. The condition was confidently diagnosed as carcinoma, the patient was sent to the examination for the M.R.C.S., and the diagnosis went unquestioned by the Board of Examiners. The man, though exhaustively questioned, had no history of any pulmonary affection, and when examined prior to operation the lungs showed no clinical signs of any morbid lesion

On Nov. 3rd half the tongue was removed by Mr. Clayton-Greene, and an extensive dissection was made of the glands of the left side. Eight days afterwards the patient began to cough, and the histological examination, having revealed the error in diagnosis, the sputum was found to be heavily infected with tubercle bacilli. Physical signs of broncho-pneumonia were now present, and on Dec. 6th he died from double tuberculous broncho-pneumonia, the autopsy showing extensive changes in both lungs, and many lesions in the trachea, larynx, and ileo-cæcal region. Fig. 1 shows the histology of the ulcer on the tongue, and Fig. 2 one of the glands.

CASE 2.—Female, aged 42. Seen by me as an out-patient in August, 1921, having noticed a small swelling on the side of the tongue for some weeks previously. It had not been painful, but had annoyed her because she was always conscious of it. She presented a swelling the size of a split pea on the left side of the tongue opposite the second molar tooth. The mucous membrane was intact over it and appeared normal. The lump itself was firm and regular in outline and fixed to the lingual parenchyma. There were several satellite tubercles, and one definitely enlarged gland was palpable in the left submaxillary triangle. She had no history of any pulmonary affections, and insisted that since 1910 she had not been off duty for one single day. Before that date she could remember no illnesses. However, Prof. F. S. Langmead examined the chest and reported "over the right apex in front and in the axilla there is loud breathing and prolonged expiration; behind the same with increased vocal resonance, and fremitus and whispering pectoriloquy." The radiograph showed very clear evidences of invasion of the right apex with cavitation, and Dr. G. Harrison Orton had no doubt as to the tuberculous nature of the infection. The swelling was removed and the gap was sutured. The histology is shown in Fig. 3.

CASE 3.—Male, aged 28. This patient was sent to my out-patients' department from a sanatorium with an ulcer on the edge of his tongue opposite the second molar tooth on the right side. The medical superintendent of the sanatorium had diagnosed a tuberculous ulcer, but the patient desired a second opinion, his father having died of carcinoma of the tongue. There was a small ulcer on the margin of the tongue (diameter ½ in.), very painful and tender, and showed all the characteristics of the tuberculous ulcer, including the satellite tubercles. He was under treatment for pulmonary phthisis at the time. In view of the patient's anxiety a piece was removed for microscopy, and the findings were typical.

CASE 4.—Female, aged 37. This patient was seen in May, 1922, by my colleague, Mr. D. C. L. Fitzwilliams, by whose courtesy I was enabled to see the case. Three months ago she had noticed a small grey swelling on the under surface of the tongue exactly in the mid-line and ½ in. behind the tip. This had not worried her, but two months later she noticed that the swelling was becoming evident on the upper surface in a corresponding position and has been steadily growing since. It now bothers her because of its presence in the mouth. There was nothing in her past history suggestive of any pulmonary affections, but there was a bad family history. A lump was found which spread through the whole thickness of the tongue, ½ in. behind the tip. The mucous membrane was intact; several satellite tubercles were easily seen by the magnifying glass. There was one definitely enlarged gland in the left submaxillary gland. The lump was removed by wedge incision and the gap sutured. Histology is seen in Fig. 4.

CASE 5.—J. N., male, aged 42. This patient was admitted in the terminal stage of pulmonary phthisis, and had an extensive ulceration of the tongue and a foul condition of the mouth generally. The ulcer was larger than usual, but was otherwise typical. Unfortunately no autopsy was possible, so no specimen was available. There were many enlarged glands in the neck.

In conclusion, I would say that the figures have been drawn with the Zeiss camera lucida. It may be recalled that THE LANCET in a recent leading article drew attention to the markedly unsatisfactory nature of micro-photographs and pleaded for actual drawings. I have therefore made the latter, and I have to thank Dr. E. H. Kettle for giving me facilities for work in his laboratory, and for kindly advice with the drawings. I have also to thank Mr. W. H. Clayton-Greene and Mr. D. C. L. Fitzwilliams for permission to publish cases; and to the former my grateful thanks are due for his inspiration and encouragement during the past three and a half years in which I have had the privilege of association with him in some of his surgical work.

(Continued at foot of next column.)

FORMS OF TUBERCULOUS ARTHRITIS AND THEIR TREATMENT.*

BY E. WARD, M.D. CAMB., F.R.C.S. ENG.,
TUBERCULOSIS OFFICER, SOUTH DEVON.

THE best way to introduce the subject is to start from the cases mentioned below and develop the theme as we proceed. By sternly limiting the cases cited, an effort has been made to avoid obscuring the wood by the trees.

I do not wish to be dogmatic, or to speak as an authority, or to claim any finality for what is said. I am only groping in the dark, dissatisfied with the present classification and treatment of tuberculous arthritis, and trying to evolve something better in the light of the clinical material which comes to my notice. I have tried to widen my views on these matters not only by visits to the best-known special institutions for surgical tuberculosis, but also by visiting various general and special hospitals in London and the provinces, and by the observation of new methods, however heterodox and unconventional.

Polyarticular, Suppurative Type.

CASE 1.—Male. Polyarticular tuberculous arthritis of the suppurative type. At the age of 1 year the extremities swelled. Various operations were performed on the hands, feet, and elbows, while some sinuses appeared spontaneously. When he was about 7 all the joints cleared up, and have remained healed, but much deformed since. When 8 and 9 he suffered from pleurisy. When 11 he had tuberculous meningitis, with vomiting and marked head retraction. He was 11 weeks in bed but made a good recovery. When 16 a cough developed, and there was hæmoptysis, which has recurred since, and definite physical signs were found in the chest.

There is now (at 20) much scarring and deformity of the fingers and toes, hands, feet, and elbows. There are also tuberculous scars on the left thigh and buttock, and a nodule in the right globus minor testis.

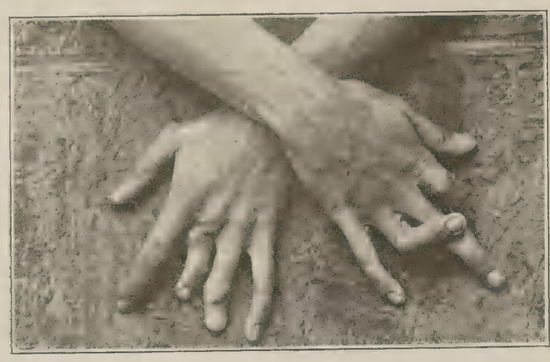
FIG. 1.



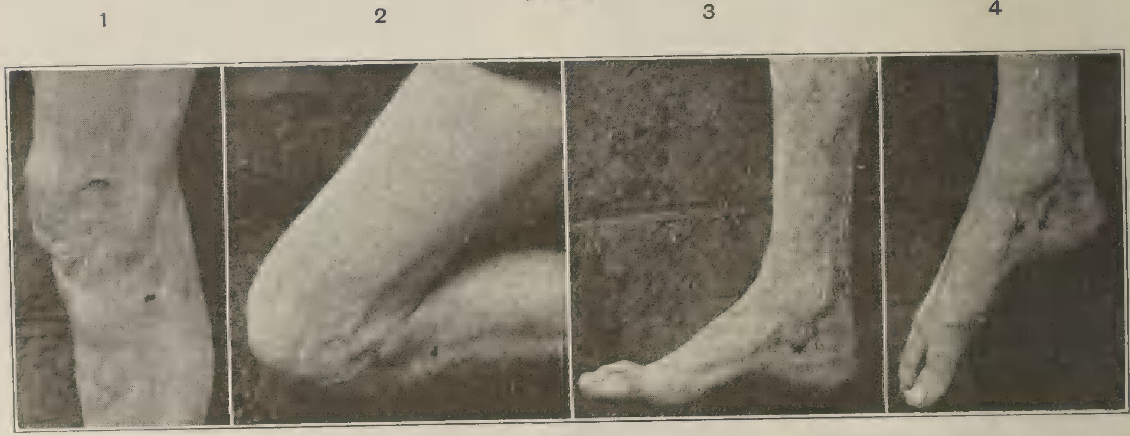
CASE 1.—Results of polyarticular tuberculous arthritis of suppurative type.

The combination of suppuration and high resistance to tuberculosis seen here seems to be usual. A case of tuberculous meningitis that gets well is no longer considered one of the medical wonders of the world.

CASE 2.—Male. Another example of the suppurative type. The left knee swelled when the patient was a boy of 19, and tuberculosis was diagnosed. An abscess formed and was opened two months later. Then the neck and the right ankle swelled and discharged, and abscesses appeared over the left sixth and seventh ribs. At the age of 20 the left ankle swelled, but subsided, and in a few weeks was normal again.

At 21 an abscess appeared in either groin and the patient was admitted to hospital with 22 sinuses, in a condition that appeared hopeless. No splints were applied, and no method of extension was used; he was just fed, and kept clean and cheerful; his disposition was a great help. After hanging fire for some time he began to improve. The sinuses commenced to heal, but contraction of the knees and right ankle occurred; the left knee became flexed to a right angle, riddled with sinuses. The patient was discharged after one and three-quarter years in hospital with five sinuses (right ankle, left knee, and both groins), but able to get about on crutches, and his deformities already improved by his efforts to walk and to straighten the limbs in bed. Sixteen months later all sinuses had healed, the joints appeared functionally normal, and the patient was about to obtain work. The left knee, though it could be flexed and extended almost normally, required more muscular effort than normal for this movement and gave rise to a grating noise audible 10 to 12 yards away.

FIG. 2.



CASE 2.—After four years. (1) Knee extended. (2) Knee flexed to show functional recovery. (3) Ankle dorsiflexed. (4) Ankle extended.

I would like to emphasise the more or less transient swelling of one ankle, as we shall have occasion to return to this shortly. The remarkable functional recovery I attribute to the attempts to straighten the limbs being made while the joints still discharged and the fibrous tissue was still young.

CASE 3.—A married woman, in whom tuberculosis of the left hip, with suppuration, occurred at the age of 29. A year later there was hæmoptysis and spinal caries, and the patient was kept in bed for seven months. At 31 she was confined and three months later hæmoptysis recurred, also the left hand swelled, and was operated upon, healing within three years. At 34 the right hand swelled and was operated upon. Vomiting and gastric trouble next supervened, and for three years the patient was ill in bed. A laparotomy at 38 revealed tuberculosis of the stomach. At 40 there was an attack of pleurisy. At 41 the right arm and hand swelled and discharged. The three inner fingers of the right hand were removed at 42. Later there was pleurisy, and diarrhœa commenced. At 43 the left ankle swelled and was painful, but became quite well in a few months without special treatment. The right shoulder became painful and stiff at 44, and then the left. At 46 major tuberculosis of the right hip occurred, there was much pain, a sinus formed after a while, and a piece of bone came away. At 47 there was vomiting and hæmatemesis, pain in the right foot and hip, and another abscess formed in connexion with the right hip. At 48 she had tuberculous meningitis and was unconscious for a week, but she made a good recovery, and at 49 still lives. It cannot be said that the several operations were of any real benefit to this patient.

CASE 4.—Female, had pleurisy with effusion at 16. The left elbow swelled and discharged at 17, as did also the right wrist, after two aspirations. This wrist healed with a perfect functional result in about three months, and has not relapsed. At 18 there was pain and swelling of the right shoulder which subsided in a few weeks. Later in that year she was delivered of an illegitimate child; this delivery was followed by a severe relapse with remittent pyrexia, emaciation, and a copious discharge from the left elbow, which became flail. The shoulders and the right elbow became also affected, but cleared up rapidly and perfectly without special treatment, except the right shoulder, which remains stiff. The left elbow was put up in plaster in the extended position, and unfortunately is now ankylosed in that position. At 21 she married, has now just been confined a second time, and is in good health.

CASE 5.—Male, when 16, developed a tuberculous abscess in the upper and outer part of the left forearm, which was opened. The dorsum of the left hand then became affected, then the left great and second toes, which opened spontaneously. At 17 the left ring-finger became diseased, and at 18 an abscess formed over the inner side of the left hand, and another over the right wrist, which burst, leaving sinuses. Two toes were removed. The axillary glands were next noticed to be affected, and a swelling of the left knee developed, for which nothing was done, but which subsided in a few weeks. The patient wore splints for the wrists on and off for a few months. He worked intermittently, even when splinted; at 21 he commenced regular work as a shop-assistant, and has continued since. The wrists were then still troublesome, but are now healed, with a good functional result.

Monarticular, Major and Minor Types.

The consideration of the above cases leads us to minor tuberculous arthritis, a condition which has escaped definite recognition, though many surgeons tell me they suspected its existence. We have seen the occurrence of arthritis in one or more joints, in patients undoubtedly tuberculous, which yet clears up rapidly and spontaneously. Other joints apparently exactly similar progress to a major tuberculous arthritis. We will now consider cases in phthisical patients, and others, where the disease was monarticular and minor, and yet seemed clearly tuberculous.

CASE 6.—Boy of 7, with a tuberculous father, and living under bad home conditions, developed definite rigidity and tenderness of the dorsilumbar spine; he was notified as tuberculous and seemed a typical case of early Pott's disease. The boy had also extensive enlargement of the cervical glands, which was considered tuberculous. In three months, although no special treatment had been adopted, there remained only a slight stiffness. One year later the spine seemed normal.

CASE 7.—Female child, living with a tuberculous grandmother and aunt, was operated upon at 2 years for tuberculosis of the left thumb, left great toe, and left epitrochlear gland. At 3 she developed a limp, pain in the left hip, and weakness of the left leg. There was no obvious deformity or loss of movement and the child was well in two months.

CASE 8.—Female, aged 35, who had been in a sanatorium for phthisis (stage 2), and whose sister has a tuberculous knee, developed pain and stiffness of the left knee. When seen there were a slight fullness and tenderness on the inner side of the joint, but in a month or so it again seemed normal.

CASE 9.—Female, under treatment at 12 years of age for a tuberculous hip. For one month she was confined to bed, then seemed better and got about again, remaining only a little lame. At 32 this patient developed phthisis, with a positive sputum; there was then a just discernible stiffness of the left hip.

CASE 10.—Male, with a tuberculous wife, had swelling of the left knee at 33, diagnosed as tuberculous. Scott's dressing was applied for six weeks, then plaster for eight weeks. The joint then appeared well, and he commenced to use it; within two weeks a slight effusion recurred; movements, however, remained free and painless. A week or two later the joint was normal again, and has remained so for six years.

CASE 11.—Male, a labourer, aged 33, came to my surgery, when I was in practice, complaining of pain in the back, and indicated the region of the right sacro-iliac joint. On separating the iliac crests slight but definite pain was referred to that joint. I made some notes, entering as the diagnosis "sacro-iliac arthritis," and treated him symptomatically. He returned to work about a week later, and worked regularly for some two years. He then developed an obvious tuberculosis of the right sacro-iliac joint, which I trephined and scraped, and later treated him with tuberculin. The patient did not do well, suppuration spread into the buttock and down the thigh, but he made a good recovery after four years in hospital, during which he was sometimes extremely ill, and has now worked regularly for seven years. His disability is negligible. No merit is claimed for the treatment, but it was considered to be up-to-date at that time. Here a minor tuberculous arthritis became major after two years.

CASE 12.—A boy of 4 had pain in the left hip and limped. His father, who had lost two brothers with tuberculous hips and had, to some extent, lost faith in doctors, kept him lying down for a few days, then allowed him gradually to get about again. There was no further trouble in that joint; but two years later this boy developed major tuberculosis of the right knee, which ended in resection of the joint.

When calves are injected with living tubercle bacilli for experimental purposes I am informed that they sometimes develop a more or less transitory swelling of one or more joints. Fluid from these joints has been found to cause tuberculosis in guinea-pigs, and in some of them appearances indicating tuberculosis have been found post mortem.

I consider the case proved for minor tuberculous arthritis, and would sum up the proofs thus:—

1. The occurrence of more or less transient joint swellings in patients with several joints obviously affected.

2. The occurrence of what appear to be definite tuberculous joints in tuberculous subjects, which yet clear up rapidly and spontaneously.

3. The fact that some such joints may get well and then relapse, ultimately to become typical cases of major tuberculosis.

4. Animal experiments.

It must be borne in mind that between major and minor tuberculosis there is no sharp line and that all grades of intermediate cases may be seen.

Now consider other polyarticular forms of tuberculous arthritis.

(A) *Polyarticular Rheumatoid Type.*

This type closely simulates rheumatoid arthritis.

CASE 13.—A labourer, aged 55, with three tuberculous children, one of whom has since died, was seen as a contact, in bed, with "rheumatoid arthritis." He had been ailing for four or five years, getting thinner and short of breath. For nine months there had been pain in the right hip, and for a lesser period in the other hip, elbows, shoulders, knees, and wrists. The joint pains were severe. Pulmonary tuberculosis was obviously present, and there were fusiform swelling and tenderness of all the larger joints and some of the interphalangeal joints, but for the most part these escaped. He died of hæmoptysis one month later.

CASE 14.—Female, seen as the contact of a tuberculous daughter, who has since died. At 41 there were pain and swelling of the right elbow, then the right ankle, and by 42 the knees, elbows, shoulders, wrists, and ankles were very tender with a slight effusion into the joint and periarticular thickening. The condition was typically "rheumatoid." At 44 the carpometacarpal joint of the right thumb became affected; there was also pulmonary tuberculosis, with a positive sputum. At 45 several finger- and toe-joints were affected, and also the spine, but the atlanto-axoid joint and the hips still escaped. She died at 46.

(B) *Polyarticular, Osteoarthritic Type.*

In this the fusiform swelling, the sweating, and general symptoms of rheumatoid arthritis were absent; but lipping of the ends of the bones, and the appearance of the joints would justify a diagnosis of osteoarthritis. I believe the joints which my chief used to show me, when house surgeon, as "osteo-arthritis becoming tuberculous," were really examples of this type of tuberculous arthritis.

CASE 15.—An alcoholic steelworker was troubled at the age of 33 with swelling of the right knee. There was not much pain, but the swelling increased, lipping of the bones developed, and at 34 an operation was performed and some Baker's cysts removed. He resumed work but the other knee became affected, and at 37 I removed some Baker's cysts on that side; the appearance of the fluid was that usually associated with tuberculous joints. However, he was much improved and worked again for over a year, when gradually increasing swelling of the knees again incapacitated him. This time the fluid was aspirated and firm pressure applied, after which the patient resumed work for another year. Swelling then recurred, and pyrexia; signs of pulmonary tuberculosis were found, and later a pleural effusion formed, and swelling and pain took place in other joints—ankles, shoulders, wrists, hips, and elbows. The patient died of tuberculosis at 41.

CASE 16.—Male, with somewhat extensive signs of pulmonary disease, complained, at 23, of intermittent swelling of the fingers, knees, shoulders, elbows, and wrists. When first seen there was pyrexia, 100·5° F., a pulse-rate of 132, and respiration-rate of 24, but the joints were not then swollen. Three months later swelling of the right hand was found, and one year later the right wrist, right ankle, and the small joints of hands and feet were affected. There were stiffness and pain but no deformity.

CASE 17.—Female, as a girl of 13 had a tuberculous left hip and was under treatment for four years before arrest of disease took place with ankylosis and shortening. Lung symptoms and signs developed at 21, and a few years later abdominal tuberculosis led to two months in hospital for intestinal obstruction. Later again this patient was in bed 10 months for "gastric ulcer." Then other joints became affected with a condition diagnosed as "osteoarthritis," for which the patient underwent treatment in different institutions. At 30 there were signs of somewhat extensive pulmonary tuberculosis. There was fibrous ankylosis of both knees and right wrist and shoulder, also stiffness and pain of varying degrees in the ankles, left shoulder, and jaw.

(C) *Polyarticular, Arthritis Deformans Type.*

Arthritis deformans is often described as a different entity from osteoarthritis as generally recognised. The following are cases of tuberculous arthritis deformans:—

CASE 18.—A sailor of 18 injured his right knee, which swelled up a few days later, but did not prevent work. Three months later he had to lie up, and was admitted to hospital six months after the onset, with the diagnosis of tuberculous knee, urethral sources having been carefully eliminated. He was treated with tuberculin. Subsequently swelling occurred of the left wrist, right elbow, and left knee. There was a local and general reaction to each dose of tuberculin. I saw him at 19 with an effusion into both knees, left wrist, and right elbow, and a pyrexia ranging from 98°–101°. At 20 the right shoulder and jaw, both hips, ankles, knees, wrists, and right elbow were affected. The pain was very severe, the patient helpless and bed-ridden. Later pleurisy developed, then swelling of both ischial bursæ. At 21 there was left iridocyclitis. Extreme deformities of feet and hands gradually took place. The tibiæ became displaced backwards and outwards on the femora to a remarkable extent, obstructing the popliteal vessels, and causing in the end, at 24, gangrene of both legs, from which this patient died.

CASE 19.—Male, aged 21, was under treatment during two and a half years for tuberculosis of the right hip. At 27 there was a first hæmoptysis, and swelling occurred of the left middle finger, left ankle, and right knee. From this time onwards a cough and joint pains were a constant trouble. At 39 the cervical spine became affected as well as the joints already enumerated, and an osteophyte was noticed on the inner side of the left ankle. At 40 an osteophyte was noticed in the right groin. At 42 all interphalangeal joints were affected and ulnar deflection commenced. Now, at 44, exacerbations of lung or joint trouble still occur, and there is occasional hæmoptysis. This patient carries on intermittent work as insurance agent. Rest in bed improves his general condition rapidly, but makes his joints stiffer and more painful, so he prefers to remain about when physically possible.

Next consider the type of case to which the name tuberculous rheumatism may justly be applied. The condition may occur as fleeting joint-pains, or swellings, in tuberculous subjects, or we may get the picture of an attack of acute rheumatism, which, however, does not yield to salicylates.

CASE 20.—Female, aged 24, with pulmonary tuberculosis of medium extent, was in bed for three months, suffering from what seemed typical rheumatic fever. There were pyrexia, swelling, and pain of the joints which flitted from joint to joint. She made a good recovery; she has married twice since then and has had no further joint trouble.

Lastly, consider a series of cases which may be bunched together under the heading—

Aberrant Forms of Tuberculous Arthritis.

1. *Intermittent Hydrarthrosis.*

CASE 21.—A boy of 13 developed a swelling of the left knee. He recovered after five weeks and remained well until 15, when there was again swelling of the knee lasting a few weeks, and also a somewhat extensive pleurisy and physical signs of pulmonary tuberculosis were discovered.

I also remember a girl of about the same age in whom both knees were swollen intermittently and the diagnosis seemed to be tuberculosis, but in this case we had not the support of a pulmonary lesion.

2. *Extra-articular Arthritis.*—In these cases I think the main joint cavity remained clear, and the disease was confined to bone on the outer layers of the synovial membrane.

CASE 22.—Female, aged 17, whose right knee began to give way and was found to be swollen. She had been in bed five weeks when I saw her, and the knee was hot and stiff, but only swollen on either side of the ligamentum patellæ. A back splint had been applied. The patient remained in bed three weeks longer, then was about in a bath-chair for four weeks, after which she discarded the splint and began to walk. An abscess formed and discharged, leaving two sinuses. The sinuses healed in eight months, while the girl continued at work as a shop assistant, wearing a bandage only. The joint remains cured and functionally perfect after an interval of three years.

CASE 23.—Female, aged 16, twisted her left knee; some weeks later gradually increasing pain and swelling occurred. Eight weeks after the injury the patient had to lie up. I saw her two months later again, there were pain and some stiffness of the left knee, and a swelling on the outer side anteriorly below the midpatellar level which seemed in the synovial membrane. Gradually the swelling softened, and burst a few weeks later. The sinus closed in a few weeks and, except for a scar, the joint is now normal two years after the illness.

3. *Dry Ankylosing Arthritis of the Shoulders.*—This condition occurs not infrequently in phthisical patients.

CASE 24.—Female, aged 55, with moderately advanced phthisis; her mother, two brothers, and two sisters had died of phthisis. She was sent to a sanatorium and from there to an asylum because of mental trouble. She married after a few months at the asylum, at 57; 18 months later there were fibrous ankylosis of the left shoulder and partial ankylosis on the right side.

One might also include in this class cases of *capricious resistance*, in whom the resistance seems to vary within wide limits with, or without, a definite cause.

CASE 25.—Female, aged 21, who had suffered from cough and a "weak chest" since 14 and had never been able to work, developed an exacerbation of her phthisis after the birth of an illegitimate child. The left knee became tuberculous a few months later, and when seen six months after the confinement was a typical tuberculous knee. No splint was used, but the patient was confined to bed with pyrexia for about six months. She then got up and began to get about again, and soon after took a daily situation as nursemaid. Nine months later the disease of the knee was quiescent.

Classification.

The classification I would propose, then, for tuberculous arthritis comes under four main headings:—

1. Monarticular tuberculous arthritis, which may be subdivided into (*a*) major, and (*b*) minor arthritis.
2. Polyarticular tuberculous arthritis, which again may be subdivided into the following types: (*a*) suppurative, (*b*) rheumatoid, (*c*) osteoarthritic, (*d*) arthritis deformans. (*c*) and (*d*) may, indeed, be included in one sub-group, but as some would differentiate between them, I have made two headings.
3. Tuberculous rheumatism.
4. Aberrant forms of tuberculous arthritis.

It is not claimed that this classification is anything more than a mnemonic, as are all classifications. The classification adopted by Poncet and Leriche, whose monograph on this subject I purposely did not read until my own conclusions had been reached from clinical observation, seems much too complex; and far from serving as a mnemonic would itself need a similar aid. Moreover, though Poncet and Leriche give a most interesting series of observations, they claim more, I think, for tuberculosis than is justified; in this paper only cases observed personally are included.

Treatment.

Attention will be confined to the first group and sub-group, major monarticular arthritis—that is, tuberculous arthritis as universally recognised; otherwise we should be led too far afield.

First, it is generally acknowledged that the results of operative measures are bad, and that these should only be resorted to exceptionally. It will also be admitted that in the presence of active disease, accompanied by pain and muscular rigidity, rest in bed and extension are the best remedies until activity subsides. The extension should be in the axis of the limb segment below the deformed joint and is gradually altered as the limb strengthens. Theoretically it is harmful to apply extension in any other way, but Nature is very adaptable, and I have seen relief follow so often when this rule was disobeyed that it cannot be considered essential, only preferable; and in the case of a deformed spine no method of extension can really succeed in this. It is, however, open to discussion if the aim of treatment should be *ankylosis of the joint in a suitable position* as is frequently stated, when so many untreated, or partially treated cases end in arrest of the disease and yet a functionally perfect result. Complete immobilisation, as in plaster, has its dangers.

CASE 26.—At the end of one December a healthy, robust female of 30 slipped from a stool on to the flat of her right foot. Pain followed, but the patient continued working for a few days, until increased pain temporarily prevented her using the foot. It was bandaged and immobilised in splints, but when they were removed pain remained, and finally for two to three months plaster was applied as tuberculosis was suspected. I saw her the next May, at which time she was confined to a bath-chair. The right leg and foot were cold, blue, and œdematous, and movements were painful, but there was no muscular rigidity. The condition seemed purely functional and not tuberculous. X rays confirmed the diagnosis, but showed a remarkable thinning and lessened density of all the bones of the affected foot. Massage, passive and active movements were adopted and persevered with, in spite of pain and discomfort. The inner side of the boot was raised and an instep support ordered for a time. At the end of a month this patient could get about well, and in three months was normal again and could discard her supports. Had active treatment been adopted early the disability would probably not have lasted more than two or three weeks.

The bones, and most likely all other tissues, and at all stages of life to a varying extent, are in a state of flux, old bone being absorbed and new deposited. Immobilisation results in side-tracking the circulation and wasting of muscles, ligaments, soft tissues, and bones. It seems doubtful if under such conditions the products of tuberculous inflammation can be adequately removed even when resistance has been raised and the tubercle bacillus defeated; so fibrosis, rather than resolution, follows.

When heliotherapy first became fashionable I suggested that one of its advantages was that it would lead to less complete immobilisation of tuberculous joints. I now read in an article by Rollier, "Plaster was finally abandoned in favour of apparatus which provided sufficient immobility without interfering with the access of air and sun to the affected part." Kisch takes the joints off splints for passive movements at regular intervals.

No absolute rules can be laid down; ankylosis will sometimes result whatever is done, and plaster may be a most useful aid to recovery. (A tuberculous knee may do very well in plaster although the patient continues to walk on it.) But generally speaking *the immobilisation of a tuberculous joint should be relative and not absolute.* Such splints as the Thomas knee and hip-splints, and simple spinal supports, seem to give better functional results than absolute fixation, either in plaster or in accurately fitted celluloid splints. In the treatment of abscesses there will probably be no difference of opinion that aspiration, as practised at, say, Alton, gives much the best results. Perhaps there is now a tendency to rely more on simple aspiration and less to inject substances into the abscess cavity, which certainly increases the risk of a sinus. Time does not allow a detailed consideration of the treatment for each joint. Many points might be raised. For instance, is an extension-frame for spinal cases essential? Would not simple rest in bed be sufficient, especially if the patient were maintained in the supine position? (It may be remarked that the prone position is also useful.) Such splendidly managed and up-to-date institutions as Alton or Leasowe might give us some useful *controlled* observations on the point.

Short Cuts.

The question of short cuts in the treatment of tuberculous joints needs careful consideration. Three years or more has been laid down for the cure of a tuberculous hip, yet cases often abandon treatment voluntarily, or on the advice of some practitioner, and the result is functionally excellent. Now and again a relapse results, and it is the relapse, rather than the case that has neglected advice and got well, that comes to the notice of the specialist. But a relapse resuming strict treatment is often speedily quiescent again. Here are a few instances of short cuts:—

Case 27.—Male, aged 6, with diagnosis of a tuberculous hip, confirmed definitely by X rays. He was three months in hospital, and then discharged with a Thomas hip-splint and patten. He discarded both these within six months, and has remained well since. Now, at 12, the joint in functionally perfect.

Case 28.—Female, aged 15, had swelling and pain in the left knee at Christmas, 1915. It improved, but was again affected towards the end of 1916. She did housework intermittently and with difficulty. In June, 1917, she had to lie up, with night pains and the typical picture of a tuberculous knee. For nine months she wore a Thomas knee-splint, then discarded it and used the joint. There was no relapse. Now she is married and has one child, and the knee is functionally normal.

Case 29.—Female, aged 22, suffered from pain in the back for some months, which occasionally kept her awake at night. There was a slight projection of the dorsilumbar spines and tenderness on percussion in this area with rigidity of the muscles. Pott's disease was diagnosed, the patient was put to bed and kept on her back. The pain gradually subsided and after six months, she got up and the spine has since remained normal (three years). She wears no apparatus other than a rather high pair of corsets.

Case 30.—Female, aged 10, was treated for some months for tuberculous disease of the left knee. At 16 swelling of the right ankle occurred which burst and discharged for a short time. I saw her two years later because of a suspected recurrence of disease in the ankle. The right ankle was swollen and hot—1½ inches more in circumference than the left. Plaster was advised, but refused, and after resting a few weeks she recommenced work as a domestic servant and has worked continuously for four years, the ankle bandaged and occasionally painful, but functionally useful, though not perfect.

Case 31.—Fisherman, aged 26, had pleurisy on the right side; and at 27 he had pleurisy on the left. There were signs of pulmonary tuberculosis of medium extent, and tubercle bacilli were present in the sputum. The patient was sent for three months to a sanatorium. Next the right knee became swollen, stiff, and painful, and seemed clearly tuberculous. A splint was advised, but refused, and the patient returned to sea, after resting a month or two. The right knee was normal 13 months after the onset, and remained so. Tuberculosis of a right costal cartilage then occurred, which burst and discharged for a few months. At 30 there was double "sciatica" and back pain with marked rigidity of the lumbar spine, but the patient continued at work, and after a few months this also cleared up. Unluckily at 32 a marked exacerbation of pulmonary disease took place, and he died at 33.

Case 32.—Female, aged 18, had pain in the back, and her doctor diagnosed lumbar caries with an abscess. Another doctor was consulted who agreed with the diagnosis and opened the abscess in his surgery, liberating one and a half pints of pus. I saw her with a sinus and agreed that spinal tuberculosis was present. The sinus healed in a few months and she has remained well since (six years). She is now married and has one child.

Case 33.—Farm labourer lost his wife from pulmonary tuberculosis when he was 44. At that time he began to suffer from severe lumbar pain and, although treated with liniment and medicine for two years, had great difficulty in continuing at work. At 46 the right shoulder swelled, and when seen by me there was tuberculosis of the lungs and of the right shoulder, with suppuration, as well as a *marked* Pott's curve in the upper lumbar region. The shoulder was operated upon, and is now ankylosed, but a sinus persists. The back has been painless for over a year.

Case 34.—Female, aged 9, had pulmonary tuberculosis and was very ill. When seen there were rather extensive signs, the temperature was 101°, the pulse-rate 132, and the respiration 35. Gradually she improved, but at 10 there were pain and stiffness of the right hip, and subsequently a swelling appeared in the right buttock. She was in bed one month, then gradually began to move about again. Six months later the swelling had disappeared. At 11 (one year later) she could walk three miles a day. At 12 there was still a prominence noted in the right groin, and fullness of the veins. At 13 this had disappeared, and the patient has been normal since—2 years. She attended school regularly after two years' absence until the time came to leave.

It is impossible to be dogmatic when treating a disease of infinitely varying virulence attacking patients with widely different and ever varying resistance; but in the days to come it is likely that the reputation of a surgeon dealing with tuberculous joints will depend on his knowledge how and when to take short cuts. There seems to come a period during the treatment of tuberculous joints when the tide turns and the patient's resistance begins to defeat the bacillus. This is the time, when the enemy is "on the run," that movement may be commenced whether sinuses are present or not; but I hesitate to give any method for detecting this period.

Finally, I will cite a case of obstetrical as well as surgical interest.

Case 35.—F. H. commenced treatment for tuberculous hips when a girl of 3. Disease of the spine developed about 5, and subsequently a lumbar abscess was incised. The disease became arrested in spine and hips, but the hips were left ankylosed in the adducted position, so that the internal condyles of the right and left femora were in contact and walking difficult and ungraceful. At 23 she married a sailor, and at 27 became pregnant. It seemed unlikely that this child would be born alive without a Cæsarean section, as has been done in such cases, but after what the patient called a "terrible" time the child was born normally. The movement of the hips has improved, and the knees can now be separated over an inch and a half.

Summary.

1. A new classification for tuberculous joints is suggested.
2. Minor tuberculous arthritis is described.
3. Relative rather than absolute immobilisation for tuberculous joints is advised.
4. Short cuts in the treatment of tuberculous arthritis are discussed.

THORACIC SURGERY: WAR LESSONS IN CIVIL PRACTICE.

By R. P. ROWLANDS, M.S. Lond., F.R.C.S. Eng.,
SURGEON TO GUY'S HOSPITAL.

The surgery of the thorax has been greatly stimulated and advanced by the late war. The enormous number of casualties and the unexpected severity and mortality of thoracic wounds inflicted by shells and bombs gave an enthusiastic band of workers (prominent among whom were Gask[1] and Duval) wonderful opportunities of acquiring accurate knowledge of the pathological results of these wounds, of improving our methods of saving life, and of preventing prolonged invalidism from later complications. These keen and devoted workers were able to establish military thoracic surgery on the sound foundation of accurate knowledge. They soon learnt that the dangers of general collapse from unilateral pneumothorax and of hæmorrhage from the lung had been greatly exaggerated, and also that the disastrous effects of sepsis could be very largely avoided by operating as early as possible—always within 24 hours—cleaning out the pleura and excising the damaged and infected wounds of the chest wall, pleura, and lung. Above all, they learnt the need and value of closing the parietal wound in layers, to prevent secondary infection, and of completely restoring the function of the lung by the abolition, without delay, of the pneumothorax. The terrors of chronic empyema are thus avoided. The prevalent belief that the costly pressure-chamber or the intratracheal insufflation anæsthesia was necessary for safe work in the major thoracic surgery was shown to be without foundation. Operations which had to be undertaken without these supposed advantages proved that the pleura could be freely opened without causing serious collapse.

The operations here described are: (1) The removal of an extensive sarcoma of the chest wall; (2) the removal of a large hydatid cyst from the lung; and (3) the thoracic treatment of diaphragmatic hernia.

Sarcoma of the Chest Wall.

Case 1.—Female, married, aged 48, was sent for operation by Dr. T. H. Davison of Odiham, in February, 1921. A swelling had appeared over the lower right ribs some 15 months before. It was then thought to be a lipoma, and the patient did not appear again for more than a year, when the swelling had greatly enlarged and had become fixed. When I saw her the growth was 5 inches long and 4 inches broad, and inseparable from the lower ribs.

Operation.—Ethyl chloride, warm ether, and oxygen were administered through an ordinary facial mask and a large elliptical mass of the whole thickness of the chest wall (including the tumour) was excised, thus making a very large opening into the right pleura. There was little, if any, shock. The whole of the right lung, which had partially collapsed, could be seen and examined, and the dome of the diaphragm, the wall of the pericardium, and the descending aorta were very evident. All bleeding having been arrested and the pleural cavity cleared of clots, the thoracic wall was closed in layers, pleura to pleura, muscle to muscle, and skin to skin. This was easier than was expected, for there was little tension upon the stitches. The patient did well, the wound healing primarily and the pneumothorax rapidly absorbing; there was no pleurisy or fever. The patient was able to travel home ten days later and has remained well ever since.

The growth was a slow-growing, spindle-celled sarcoma. It is too early to date to venture any opinion on the ultimate prognosis, but the case shows that a large part of the chest wall, including the pleura, can be removed without any undue risk, provided the latter can be satisfactorily closed at once.

Hydatid of Liver and Secondary Hydatid of Lung.

Case 2.—Female, unmarried, aged 26, was hit in the epigastrium by a hockey stick in 1913. Severe pain, rigidity, and collapse ensued and a ruptured viscus was feared, but gradual recovery followed. In 1914 an extraordinarily loud rub was sometimes heard over the base of the right lung. The patient could hear it herself and so could anyone standing near her. In 1916 her health was poor; there was slight hæmoptysis, fever, and dullness over the right base. Tuberculosis was feared, but X ray examination by the late Dr. Ironside Bruce revealed a large spherical opacity above the right lobe of the liver, below the diaphragm, and the heart was displaced to the left. There was no opacity to suggest involvement of either lung. There was a rub over the swelling and a leucocytosis of 12,000. In August, 1916, another radiogram showed that the cavity below the diaphragm contained air and liquid, and an operation was advised for draining the collection which was supposed to be a suppurating hydatid. (See diagram.)

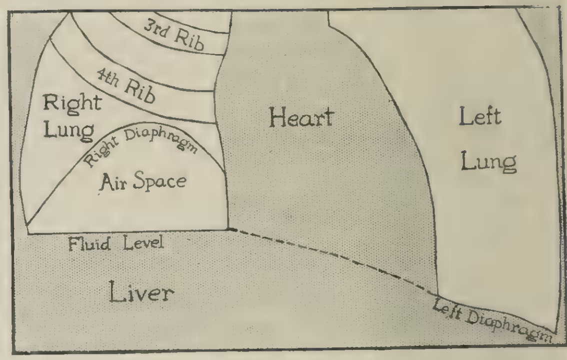


Diagram of Case 2.

Operation (August, 1916).—A needle was inserted just above the tenth rib in the line of the posterior scapula and passed into the cavity. It withdrew air and a clear watery liquid, which was shown by Dr. G. W. Nicholson to contain a large number of active hydatid embryos. Parts of the tenth and eleventh ribs and their cartilages were then removed below the pleura; the diaphragm was incised and a cyst, the size of a cocoanut, was seen projecting from the upper surface of the liver, high up and far back. This cyst was opened and was found to contain a very large number of other cysts of different sizes. They were removed and the cavity cleaned out and drained. Bile escaped for some weeks, but the patient made a good recovery.

In the summer of 1918, however, a large hydatid cyst had to be removed from the lower lobe of the right lung. Ether and oxygen were given in the ordinary way and the right pleura was opened freely, without any bad result. A hydatid cyst, the size of a large cocoanut, was shelled out and the cavity thus left was drained, for one of the bronchial tubes was opened and could not be closed. The patient made a good but slow recovery, the wound finally closing six months later. She has now remained quite well for four years, and in March, 1921, gave birth to a healthy child.

In the light of our present knowledge it is clear that the cavity in the lung could have been obliterated, the open bronchus closed, and the parietal wound sewn up completely, without drainage, with great advantage to the patient.

Diaphragmatic Hernia.

Case 3.—A male, aged 19, was admitted to Guy's Hospital in October, 1920. Seven or eight months previously he began to have pain, sometimes accompanied by vomiting, about an hour after meals. The pain used to be considerably relieved when in the recumbent position, but only when lying on the left side. Lately the period between meals and the onset of pain had become lessened, and when I saw him he was experiencing pain directly after meals. If the pain is not allayed he induces vomiting. There was much flatulence; no hæmatemesis; bowels regular; no respiratory distress at any time. About six months ago he was operated on elsewhere for supposed gastric ulcer. The stomach was found fixed high up in the epigastrium. The condition was not diagnosed and the abdomen was closed without further interference. Three weeks after the operation the pains became the same as before; they were in the epigastric and umbilical regions.

---

[1] Gask, G. E.: Trans. Med. Soc. Lond., 1921, xliv., 179.

Condition on Admission.—The patient was very thin and anæmic. P. 60. Temp. 96·8° F. Respiration 20. Abdomen: Definite sinking-in of epigastrium; abdomen moves well. No tenderness; no abnormality on palpation. Thorax: Lower ribs unduly prominent on left side in front and limited above by a sulcus running transversely (like a unilateral Harrison's sulcus). Patient had noticed this for the last six months. Chest otherwise looks normal. Heart: Apex one inch inside nipple line. No dullness to right of sternum. Sounds normal. Lungs: Percussion. Normal resonance over both sides except below scapula on left side, where note is tympanitic. Air enters all over both sides but voice sounds weak at left base. No borborygmi or metallic tinkling heard in chest.

X Ray Report.—First hour: The œsophagus passes down to the level of the lower border eleventh dorsal vertebra, and then turns to the left to join the stomach. The whole of the stomach lies above the diaphragm—the fundus behind and the pylorus antero-internally. The œsophagus enters the fundus at its lowest part. The motility of the stomach is good, and the meal leaves normally, but the duodenum does not appear to follow its normal course; none of the small gut appears to be above the diaphragm. Some of the opaque meal given on the previous day now seen in the splenic flexure above the diaphragm. Fifth hour: Stomach empty, meal in small intestine. Seventh hour: Meal in small intestine, none in cæcum. Thirtieth hour: Meal occupies large gut from cæcum to pelvic colon.

Operation.—Intra-tracheal ether, patient lying on the right side. An eight-inch incision made over eighth left rib, which was removed sub-periosteally and the chest opened, displaying a large serous cavity occupying the lower two-thirds of the left chest. Through the upper thin wall of this cavity the base of the lung could be seen, but it was not in the cavity. There was no distress on opening the latter, but it contained the whole of the stomach, the splenic flexure of the colon, and the spleen. There were some adhesions between the stomach, the great omentum, and the wall of the cavity, and especially between the spleen and the colon, and the back and left side of the cavity and the edge of the opening in the diaphragm. The stomach was rough, red, and bruised on the surface near the pylorus from friction against the front and inner edge of the opening. This was four inches long and one inch wide and was placed near the back of the diaphragm, extending downwards and outwards to the chest wall from near the œsophageal opening of the diaphragm. Its edges were thick and smooth. The anterior edge was much more definite than the posterior. The opening was clearly congenital and consisted of a slit between the lumbar and costal fibres. After separating the adhesions and tying many of them the viscera were returned into the abdomen and the opening in the diaphragm closed with many catgut sutures. The parietal opening was then completely closed without a tube. The patient was somewhat shocked after the operation, but revived after saline enemata. Pulse never went above 120. The wound healed well and he got up and walked about 14 days later. He improved greatly in health and put on weight. His symptoms were completely relieved.

X Ray Examination.—Report 18 days after operation: There is a large opacity at the base of the left lung which is probably caused by pleural thickening (? blood clot) in old hernial sac; the opaque fluid passes freely through the œsophagus and into the stomach, which is lying in normal position in the abdomen and shows no abnormality. Report 37 days after operation: Radiogram shows a marked diminution of the opacity in the left chest, indicating that the lung is expanding quickly; pictures were taken before opaque meal—i.e., there is no question of the thoracic opacities being due to bismuth.

These three cases illustrate the value in civil practice of lessons learnt in the hard school of war.

JENNY LIND HOSPITAL FOR CHILDREN, NORWICH. The vacancies on the surgical staff caused by the death of Mr. H. Whitwell and the resignation of Mr. T. J. Wright have been filled by the advancement to full surgeoncy of Mr. W. Watson and Mr. T. W. Hancock, and the appointment as assistant surgeons of Mr. G. S. B. Long and Mr. Philip Murphy. Dr. B. B. Morgan has been appointed honorary anæsthetist. Plans for a small casualty department are under consideration as well as the appointment of a second resident medical officer.

ON THE IDENTITY OF THE TOXINS PRODUCED BY SEROLOGICALLY DIFFERENT STRAINS OF *BACILLUS DIPHTHERIÆ.*

BY PERCIVAL HARTLEY, *M.C.*, D.SC. LOND.

(*From the Wellcome Physiological Research Laboratories.*)

HAVENS (1920) examined 206 strains of the diphtheria bacillus by means of a monovalent agglutinating serum and found that 169 strains (82 per cent.) were agglutinated by it in a dilution of 1/4860, and the strain used for the production of this serum was also agglutinated at this dilution. Thirty-seven strains (18 per cent.) failed to agglutinate. Accordingly a member of this smaller group was used for the production of a second agglutinating serum and it was found that all the members of this second group were agglutinated by this serum in a dilution of 1/4860. No evidence of cross agglutination was obtained; the two sera were specific for their respective groups. Havens also found that whereas the toxins produced by members of group 1 were neutralised by the antitoxin in common use (which is usually made from strain Park Williams No. 8 belonging to group 1) the toxins produced by the members of group 2 required very large amounts of antitoxin for their neutralisation. As a rule 20 units of standard antitoxin protected against one minimum lethal dose of group 2 toxin, while 5 to 10 units regularly failed to protect. Some samples of antitoxin, however, required to be used in much larger doses in order to neutralise one minimum lethal dose of group 2 toxin; in two cases 100 units were necessary, and in a third case even 1000 units failed to protect. Havens concluded from his experiments that standard antitoxin contains group antitoxin which protects against the toxins from both strains of the diphtheria bacillus, and that the amount of this group antitoxin, though never very large, varies in different samples.

Havens draws conclusions from his work which have a very important bearing on the preparation of diphtheria antitoxin and its practical use. He suggests that those cases which do not yield to treatment except by the use of very large amounts of antitoxin may be due to infection by organisms belonging to group 2. He also points out that, in spite of the increasing use of antitoxin and its administration early in the disease, the death-rate from diphtheria in America is still about 10 per cent., and this again may be due to infection by organisms belonging to group 2. Other procedures which, according to Havens, are affected by his results are the Schick test and active immunisation by toxin-antitoxin mixtures. As practical measures Havens recommends the inclusion of toxin from a member of group 2 in the routine preparation of antitoxin, the use of a mixture of toxins of both groups for the Schick test, and the use of mixed toxins and antitoxins for active immunisation.

Further Experiments.

Paxson and Redowitz (1922) repeated Havens's experiments and confirmed his results in so far as the occurrence of two serologically different groups of diphtheria bacilli are concerned. They were unable to obtain any evidence that the toxins from group 2 were not neutralised by standard antitoxin, and they concluded that antitoxin prepared from toxin obtained from group 1 strains neutralised equally well the toxins belonging to either group.

Park, Williams, and Mann (1922) examined five strains received from Durand (1920) who had shown by agglutination and absorption tests that they belonged to five different groups. Four strains belonging to Havens's group 2 were also examined. These workers fully corroborated Durand's results, and found that the four Havens's strains were not agglutinated by their type 1 serum, and they conclude "that in all communities there are many types and at least several dominant ones." They found, however, that the common antitoxin protected against living cultures of organisms belonging to five different groups, including three of Havens's group 2 strains and, further, that toxins prepared from members of all five groups were neutralised by the usual amounts of antitoxin.

The question of the identity of the toxin from different strains of the diphtheria bacillus and the efficacy of antitoxin arises from time to time in this country. It was stated in a recent report of the medical officer of health of one of our large cities that larger doses of antitoxin are required to-day to produce the same clinical improvement than were needed seven years ago, and it was suggested that this may be due to an alteration in the type or toxicity of the prevailing bacillus. A. S. G. Bell (1922), working at the Royal Army Medical College, investigated 130 strains of *B. diphtheriæ*, over 90 per cent. of which were isolated from swabs taken in the London area during a recent epidemic. An agglutinating serum prepared from strain Park Williams No. 8 agglutinated 17 (13 per cent.) of the strains. A second serum, made from a strain not agglutinated by the type 1 serum, agglutinated eight strains (6 per cent.), while a third serum, made from a strain which was not agglutinated by either type 1 or type 2 serum, agglutinated 80 strains (61 per cent.). Twenty-five strains (20 per cent.) were not agglutinated by either of the three sera prepared.

At Major Bell's request I undertook the study of the toxins produced by members of these three groups. The main object of the inquiry was to ascertain whether the toxins were neutralised by the antitoxin in common use which is made from the toxin produced by the Park Williams No. 8 strain.

Method of Present Test.

Fifteen strains, received at different times, were investigated. They were sown on 100 c.cm. quantities of the medium used in these laboratories for toxin production (1922, Hartley, P., and Hartley, O. M.) and after incubation at 37° C. for three days 0·5 per cent. of pure carbolic acid was added. The sterilised cultures were allowed to stand overnight in the dark and then filtered. Preliminary tests on the toxin were carried out by the intracutaneous method (Römer and Sames (1909); Glenny and Allen (1921)), the results of which showed that three of the strains had produced practically no toxin, that 12 had produced toxin in very variable amounts, and that all the toxins, irrespective of the group to which the strain belonged, were neutralised by the antitoxin in common use.

The results obtained by the intracutaneous method of testing indicated that eight of the toxins were of sufficient potency to admit of more complete examination by tests on the whole animal. Accordingly, the minimum lethal dose (M.L.D.), the dose which neutralised exactly one unit of antitoxin (Lo dose), and the dose which, when mixed with one unit of antitoxin, caused the death of the animal in 4–5 days (L+ dose) were determined in order to ascertain whether any toxin exhibited any unusual feature, and particularly whether the toxins from strains belonging to group 2 or group 3 required abnormally large amounts of antitoxin for their neutralisation.

The results of these experiments are summarised in the following table.

Seven of these toxins, although varying widely in potency, are very similar in composition, and the eighth (from strain "Swindon") differs from the others only in so far as the proportion of toxoid is somewhat less. There is no evidence that any strain produces a toxin which requires more than the usual amount of antitoxin for neutralisation. Post-mortem examinations were carried out on all the animals which died and all showed lesions typical of diphtheria poisoning.

The three strains "Swindon," "Phillips," and "Evans," when grown on liquid medium, exhibited several interesting features. These strains all belong to group 3—the largest of Bell's groups. Recently isolated strains of *B. diphtheriæ* usually produce toxin of relatively low potency. Theobald Smith and Walker (1896) studied the toxins produced by 42 different strains and found that the minimum lethal dose varied from 0·036 c.cm. to 0·12 c.cm. G. Dean (1913) states that the minimum lethal dose of toxins from recently isolated strains ranges from 0·1 c.cm. to 0·02 c.cm. and that on rare occasions the dose may reach 0·01 c.cm. The minimum lethal dose of the strains "Swindon," "Phillips," and "Evans" was 0·006 c.cm., 0·007 c.cm., and 0·009 c.cm. respectively. These three strains were also exceptional in so far as they all grew readily as surface films, and not throughout the medium, and they all grew very rapidly. It was possible to compare them under similar experimental conditions with strain Park Williams No. 8, the behaviour of which on the medium used was well known. This strain produces a complete film in 20 to 24 hours, but under the same conditions strains "Swindon," "Phillips," and "Evans" produced a film of equal density in 12 to 14 hours. The film produced by strain Park Williams No. 8 remained on the surface almost indefinitely, while the film produced by these three strains frequently sank to the bottom of the vessel after 18 to 24 hours' incubation, and shortly afterwards a second film began to grow. It is unfortunate that more strains were not investigated, as it would have been interesting to see whether rapid growth and the production of relatively large amounts of toxin were characteristics common to all members of this particular group of diphtheria bacilli.

Tests of Toxin from Different Strains of B. diphtheriæ.

Results Obtained.

The results are in agreement with those obtained by Paxson and Redowitz and by Park, Williams, and Mann. Further, these results obtained experimentally in the laboratory are in accord with the vast amount of clinical evidence concerning the efficacy of monovalent diphtheria antitoxin which has been accumulated during the last 25 years all over the world. It is reasonable to suppose that if different strains of diphtheria bacilli produced toxins which exhibited wide differences in their affinity for antitoxin, evidence—or at least indications—of this would have been forthcoming from workers studying diphtheria from the clinical side. As Park, Williams, and Mann point out, ever since diphtheria antitoxin has been used in practice hundreds of thousands of persons known to be contacts have been given practically complete protection for two weeks by the injection of monovalent antitoxin; and, further, routine virulence tests throughout the world have shown that a monovalent antitoxin protects animals against a dose of living culture fatal to others not given antitoxin.

VON WAGNER'S NEW TREATMENT OF GENERAL PARALYSIS.

BY ALEXANDER PILCZ,
PROFESSOR OF PSYCHIATRY AND NEUROLOGY IN THE UNIVERSITY OF VIENNA; CORRESPONDING MEMBER OF THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

IN many previous publications I have pointed out the results obtained by v. Wagner's treatment of general paralysis—i.e., the combination of artificial fever with a specific cure (mercury, &c.); at the International Congress of Ghent, in 1913, I came to the conclusion that the use of this method leads to remissions of (1) much greater frequency, (2) a much higher degree, (3) much longer duration than in the spontaneous remissions—i.e., in cases not treated. Although our results have been confirmed by the observations of other authors (Battistessa, Tamburini, Hudovernig, Glouschkoff, Myiake, Meyer, &c.), Wagner's tuberculin-mercury method seemed to require a correction. Patients who practically recovered—i.e., improved so much that they were able to devote themselves to their former occupations—often relapsed after a short time; in many cases, however, the remission persisted for from seven to eight years. After comparing the various methods of bringing about artificial fever, and thoroughly examining the cases of so-called "spontaneous remission," v. Wagner has drawn up a scale of efficiency as follows: (1) chemical substances (e.g., sodium nucleinate); (2) toxalbumins (tuberculin, typhus vaccine, staphylococcus, &c.): and (3) acute disease itself. Remissions in the course of, or after, an acute febrile attack being the most permanent and most intense, v. Wagner studied the possibility of provoking such an attack in order to facilitate a quick and certain cure.

Technique.

Von Wagner's new treatment of general paralysis is as follows: A patient is selected who suffers from tertian malaria (but not from tropical malaria), and who has not been treated by quinine (in order to avoid quinine-fast stems of plasmodies). During an attack of fever 2 c.cm. of blood are taken from the patient by venous puncture, and injected underneath the skin of the paralytic patient's back. After from one to two weeks, on an average, the first attack takes place, accompanied by shivering; the temperature rises to 40° C. and over. After some 10 or 12 attacks the malaria is checked by quinine during the first three to four days (0·5 g. quinine sulphate twice a day for three or four days, and then once daily for two weeks); at the same time a course of neosalvarsan is begun (intravenous injections once a week, commencing with 0·3 g., and working up to 0·6 g.). During the malarial attacks acoustic hallucinations, ideas of persecution, delirious and catatonic states are occasionally noticed, but all these symptoms will cease when the quinine cure is started.

Results.

Of 141 paretic patients, treated in 1919–20, 51 have completely recovered; 18 showed marked and persisting remission without being able, however, to return to their former occupations; 57 cases became stationary or showed an incomplete remission; 15 patients died. Omitting further details, for which I refer the reader to the publications of von Wagner and Gerstmann, I should like to mention that there is no parallelism in the degree and duration of the remissions on the one hand, and in the serological reactions (lumbar fluid, &c.) on the other. The best results are given by cases with the maniacal affections and by those of simple demency; the hypochondriacal, presenile, and catatonic forms of disease show a less favourable prognosis. Generally remission does not immediately follow treatment; it develops gradually, finally becoming permanent. I may add that this method is employed, not only in cases of general paralysis, but also in tabes and other forms of neurosyphilis; in disseminated sclerosis, also, good results have been obtained.

I hope that this brief note will be of interest to readers of THE LANCET—especially to general practitioners—who observe the paralytic patient in his early stage, and have, therefore, better chances of giving help than the alienist who generally has to deal with further advanced cases.

To emphasise the favourable influence of fever upon the paralytic process, I would call attention to two very interesting facts. Investigating the final histories of about 5000 soldiers who acquired syphilis in 1880–90, Mattauschek and I found 5 per cent. of paralytics. Of patients who had suffered from erysipelas, malaria, or other feverish diseases during the first year or two years after their primary sclerosis not one became paralytic; none of the patients who later became paralytic had such a feverish disease in his anamnesis. Further, we know the great differences of frequency of general paralysis and its dependence on race and climate: in the tropics the disease is proportionately much less frequent, although syphilis is there almost endemic. Perhaps this fact is connected with the endemic frequency of malaria, yellow fever, &c., among peoples dwelling in tropical countries. Perhaps, also, we may here find a hint as to the possible prophylaxis of general paralysis—treatment of the syphilitic patient not only by arsphenamin, &c., but also by artificial fever. In other words, von Wagner's treatment should be applied not only when general paralysis is already manifest, but also much earlier, in any case of secondary syphilis.

THE BACTERIOLOGY OF OZÆNA.

BY DR. KOZO SAKAGAMI,
TOKYO, JAPAN.

THE ætiology of ozæna has interested a number of workers in Europe and America, and a fairly extensive literature exists upon this subject. Up till now, however, opinions remain divided and no agreement has been reached. Recently very few bacteriologists seem to have taken an interest in this question, but it continues to be a live problem for the oto-rhino-laryngologists. To me it seems imperatively to require the coöperation of the bacteriologist, and I have engaged in research in this direction for several years. I succeeded in isolating various bacteria from the discharge from the nasal passage, and studied them carefully in regard to questions of biology, immunity, &c., in order to find out which of them might be a special factor in the ætiology of the disease. I came to the conclusion that there is some prospect of settling the question definitely, and, as I am fully convinced that bacteriology will some day contribute its share to the treatment of the disease, I give below an outline of the results of my studies, soliciting the criticism of my professional colleagues.

Results of Experiments.

The results of the various experiments may be summarised as follows:—

1. Among the seven different kinds of bacteria obtained from the nasal passages of ozæna patients, the most numerous were Gram-negative bacilli, occurring either above or in company with others;

less frequent are staphylococci, Gram-positive bacilli, and catarrhal micrococci; the others occurred in small numbers only. For convenience of identification I numbered the different kinds, calling those with the highest frequency No. 1 bacteria, those with the next highest frequency No. 2, and so on down to No. 7.

2. From my experiments regarding virulence, infection to animals, and immune reaction of the above, No. 1 bacteria appear to be by far the most potent; I have therefore devoted myself chiefly to the study of No. 1, and mention results obtained in respect of the others only for purposes of comparison.

3. As No. 1 type possesses the highest pathogenicity, I consider it to be the pathogenic bacteria of ozæna. It resembles fairly the coccobacillus described by Perez and Hofer, and I regard it as belonging to that genus.

4. Among the Gram-negative bacilli I observed Friedländer's bacillus and one closely resembling Abel's bacillus, the latter occurring in extremely small numbers. Most bacteriologists recognise three kinds of capsulated bacteria, with different degrees of mucus-production—viz., Friedländer's, rhinoscleroma, and ozæna bacilli, which, however, are only differentiated with difficulty. I myself have not been able to obtain any forms referable to the *Bacillus rhino-scleromatis*, but I think the so-called ozæna bacillus is very nearly allied to Friedländer's, although the two are not absolutely identical. There are, further, Abel's and Perez's bacilli, very similar in many points and disagreeing in others. It seems to me that all these bacilli represent one species, which, however, is separated into distinct races according to their origin. Among the coccobacilli obtained there is one closely resembling that mentioned by Abel. Among the No. 2 bacteria (Gram-positive bacilli) some are mucus-producing, some non-mucus-producing. The former, as far as immune reaction is concerned, have many points in common with the coccobacilli, which, however, are Gram-negative and quite dissimilar in respects other than immune reaction. The non-mucus-producing bacilli in certain respects resemble pseudo-diphtheria bacilli.

5. Among the coccobacilli it is possible to isolate two strains growing on milk, and four growing on sugar. As I am still continuing my experiments in this direction I reserve fuller details for later publication.

6. The virulence of the coccobacilli is of medium degree in mice, and weak in white rats, guinea-pigs, and rabbits. The virulence is not weakened by repeated passage through the same species of experimental animal.

7. In my animal experiments relating to infection with coccobacillus I was successful in reproducing the symptoms arising during ozæna in the human body—viz., stinking snivelly secretion, ulcerations on the outside of nasal ala and lower jaw, and abnormal formation of crusts.

8. My immunisation experiments with serum from ozæna patients and experimental animals show the following results:—

(i) *Bacteriolysis.*—(*a*) The serum from an ozæna patient is feebly bacteriolytic against coccobacillus, or quite inactive; (*b*) The bacteriolytic action of the blood serum of an immunised rabbit is weak against coccobacillus; it makes apparently no difference whether mucus-producing or non-mucus-producing bacilli have been used as antigens, and therefore, from a practical standpoint, either may serve as antigen.

(ii) *Phagocytosis.*—The blood serum from an immune rabbit or a healthy person shows a high opsonic index with the non-mucus-producing bacilli, but a low one with mucus-producing coccobacilli.

(iii) *Agglutination Tests.*—(*a*) The serum of ozæna patients shows a comparatively weak positive reaction against coccobacilli obtained from the same person; some sera, however, exhibit a notable action against other bacteria; (*b*) the rise in agglutinating power of the serum obtained from an ozæna patient after vaccine treatment, compared with that from the same patient before treatment, is quite remarkable, although the agglutinating power of a patient's serum never comes up to that exhibited by serum from an immune rabbit; (*c*) the serum derived from an immune rabbit shows a powerful agglutinating action against the coccobacillus; (*d*) the serum of a rabbit immunised with coccobacillus accompanied by mucus-producing and non-mucus-producing bacilli agglutinates remarkably well both the mucus-producing and the non-mucus-producing bacilli; (*e*) in experiments conducted by myself in analogy to Babes's agglutination test the serum of a coccobacillus-immune rabbit produced agglutination in a notable degree with coccobacillis, but not with Gram-positive or Friedländer's bacilli.

(iv) *Complement-fixation Tests.*—(*a*) The serum from an ozæna patient (before treatment) shows only in rare cases a noticeable positive reaction against coccobacilli obtained from the same patient, and it shows likewise a weak positive reaction against other bacteria; (*b*) the complement fixation of the serum from a patient after vaccine treatment never rises to that of the serum from an immune rabbit; on the contrary, the reaction remains in most cases either very weak or absolutely negative, though in a very few exceptional cases a strongly pronounced reaction was quite unexpectedly observed; (*c*) the complement-fixation reaction of the serum from an immune rabbit is positive in a remarkably high degree; (*d*) there is a great deal of mucous matter attached to coccobacillus colonies growing in culture-media, and this mucus can be removed by washing the colonies with salt water; if we use separately the washed colonies and the mucus-containing washing fluid for immunisation, and compare the sera obtained by their help with each other, as well as with serum obtained by help of unwashed colonies, we find as follows: With serum obtained by means of merely the washing fluid the complement-fixation reaction is positive, though weaker than is the case with serum obtained by means of washed colonies, and the use of unwashed colonies brings about a stronger reaction than that of washed colonies. It seems, therefore, that the presence of this particular mucus, far from impairing the production of immune bodies, has in fact a favourable effect.

(v) *Precipitin Test.*—The serum from a coccobacillus-immune rabbit shows positive reaction in a moderate degree.

(vi) Whereas the serum from an immunised rabbit is strongly positive against coccobacillus in both the agglutination and complement-fixation tests, the serum from an ozæna patient shows rarely a strong, generally a weak, reaction. Ozæna seems to be a purely local affection, and consequently the antibodies in the blood are produced in small quantities only. To make this still clearer, let us once more return to the animal-infection experiments: In rabbits that after infection with coccobacillus had shown marked pathological changes at first, but were manifestly on their way towards recovery, both agglutinating and complement-binding power of the serum were found to have risen to a high degree. But in other cases, where the pathological changes were limited to a small area or altogether absent, no positive reaction was shown at all. In other words, there is no immune reaction in cases where the pathological changes are slight or locally restricted; but if the initial pathological changes go beyond a certain degree, the serum shows during subsequent recovery the same strong positive reaction as that exhibited by serum from an immunised rabbit. By analogy it is easily seen why the serum of the great majority of ozæna patients shows at most a weak immune reaction.

Conclusion.

The results of my experiments may be briefly recapitulated as follows:—

1. The so-called ozæna-bacillus, obtained from the nasal passages of ozæna patients, agrees in all important points with the coccobacillus of Perez.

2. The coccobacillus is to be found only in ozæna patients, and not in persons suffering from other nasal diseases and healthy persons.

3. By experimental infection of the nasal passages of rabbits I was able to produce symptoms closely agreeing with those of human ozæna.

4. In the various immune tests with my coccobacillus the serum of ozæna patients generally showed a weak reaction; with some patients, however (i.e., those tending towards recovery), the specific reactions were remarkably strong.

5. It could be demonstrated that the serum from a rabbit immunised against my coccobacillus produces various immune bodies with great intensity.

6. In animal experiments with this bacillus the presence of immune bodies in the serum was clearly demonstrable; on the other hand, the reactions of the serum of most patients were rather weak. This can be explained from the nature of the disease, which causes merely local changes, so that in the general circulation the antibodies appear only in small quantities.

7. From the experiments relating to animal infection and immune reaction it appears that my coccobacillus may confidently be considered to be the causative agent of ozæna.

A CASE OF

PRIMARY CARCINOMA OF THE LUNG.

BY HENRY J. C. GIBSON, M.D. EDIN.,
MEDICAL SUPERINTENDENT, ROYAL INFIRMARY, DUNDEE;
AND
G. MARSHALL FINDLAY, O.B.E., M.D.,
D.SC. EDIN.,
LECTURER ON PATHOLOGY, UNIVERSITY OF EDINBURGH.

PRIMARY malignant neoplasms of the lung are by no means common. The case here recorded presents certain features of interest.

History.—The patient, a man aged 50, was admitted to Craiglockhart Hospital, Edinburgh, on Jan. 28th, 1922, complaining of pain in the stomach and swellings on the body. He had always been healthy, except for an attack of pneumonia, probably lobar, many years before. The present illness came on insidiously at the beginning of 1921—the first symptoms being languor, an occasional headache, and intermittent attacks of diarrhœa. In September, 1921, he first experienced acute abdominal pain, which was accompanied by vomiting immediately after food; about the same time he developed an irritating cough with much expectoration, and lost weight rapidly. He recovered somewhat, but continued to be confined to bed until admission. There was no family history of tuberculosis or malignant disease. The patient stated that he smoked and drank to excess.

Condition on Admission.—He looked ill, flushed, and emaciated; he was experiencing continuous, though not severe, pain in the epigastrium, right hypochondrium, and lumbar regions. Three subcutaneous swellings, varying in size from a pea to a hen's egg, were present—one on the anterior fold of the left axilla, one on the seventh right costal cartilage, and one mid-way between the umbilicus and xiphisternum; these tumours were not attached to the skin, were firm in consistence, and only slightly tender. Later, a fourth swelling appeared on the flexor aspect of the right forearm. They continued to increase slowly in size, with the exception of the neoplasm associated with the pectoralis major, which before death attained the size of a small melon. There was no fungation. A small portion, excised from the forearm, was examined histologically by the courtesy of the Royal College of Physicians, and reported upon as follows:—"Shows the structure of a squamous epithelioma, very rapidly proliferative. (The primary growth, if not in the skin, must be in a mucous membrane lined by squamous epithelium.)" A similar report was given on a fragment of tumour obtained from the anterior aspect of the abdomen. A careful search of the skin and of the junction of the skin with mucous surfaces for any primary tumour, ulcer, or cicatrix, was made, but the result was negative. Patient vomited occasionally after food. There was no œsophageal obstruction. Analysis of a test-meal showed the presence of hydrochloric acid, though in slightly diminished quantity; no blood was present. He suffered from diarrhœa occasionally. There was nothing to note on rectal examination. Albumin (no casts) and blood were present in the urine for a short period after he came under observation. Examination of blood showed R.B.C., 1,850,000; Hb., 25 per cent.; W.B.C., 14,000. The systolic blood pressure was 100 mm., and the diastolic 65 mm. of mercury.

Course of Case.—For the first six weeks after admission night sweats were troublesome, and during the same period the temperature was intermittent, with evening rises varying from 99° to 101° F. The sputum was moderate in quantity, muco-purulent, and at times nummular; it was examined frequently—no tumour fragments were seen, but on one occasion tubercle bacilli were found. During this period he had two hæmoptyses, such as one associates with pulmonary tuberculosis. Physical examination of the chest revealed definite disease of the right pleura and lung—retraction above and below the clavicle, impairment of movement of right side of chest, and dullness on percussion, increasing in intensity downwards from the level of the second thoracic spine, with vocal resonance and breath sounds decreased over the same area. A few moist sounds were heard at the right apex. There was no evidence of cavity formation. The right base was explored on several occasions, but no fluid was obtained.

From the beginning of March until his death on June 8th, 1922, although there was marked abatement of the symptoms referable to pulmonary tuberculosis—e.g., cough, spit, and night sweats—the temperature remained subnormal, the area of dullness on the right side of the thorax slowly increased in size and intensity, and his condition became more typical of the cachexia of cancer. It was considered that the neoplasm might have its primary site in the right lung, but having regard to the pathological reports on the metastases, such a conclusion remained a matter of conjecture until the post-mortem inspection.

Post-mortem Examination.

There was a considerable degree of emaciation. A small subcutaneous swelling, about the size of a cherry, was present in the epigastric region, 3 inches below the xiphisternum and 1 inch to the left of the middle line. A second subcutaneous swelling, the size of a large orange, was present over the anterior aspect of the left pectoral muscles, 2 inches above the left nipple. A third swelling was embedded in the flexor muscles of the right forearm, 3 inches below the right elbow. On section all these swellings were of firm consistence, white, with scattered areas of a deep yellow colour. They occupied the cutis vera and subcutaneous tissue.

Thorax.—There were recent pleuritic adhesions on the left side. The left lung was very deeply pigmented with carbon, but there was no evidence of tubercle. It showed evidence of emphysema, congestion, and bronchitis. The lymphatic glands at the root were enlarged and pigmented. The right lung was firmly adherent to the parietal pleura, and could only be separated from the chest wall with considerable difficulty. On section of the organ there was seen a large whitish mass about the size of a cricket ball extending from the root outwards into the lung tissue. The remainder of the lung was congested and œdematous. The lymphatic glands at the root were enlarged and pigmented with carbon. The pericardial sac contained about 20 c.cm. of clear straw-coloured fluid. The heart was small; the subepicardial fat showed some myxomatous changes, while the coronary vessels were very tortuous and thickened. The valves of the heart were quite healthy. There was slight arterio-sclerosis in the aorta.

Abdomen.—A small white nodule of tumour growth was present in the right rectus abdominis muscle. There was no increase of peritoneal fluid. The liver was not enlarged, but showed some congestion. The spleen was slightly enlarged and deep red on section. The œsophagus, stomach, and intestines were normal. The mesenteric glands were enlarged, matted together, and whitish on section. The right kidney was normal in size, pale on section; there was a small white nodule, the size of a hazel-nut, in the cortex. The left kidney was normal in size; attached to its lower pole was a white lump of neoplastic tissue about the size of a walnut. The right adrenal was nearly three times the normal size; it was not adherent to the kidney; on section there was only a narrow rim of cortical tissue left, the rest of the gland being replaced by a homogeneous white mass. The left adrenal was also enlarged, and contained two small white nodules similar to that in the right adrenal. The pancreas contained a small white nodule at the junction of the head and body of the organ. The thyroid, parathyroids, testicles, bladder, seminal vesicles, prostate, and bones were all normal.

Microscopical Examination.—The primary lung tumour was composed of cylindrical columnar cells, arranged for the most part in papillary-like tufts. Much of the tumour had undergone a myxomatous type of degeneration. No evidence of a tuberculous process could be detected in either lung. A columnar type of cell was found in the pancreatic metastasis. In the adrenals, however, the cells showed more irregularity in their shape; some were columnar others definitely polyhedral, while the general arrangement was more diffuse. In the secondary growths in the skin and muscles a definite squamous metaplasia had taken place; all transitional types of cell were noted, from columnar epithelium to squamous epithelium, the latter, arranged in cell masses, resembling those found in a typical squamous epithelioma. There was no actual formation of keratin by these squamous cells.

Remarks.

Squamous metaplasia of the bronchial mucosa is a not uncommon occurrence in tuberculosis and other pulmonary lesions. As a result a certain number of carcinomata arising from the bronchial mucous membrane are definitely squamous in type. In a few cases, as in those recorded by Kretschmar[1] and Henrici,[2] there was a mixture of squamous and columnar cells in the primary tumour, showing that metaplasia may take place in the established tumour. The present case is of interest owing to the fact that in the primary lung tumour—although this was preceded by a tuberculous lesion—there was no evidence of cell metaplasia; such a metaplasia was, however, well seen in certain of the metastases, notably those in the voluntary muscles and skin.

The distribution of the secondary growths is also of some interest. Adler (1912)[3] reports that the liver is invaded in 28·5 per cent., the adrenal in 10 per cent., and voluntary muscles in 2 per cent. of cases. In the present instance secondary metastases were absent from the liver, but were found in the pancreas, both suprarenals, kidney, skin, and voluntary muscles. The presence of skin metastases is of especial interest, since Suzuki (1918)[4] was only able to collect 115 cases of multiple skin metastases from cancer of internal organs, while in only three of these was the primary growth in the bronchus.

We desire to thank Mr. W. N. Boog-Watson for assistance in recording this case.

Clinical and Laboratory Notes.

DIABETES MELLITUS

IN AN INFANT AGED FIVE MONTHS.

BY HUGH T. ASHBY, M.D. CAMB., M.R.C.P. LOND.,
PHYSICIAN TO THE MANCHESTER CHILDREN'S HOSPITAL, ETC.

THE following case is interesting on account of its rarity in a child so young.

History.—The baby, a female, aged 5 months, was seen by myself and admitted to hospital on August 16th, 1922, with the diagnosis of pyelitis. She was said always to have been a cross baby and difficult to rear. Many different feeds had been tried without much success. The stools were offensive and frequent.

Condition on Admission.—She weighed 11 lb. 13 oz., and she had a dry, scaly skin, which seemed to irritate. The urine (catheter specimen) was acid and cloudy, and contained a small quantity of albumin. Microscopically pus cells and *B. coli* in large numbers were seen. She was put on an alkaline mixture and milk and water feeds, which she took greedily.

Course of Case.—During the first three weeks in hospital she gradually lost weight, had frequent loose stools, had a continuous rise of temperature, and was always restless. The urine became much clearer and less acid, though the temperature became higher, for which fact we could not account. At the end of the third week the second toe of the left foot became black and gangrenous. The toe seemed quite painless and it kept quite clean. The urine was at once tested for sugar with Fehling's solution, which was reduced in the usual way. Further tests were made by Dr. A. Sellers, our honorary pathologist; Trommer's test and the phenyl-hydrazin test confirmed the presence of reducing sugar. There was never enough urine to estimate with accuracy the amount of sugar or the specific gravity. Two days later the second toe of the opposite foot started in the same way. A fortnight later both toes came off and the surrounding skin became healthier, although at one time it appeared as if the whole foot on one side would become gangrenous. The loss of weight was slow but gradual, although the infant took her feeds well. Directly the sugar was found she was put on whole-milk feeds, without added sugar, and a sodium bicarbonate mixture. The urine contained glucose till she died, six weeks after admission to hospital.

Towards the end the skin over the trunk and limbs became pustular and the infant had a continuous rise of temperature. She had wasted nearly three pounds and she was comatose for the last four days.

A CASE OF

ENDOTHELIOMA OF THE MALE BREAST FOLLOWING AN INJURY.

BY H. K. GRIFFITH, F.R.C.S. ENG.

THE following case is interesting on account of the rarity of the disease and its relation to an injury.

The patient, aged 50, in April, 1922, received a blow from a horse's bit just above the right nipple. A definite bruise formed and slowly disappeared. This was seen by one of my partners on several occasions, and at the end of May had cleared up except for a definite cystic tumour, which was freely movable in the surrounding tissues and not attached to the skin.

When next seen in the beginning of July the following condition was found. A distinct swelling was visible 1½ in. above the right nipple, with an area of discoloured skin over it about 2 in. in diameter. In the centre of this area there was a bulla containing a little fluid, the skin just not being ulcerated through. Beneath this could be felt a hard nodular tumour 1½ in. in diameter adherent to the skin and to the surrounding tissues, but not to the underlying muscle. No glands could be felt in the axilla or neck. The patient was definite that no tumour existed before the blow, but I concluded that probably it was a case of cystic adenoma becoming malignant. The patient was healthy and well built, with a large amount of subcutaneous fat.

Operation.—I removed the breast with the underlying pectoralis major muscle, but as I could feel no axillary glands and had some doubt about the diagnosis I left the axilla for a future occasion if necessary. The patient made an uninterrupted recovery from the operation.

Histological Examination.—The breast was sent to St. Bartholomew's Hospital Clinical Research Department, where it was examined by Sir Bernard Spilsbury, and the following report sent: The tumour (macroscopically) was encapsuled, and did not infiltrate the breast tissue or the skin which was much stretched over it at one point. On cutting into it the substance seemed to consist of necrotic material of a caseous nature, white in colour. The sections show a degenerating endothelioma—masses of endothelial cells fading away in many places into the structureless hyaline degenerate material. Foreign body giant cells may be seen in many parts, and at one corner of one of the sections some old organising blood-clot may be found.

It seems very probable that the injury led to the formation of a hæmatoma, and the irritation caused by the presence of this blood-clot gave rise to so much endothelial proliferation that an actual tumour, an endothelioma, arose in that situation. The treatment by local removal should be quite sufficient, judging by the microscopical characters of the tumour, to effect a cure.

Torquay.

A NOTE ON

BARIUM IN THE HARROGATE WATERS.

BY A. WOODMANSEY, M.SC.,
ANALYST, ROYAL BATHS, HARROGATE.

BARIUM rarely occurs as a constituent of European mineral waters. This is due, no doubt, in some cases to the considerable amount of sulphates usually present, which with barium would provide a familiar instance of chemical incompatibility. The pharmacology of barium is well understood. While toxic in higher concentration, when administered in suitable doses it exerts a marked stimulating action upon all forms of muscular tissue and causes a gradual but sustained rise in blood pressure. Bain and Edgecombe[1] have shown that barium enables a purgative water to be taken continuously without resultant enervation. The substance is therefore a valuable constituent of the Harrogate waters in which it occurs. If, for any reason, barium is contra-indicated, one of the barium-free waters, of which there are several, would be prescribed. The following figures represent parts of barium per 100,000 in three important Harrogate springs: "Old Sulphur," 6·91; "Chloride of Iron," 3·51; "Magnesia," 3·97.

---

[1] "Harrogate Waters," p. 22.

The accepted dosage of barium chloride ($BaCl_2 2 H_2O$) is from 0·016 to 0·12 g., or 0·009 to 0·067 g. actual barium. This is the equivalent of 5–34 oz. of "Old Sulphur water." In spite of the insolubility of barium sulphate it is interesting to note that a very small quantity of sulphate is actually found in the above waters coexisting with the barium, to the extent of one part $BaSO_4$ per 140,000 in the case of the "Old Sulphur" and one part per 190,000 in the "Chloride of Iron."

According to Fresenius the solubility of barium sulphate in pure water is one part per 400,000. Certain salts—e.g., magnesium chloride and ferric chloride, increase the solution capacity of water for barium sulphate, and probably this explanation accounts for the ability which the above waters possess of holding barium and sulphate ions together in solution. These concentrations are, of course, very small and do not affect the general truth of the previous "incompatibility" statement, which has here a practical application. Experimental work in the Harrogate Laboratory has shown that sulphur water exposed to air undergoes several chemical changes, one of which is a slight but continuous production of sulphates, due to oxidation. If allowed to proceed practically all the barium is precipitated. Precautions are consequently taken so that the patients receive their mineral waters in the unaltered state.

TWO CASES OF
CONGENITAL HEMIHYPERTROPHY.[1]

BY DONALD PATERSON, M.B. EDIN., M.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON, W.C.;

AND

F. NEON REYNOLDS, M.R.C.S. ENG.,
CASUALTY OFFICER, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THE following are good examples of a rare congenital abnormality.

CASE 1.—A female infant, aged 6 months, was seen at the out-patient department of the Children's Hospital, Great Ormond-street. She was an only child and had had no previous illnesses. The father and mother are healthy. The whole of the left side of the body had been noticed to be larger than the right side. The skull showed no definite asymmetry, the zygoma, ear, and cheek were all enlarged on the left side. The left breast and thoracic muscles were better marked than on the right side. The left arm and leg were markedly enlarged, and the leg measurements were as follows: Circumference of thigh at gluteal fold, left 12 in., right 10½ in.; circumference of leg at knee, left 9 in., right 7½ in.; anterior superior spine to internal malleolus, left 10¾ in., right 10¼ in. The X ray shows a definite thickening and hypertrophy of the bones of the leg, the left tibia being definitely thicker and longer than the right. Apart from this condition no abnormalities were to be noted, and the child seems in every way normal.

CASE 2.—A girl, aged 13 years, presenting hemihypertrophy affecting part of the right side of the face. The parts chiefly affected are the zygoma, malar bone, and the superior maxilla, with the soft tissues covering them. The temporal bone and muscle are affected to a less extent, as are also the lower jaw and the masseter muscle. Measurement: External occipital protuberance to superior maxilla, right 11 in., left 10½ in. The ear and eye are unaffected; the discs are normal. An interesting feature is the condition of the teeth; the first permanent molar in the upper jaw on the right side is very large, but the corresponding tooth on the left is missing, so no comparison can be made. X rays show a general enlargement of all the bones of the skull. The rest of the body is unaffected and the child appears quite normal, mentally and physically. There is no history of trauma at birth; labour was normal. There are five other children, none of whom show any abnormality, the patient being the youngest but one.

Remarks.

This condition of hemihypertrophy is a very interesting one, and as around it centres the whole question as to what really governs growth, it has always excited a great deal of controversy. Various classifications have been given; false hypertrophy where the enlargement is due to an extensive nævoid or lipomatous growth of one side of the body or one portion of one side. In this type the soft parts only are affected, and the bones do not show thickening, nor is there lengthening of the limbs on the affected side. True hypertrophy, however, is the condition where all the structures are involved, including the subcutaneous tissue, muscle, and bone. In this type the limbs show lengthening as well as an increase in their girth. X rays show a true enlargement of the bones on the affected side. Arnold Gesell has collected 40 cases (reported up to 1921) of complete hemihypertrophy, where all the structures on one side of the body were involved, and 30 cases where the hypertrophy was partial and in some cases crossed, so that an arm was involved on one side and a leg on the other side. Gesell found that the hypertrophy was confined to the right side of the body in 70 per cent. of his cases and is slightly more common in males than in females. The condition is rarely seen in adults.

Along with this condition skin abnormalities such as nævi are sometimes found. Mental defect is also frequently associated with it. Many theories have been advanced as to how this hypertrophy is brought about, but few have anything to substantiate them. Dr. Robert Hutchison's case, which had a very complete post-mortem examination, showed a hypertrophy of all the internal organs on the affected side, especially the suprarenal. The side of the brain on the opposite to the hypertrophied side of the body has occasionally been found to be enlarged. It has been pointed out that the affected side looks older than the unaffected side, and that the carpus and teeth are seen by X rays to show hypertrophy and more advanced ossification on this side.

Some authors would attribute this hypertrophy to the action of the endocrine glands, and especially to the pituitary and the suprarenal. This is difficult to explain unless they act through the nerves, and the changes are then really neurotrophic. Fortescue-Brickdale reported a case in 1915, and argued that this condition was hypertrophy rather than atrophy for the following reasons: (1) The distribution of the enlargement was from a few digits to the whole of one side of the body, and it was thus absurd to think of the fingers being normal while the remainder of the body was atrophied; (2) cases of enlargement of opposite limbs are similarly difficult to regard as an atrophied condition of the whole body; (3) occasionally the smaller side was functionally more useful than the larger side; (4) post-mortems did not support the theories of atrophy, as the smaller organs appeared normal for the age of the patient.

Our thanks are due to Dr. Kenneth Smith, of Camberwell, for permission to show Case 1, and to Mr. O. L. Addison for Case 2.

OXFORD MEDICAL SOCIETY.

Treatment of Empyema.

At a meeting of this Society held last month at the Radcliffe Infirmary, the President, Dr. E. Mallam, being in the chair, Mr. F. J. Hathaway (Windsor) read a paper on this subject. He began by pointing out that the treatment of empyema—namely, incision and drainage by a tube—had not changed for the last 100 years. He hoped that soon the open drainage of a chest with a sucking wound would be looked on as a surgical abomination. The post-war surgeon was not satisfied with the eradication of disease or pus alone, but put before himself a higher ideal, namely, restoration of function, provided he ran no risk of septicæmia. In the case of the knee-joint, peritoneum, and pleura immediate closure of wounds had been more than justified by restoration of function.

As regards empyemata, Mr. Hathaway pointed out that the structure of the pleura was peculiar in that a rigid thorax was associated with a collapsible lung; in the treatment of empyema with collapsed lung, it was therefore essential that the lung should be encouraged to expand as fully and as early as possible, for it was not until the lung fully expanded that pleural suppuration would end. This full and early re-expansion of the lung could only be produced by immediate closure, because this method did away with the two great hindrances to lung expansion—namely, the effects of atmospheric pressure and secondary infection.

After quoting his own experience in gunshot wounds of the chest as surgeon to a casualty clearing station, he briefly reviewed the history of such wounds, pointing out that even in the thirteenth century Henri de Nondeville immediately closed the chest in order to avoid a "sucking wound." With the era of gunshot wounds proper, Felix Wurtz, in 1563, recommended that chest wounds should be closed, as also did Guthrie and Baron Larrey in the nineteenth century. During the American Civil War, the Franco-Prussian War, and the South African War there was no improvement till after the first year of the late war, when the era of immediate excision of gunshot wounds, introduced by Sir Henry Gray, of Aberdeen, led the way for the immediate closure of wounds of the chest, abdomen, and joints.

As an important point bearing on the treatment of empyemata Mr. Hathaway described the crippling effects on the lung of adhesions, even in a simple hæmothorax. Mr. James Berry had laid down as an axiom that "a good surgeon is one who knows when to use a drainage-tube and when to remove it." Mr. Hathaway went further in saying "a good surgeon is one who realises that restoration of function is more important than the use or abuse of a drainage-tube." The historical treatment of empyema by Hippocrates, Galen, and Lister was then outlined by the speaker, it being pointed out that Prof. Schede, of Hamburg, was the first to insist on the necessity for the whole hand to be introduced into the pleural cavity for the removal of clots and adhesions.

Mr. Hathaway then dealt with the method of immediate closure of pneumococcal empyemata. Early and complete restoration of lung function could only be satisfactorily accomplished by complete operation—i.e., by freeing the pleura of all adhesions. The three most important points in the technique of operation were:—

1. Bacteriological examination of pus after aspiration. He did not advocate the immediate closure in any but pneumococcal cases. In a mixed staphylococcal and pneumococcal infection, or in pure staphylococcal or pure streptococcal cases, he advocated the use of a "passage-tube," also called a rubber "dam," with closure of greater part of wound or use of Carrel-Dakin treatment.

2. Sufficiently large incision and resection of one, or section of two, ribs in order to allow the whole hand to be introduced into the pleural cavity, the object being to remove pus and fibrinous clots and especially the adhesions on the visceral pleura which would cripple lung expansion.

3. After operation, daily aspiration of the fluid, put into the chest, with an aspirating syringe between the lips of the wound. This was quite painless. The fluid used to fill up the pleural cavity was either a 2 per cent. suspension of iodoform in paraffin or more frequently flavine. Daily bacteriological examination of the aspirated fluid was carried out until the fluid became sterile, when the aspiration could be stopped.

Mr. Hathaway cited his own cases, nine since 1917; 11 cases lately done by Mr. P. H. Mitchiner at the Middlesex Hospital; and the better results claimed by Mr. R. T. Timberg at the Physico-therapeutic Department of St. Thomas's Hospital, as regards early lung expansion and freedom from scoliosis. He also quoted papers by Dr. J. A. Nixon[1] and Mr. J. A. Blake,[2] of New York, both of whom advocated immediate closure in suitable cases. Dr. Nixon, in fact, had stated his belief that the time would shortly come when open drainage of the chest would be looked on as a surgical abomination.

In conclusion, Mr. Hathaway claimed that the immediate closure of pneumococcal empyemata was now established, and that if the technique of early and complete operation were carried out the mutilating operation of Estlander would no longer be necessary later. Convalescence would be shortened and the physico-therapeutic results would be much better than they ever were with the use of a drainage-tube.

Discussion.

In the discussion which followed Dr. W. Collier spoke of the value of washing out the pleural cavity in cases which were not improving with ordinary drainage. Mr. H. A. B. Whitelocke emphasised the importance of the respiratory diaphragmatic movements in thoracic as well as in peritoneal drainage. Dr. A. G. Gibson, Dr. W. Stobie, and the President also took part.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Heart Disease in Pregnancy.

A meeting of this Society was held at Manchester on Dec. 15th, 1922, with Mr. Harold Clifford, the President, in the chair.

Mr. A. Leyland Robinson (Liverpool) read a paper on Heart Disease in Pregnancy and said that the conclusions formed by Angus Macdonald in 1878 were in the main surprisingly applicable at the present time, although some modifications had to be made in view of the results of recent cardiological research. The latter had shown that cardiac murmurs did not necessarily indicate serious disease and that many systolic bruits were innocent if not actually physiological. The myogenic theory of heart conductivity had been demonstrated and a rational explanation provided for many types of formerly obscure cardiac irregularity. The discovery of auricular fibrillation had brought to light an important mechanism in the production of heart failure. Prognosis was now determined by the efficiency of the heart muscle and its capacity for work. A pregnant woman with heart disease was primarily a heart case, but the influence of pregnancy on cardiac disease and the special dangers of labour formed a problem of great importance to the obstetrician.

Pregnancy affected the heart and circulation in several ways: (1) An increased output of blood was demanded by the growing tissues (uterus, breasts) and by the placental circulation; (2) the uterine tumour produced certain mechanical effects by simple pressure on the base of the lungs and on the heart itself which was dislocated upwards and rotated to the left; as a result the pulmonary circulation was impeded and the right heart embarrassed. Pregnancy, therefore—and in particular labour with its severe muscular

[1] Bristol Med.-Chir. Journal, 1921.
[2] Annals of Surgery, April, 1922.

effort—implied cardiac strain and called up the reserve power of the heart; in health that reserve was quite adequate, but in disease such physiological response might be impossible and heart failure would then occur.

Mr. Robinson referred to 39 cases from the Liverpool Maternity Hospital comprising 26 mitral stenosis, 6 mitral regurgitation, 2 aortic regurgitation, and 5 functional cardiac disease. Five of these patients died: four from mitral stenosis, and one from aortic regurgitation and mitral stenosis. The effect of treatment was shown by the result in 17 cases of mitral stenosis (10 with severe and 7 with advanced disease). Of 12 women who received careful pre-natal supervision, 1 died (a difficult breech delivery), and 5 women who received no such treatment all died. Accurate cardiological diagnosis was essential before undertaking treatment, as many systolic bruits and arrhythmias had no pathological significance and no treatment was required. In the presence of organic disease, rest and prolonged observation were of first importance; the physiological activities of the patient must be limited and made to conform with the capabilities of the heart muscle. The appearance of signs of incipient heart failure (such as the persistence of crepitations at the pulmonary bases) indicated that the cardiac reserve was being seriously encroached upon and demanded special treatment.

Drugs of the digitalis group were chiefly called for by auricular fibrillation, whilst hæmatinics, regulated exercise, and nourishing food were of great value in improving the tone of the cardiac muscle. The termination of pregnancy might be called for under special circumstances. In early pregnancy, for the incipient heart failure of aortic disease for compensation once broken could not be restored by treatment or for a progressive decompensation in mitral stenosis when there was no response to digitalis. In advanced pregnancy the induction of premature labour was permissible for mild cases with full compensation, but was definitely contra-indicated in the presence of heart failure near term. The conduct of labour was a great responsibility and required careful consideration. During delivery per vias naturales morphia was extremely helpful in reducing the voluntary efforts of the patient and forceps might be employed to expedite delivery.

Cæsarean section would give better results, particularly in the case of a primipara where (1) the disease was severe and the heart barely compensated and the reserve poor, or (2) if there was the least reason to suspect delay or difficulty in delivery. Although many cardiac patients successfully passed their one or more confinements and the immediate result appeared to be satisfactory, the strain on the heart was rarely transient, but usually prolonged and sometimes permanent and irremediable. Apart from parturition many cardiac diseases were naturally progressive, as endocarditis, which was prone to occur, might convert a quiescent lesion into an active and progressive one. It was, therefore, doubtful whether repeated pregnancies should be allowed, and if not, the question of sterilisation would have to be cautiously considered in those cases where it was not possible to prevent conception.

The paper was discussed by Dr. DOBBIN CRAWFORD (Liverpool), Prof. W. E. FOTHERGILL (Manchester), and Dr. J. E. GEMMELL (Liverpool).

MIDLAND MEDICAL SOCIETY.

THE fourth ordinary meeting of the session was held in the Medical Institute, Birmingham, on Dec. 20th, 1922, Dr. C. E. PURSLOW, the President, being in the chair, and about 40 members present.

Exhibition of Cases.

Mr. A. W. NUTHALL showed a father and two daughters, who exhibited the combination of blue sclerotics and multiple fractures. The father had over 30 fractures, and both daughters had fractured several bones. Mr. Nuthall reviewed the literature of this interesting condition. The cases were discussed by Dr. A. P. THOMSON, who knew of four families exhibiting the same symptoms. He stated that in these cases the fractures were frequent up to the age of 10 years, and later much less so.

Dr. J. G. EMANUEL showed a man of 52, who for some years had suffered from attacks of a rare form of paroxysmal tachycardia. In the attacks, which lasted from 2 to 3 hours up to 3 to 4 days, the pulse was slow, 34 per minute, consisting of runs of 2, 3, 4, or 5 regularly spaced beats at a rate of 82. These runs were separated by pauses of 3 to 7 seconds in which no beats could be felt at the wrist and no heart sounds were audible over the præcordium. The electrocardiogram showed that the silent pulse periods corresponded to paroxysms of ventricular extrasystoles arising in the right ventricle at the rate of 173 per minute, as many as 17 being counted in a single paroxysm. In the paroxysm the ventricle drove the auricle with a reversed heart-block of 2 : 1 and sometimes 3 : 1. During the intervals between the attacks the pulse was regular, at a rate of 60 to 66 per minute. A similar case was described in *Heart.*[1] These cases were clinical counterparts of the paroxysmal tachycardia experimentally produced by Sir Thomas Lewis by ligature of the right coronary artery.[2] Dr. Emanuel's case was discussed by Mr. W. H. BUNTING, Dr. K. D. WILKINSON, and Dr. G. H. MELSON.

Pasteurisation of Milk.

Dr. JOHN ROBERTSON, M.O.H., Birmingham, read a paper on the Pasteurisation of the Milk-supply in Birmingham, emphasising the following points: About 75 per cent. of the milk-supply in Birmingham was at present pasteurised or sterilised in order to prolong the life of the milk. Several firms sterilised milk in bottles. Milk should be efficiently pasteurised, then cooled to a temperature of 40° F., and bottled in a bottle which has been sterilised. Such milk was safer than any other variety of milk, pathogenic organisms—tubercle, enteric fever, scarlet fever, sepsis, &c.—being killed. No contamination could take place until after the bottle had been opened in the consumer's house. Probably less damage to vitamins was caused than by nursery heating. The keeping properties were better. Because the milk was clean, safe, and of good quality more milk was used. Dr. Robertson's paper was discussed by Dr. MELSON and Dr. J. J. ROBB.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A MEETING of this Society was held at the Royal Devon and Exeter Hospital on Dec. 21st, 1922, Dr. G. P. HAWKER, the President, being in the chair.

Dr. F. A. ROPER showed a boy, aged 11, whose condition pointed to deficiency of posterior lobe of pituitary gland (? Frohlich's syndrome). There was no history of injury during parturition or of prenatal infection. The boy weighed 14 lb. at birth, had steadily gained in weight, but had never been able to walk owing to an affection of the muscles not unlike that resulting from anterior poliomyelitis. The knee-jerks were absent, but other reflexes were normal and the hand grasp up to the average. There were no ocular symptoms and intellectually the boy was bright. The skin was thin and clear. Wassermann reaction had proved negative. The sugar tolerance was appreciably raised, an ingestion of 250 g. being possible without production of glycosuria. X ray showed the pituitary fossa to be normal or possibly smaller than normal.

The PRESIDENT showed a case of Optic Atrophy in a young woman. The disease was unilateral and the symptoms first showed themselves when the patient was recovering from double phegmasia alba dolens following childbirth. The condition appeared to have arisen from embolism of the central artery.

---

[1] Heart, 1912–13, iv., 128.
[2] Ibid., 1909–10, i., 98.

Mr. A. L. **Candler** showed a man with enlarged gland above the inner extremity of the left clavicle—probably malignant—the case being of interest in that there was no other evidence of recurrence after removal of the tongue for carcinoma in 1920. He mentioned the peculiarity of the lymphatic supply to the tongue which would account for the distant throw of the secondary growth.

Mr. **Candler** also showed:—

1. Ovarian Cyst removed from a nurse who gave a clear history of illnesses diagnosed as "appendix abscess" and "pelvic tumour with obstruction" eight and six years ago respectively. On each occasion the immediate operation advised was refused, but two months ago pelvic pain and dysmenorrhœa decided her to submit to exploration. The points of interest were: (*a*) Both ovaries were without pedicle and adherent to surrounding structures; (*b*) both contained dark red material not unlike motor grease at a summer temperature—there was no fluid; (*c*) history non-suggestive of ovarian cyst during past six years.

2. Fibroid of Uterus which had been extruded into the vagina, the lower part having become gangrenous and there being a thick intra-uterine pedicle. The cervix had been examined and found normal some four weeks prior to operation.

Dr. R. V. **Solly** showed microscopical sections illustrating a series of tumours of the breast.

Reviews and Notices of Books.

SCOTT'S ANTARCTIC EXPEDITION (1910–1913).

The Worst Journey in the World. By **Apsley Cherry-Garrard.** London: Constable and Co. 1922. Pp. 585. £3 3*s.*

The author of these volumes, which deal with Scott's last Antarctic Expedition (1910–1913), states in the introduction that the nine years' delay in the appearance of his book was caused partly by the war and partly by the effects of the expedition upon his physical condition. The intervening time is not a matter for regret, for it has enabled the author to bring together in his book an unbiassed survey of the hardships and work of the various sections of this expedition. The volumes tell the tale of what is known as "The Winter Journey," and make a special appeal to the medical reader, for they picture in vivid and stimulating terms the courage and endurance of the medical members of the party. The story is told of Dr. Murray Levick, who, stranded with Campbell's party at Evans's Coves, was forced to face the Arctic winter without sufficiency of clothing, food, or accommodation, and managed to carry on with the help of physical exercises and simple remedies; and of Surgeon-Commander E. L. Atkinson, in charge of the whole expedition while Scott was away, because Lieut. Evans was sick and on his way to England. The author referred to this command in these words: "The part fell to Atkinson, and I hope that these pages will show how difficult it was, and how well he tackled it"—indeed they do. Again, for the record of the indomitable spirit and scientific zeal of Dr. A. E. Wilson on a winter journey in search of the embryos of the Emperor Penguin, or on that last journey from which he never returned, we are indebted to the author of these volumes. His book is a monument to the influence of medicine upon such undertakings, from the first conception of the efficiency of the physical material, through the perplexing questions presented by apportioning Polar rations or dealing with such scourges as scurvy and dysentery, up to that final and paramount matter of the maintenance of "heart."

There are many stirring records of human endurance simply told. Dr. Levick referred to one incident as follows: "We started on our journey; this lay, first of all over quite half a mile of clear blue ice, swept by the unbroken wind, which met us almost straight in the face. We could never stand up, so we had to scramble the whole distance on all fours lying flat on our bellies. By the time we had reached the other side, we had had enough." On the winter journey Mr. Cherry-Garrard started away from the barrier with two or three blisters an inch long on each of his fingers; he eventually obtained relief only when he was able to thaw out, and then puncture, the blisters after supper! He gives a vivid picture of pain when he says, "to handle the cooking jar with the matter inside these big blisters frozen into ice or to touch the food bag was agony; to start the Primus was worse." In a temperature of from minus 60–77° Fahrenheit the description of the frozen clothes and sleeping bags must be read to appreciate the limits of endurance to which the human body can be put and still survive.

In the account of dysentery and scurvy and the means taken to mitigate these diseases, there is much of interest; frost-bite and minor ailments caused trouble, not least among these being cramp in legs and stomach. Campbell's party suffered chiefly from scurvy and ptomaine poisoning, while an interesting comment on dysentery is "they had some Cerebos salt, however, and used it for a week to stop the disorder." As to food, the following note is significant: "There were red-letter days, however, such as when Browning killed a seal, and in his stomach found, 'not too far digested to be still eatable,' 36 fish." One cannot help wishing, as one reads these pages, that the knowledge we possess to-day of vitamins, and of the influence of variety in food on the digestibility of meals, had been at the disposal of this expedition. The rations of the winter journey party consisted of—(Wilson) 8 oz. butter, 12 oz. pemmican, and 12 oz. biscuits; (Bowers) 16 oz. pemmican, 16 oz. biscuits; (Cherry-Garrard) 20 oz. biscuits, 12 oz. pemmican. Imagine this each and every day for six weeks! When we consider these rations it must increase our wonder and respect for those men who in the middle of an Antarctic winter went out on a six weeks' scientific expedition. The party started out on rations which they regarded as tests of fat, protein, and carbohydrate rations, in order to gain experience for the sake of those who were to make the supreme dash for the Pole the following summer.

The tale of the Scott expedition has been told from many sides, but the perspective shown in this latest account of it makes it an ever new and wonderful story.

GLYCOSURIA AND DIABETES.

Modern Methods in the Diagnosis and Treatment of Glycosuria and Diabetes. By **Hugh Maclean**, M.D., D.Sc., M.R.C.P. Lond., Professor of Medicine, University of London; Director of the Medical Clinic, St. Thomas's Hospital. London: Constable and Co., Ltd. 1922. Pp. 159. 12*s.*

This book is written on the same lines as that on "Renal Diseases" by the same author. The physiology of sugar metabolism, the types of the disease, the principles and details of treatment are all dealt with in turn. A good account is offered of the physiology of the disease, and the normal and abnormal variations in the blood-sugar after a dose of sugar. A description is given of the author's recognised method for estimating the sugar in the blood. Bertrand's method is employed for estimating the sugar in the urine, but although it may be very accurate is hardly suitable for the busy practitioner, and, indeed, this may be said of some of the other methods which are described, and which are more suitable for the laboratory worker.

The principles of modern treatment are given fully, and the quantities of the food advised for each day are clearly set out. The plan of treatment recommended closely resembles the original one devised by Allen. Allen[1] has now modified the treatment considerably by abandoning the preliminary testing of the carbohydrate tolerance with increasing quantities of vegetables. In Maclean's scheme this preliminary testing lasts seven days. A good table of caloric and sugar values is given.

There are certain points which need comment. In the title of the book the name of the disease is given as "Diabetes," presumably by an oversight, for no form of diabetes other than diabetes mellitus is dealt with. Although the author realises that aceto-acetic acid or diacetic acid is always present in the urine if acetone is present, he causes confusion on two occasions. Thus, on p. 88 he heads a paragraph Rothera's Test for Acetone, but promptly explains that the test is much more sensitive for diacetic acid than for acetone. But on p. 52 he says: "Acetone was present in five cases, while the urine of one of the patients contained diacetic acid as well." The value of the ferric chloride test in conjunction with Rothera's test is carefully explained. The author prefers to use Fehling's solution for testing the urine for sugar, and explains the cause of the doubtful reactions which are obtained. The absence of references (nine only are given) is unfortunate, for it might lead the reader to suppose that the author claimed priority for the observation that lævulose does not cause a rise in the blood-sugar, whereas this effect was described by Bergmark in 1914, seven years before Maclean and de Wesselow published their paper.

We have called attention to small defects in a very useful volume. The practitioner will appreciate particularly the section on Treatment, even if some of the laboratory tests are rather outside his scope.

Radiotherapy in Skin Diseases.

X Rays and Radium in the Treatment of Diseases of the Skin. By George M. MacKee, M.D., Assistant Professor of Dermatology and Syphilology, Columbia University. London: Henry Kimpton. 1922. Pp. 602. 45*s.*

The history of radiotherapy in diseases of the skin is very like that of vaccine therapy. As Dr. MacKee points out in a historical review at the beginning of his book, it may be divided into three eras—optimistic, pessimistic, and realistic. The initial wave of enthusiasm that followed the application of Rontgen's discovery to the treatment of disease by Schiff and Freund was to an extent checked when some of the earlier workers and their patients developed radiodermatitis from prolonged and frequent exposure, and Brown and Osgood demonstrated that the rays could produce sterility. Then followed attempts to measure both the quality and quantity of the X rays, and, as the result of the experiments of Sabouraud and Noiré, Holzknecht, Corbett and others, whereby reliable radiometers were perfected, these tragic accidents became less frequent, though their effect is still apparent in the reluctance of some patients to submit to X ray treatment. While comparatively rare nowadays, cases of permanent alopecia from overdosage in the treatment of tinea tonsurans still continue to occur, and it is not to be wondered at that parents occasionally refuse to allow their children to run the risk of such an irremediable disaster. In 1914 Coolidge produced his electron tube, which has proved to be far superior to the ordinary gas-tubes, and at the present time X ray therapy may be considered as a safe procedure in the hands of those who have mastered the technique and who are aware of the possible after-effects of injudicious dosage. Unfortunately, however, in this country at any rate, X ray treatment for diseases of the skin is sometimes undertaken by those who, although expert technicians, have no special knowledge of dermatology, and this is a practice to be condemned, since the dosage and number of applications required in a given case depend on dermatological knowledge and experience, without which even the most competent radiologist may go astray.

Dr. MacKee is not only a dermatologist of the first order, but he has devoted himself especially to radiotherapeutics, and his book is the product of an experience of radiotherapy in skin diseases probably second to none. The earlier chapters deal with the history and general physics of the X rays, the various types of apparatus and tubes, radiometry, and the technique of X ray and radium therapy. Then follow informing chapters on the chemical, biological, and biochemical effects of the X rays and radium, the clinical features of radiodermatitis, its treatment, its pathological histology (illustrated by excellent microphotographs), the action of radiation on pathological tissues, and general therapeutic considerations. The remainder of the book is devoted to a detailed consideration of the various diseases of the skin in which radiotherapy is indicated or has been tried, and not only are brief clinical descriptions given, but methods of treatment other than by radiation are also mentioned. It is pleasant to record that Dr. MacKee is in no way afflicted by radiomania, and he does not hesitate to state that radiotherapy is inadvisable in those diseases in which experience has shown it to be without effect, nor does he omit to mention his failures in conditions usually amenable to the X rays or radium. As an example of the author's wide experience, we may mention that he has treated 30 cases of mycosis fungoides with X rays and radium, and his conclusions coincide with those of most dermatologists—namely, that although radiotherapy usually prolongs life and gives relief in this disease it cannot be said to cure it. In the chapter on hypertrichosis, Dr. MacKee discusses in logical fashion the pros and cons of treatment by radiation, and gives the views of leading authorities both in America and other countries. The majority do not hesitate to condemn the method outright, owing to the risk of subsequent atrophy and telangiectasia of the skin; with this Dr. MacKee concurs, and he deals with the medico-legal aspects of the question, pointing out that "not even a signed, witnessed, and sworn statement, in which the patient states that she appreciates and accepts the risk," can prevent the institution of a suit for malpractice. A point of interest is that Dr. MacKee is not convinced that filtered rays are better than unfiltered for this treatment, in spite of the contrary opinion of those who still employ the method.

The book closes with an adequate statistical and descriptive account of the treatment of malignant new growths of the skin, and a chapter on the medico-legal relations of Rontgen and radium therapy. Throughout a large number of references are given at the end of the various chapters, and we consider that Dr. MacKee has, in writing this work, rendered a great service to dermatology and radiology.

Tuberculosis in Men and Animals.

L'Infection bacillaire et la tuberculose. Chez l'homme et chez les animaux. Second edition. By A. Calmette. Paris: Masson et Cie. 1922. Pp. 644. Fr.50.

The first edition of this book was exhausted a few weeks after its publication, and in preparing this, the second, edition the author has incorporated a separate chapter on chemotherapy. This chapter is a survey of recent research, and though it deals with a diversity of experiments, it is not very hopeful with regard to the future of this line of attack on the tubercle bacillus. In other respects this edition differs but little from its predecessor—a work of enormous dimensions. To attempt a comprehensive review would be like undertaking to make an inventory of the British Museum on a piece of notepaper. Had the author confined himself to an account of his own investigations, he could, no doubt, have filled a large volume. But this is just what he does not do. The book is, in fact, a most painstaking digest of every important piece of research ever carried out in tuberculosis. Naturally such a survey has to be greatly condensed if space is to be found for all that is important, and the author has taken the wise line of keeping strictly to facts, and the most logical deductions therefrom, without launching out into those top-heavy creations of the imagination, those ingenious theories which appeal to authors who may be thinkers but are not always observers.

---

[1] Jour. Amer. Med. Assoc. 1920, lxxiv., 571.

The book, then, being too large even for a bird's-eye survey of the whole, it is best to fall back on review by sample. Let us take Chapter V., for example. Here, in the space of 23 pages, an account is given of the toxins of the tubercle bacillus, of exo- and endo-toxins, and of the best known tuberculins. These number 20, and a short account is given of the manufacture, dosage, and peculiarities of each. Separate chapters are devoted to tubercle of the serous membranes, of the skin, the blood, and other tissues, and a whole chapter is given to the question of heredity, predisposition, and familial contagion. The second part of the book is chiefly concerned with experimental tuberculosis and the behaviour of the disease in animals. The third part deals with the defensive mechanism and with diagnosis. The fourth part concerns immunity, natural and acquired, and there is a long chapter on the problem of vaccination. This is, of course, not yet solved, and the author has little good to say of such ventures as those of Friedmann. But—and this is perhaps the most hopeful topic discussed—the author does anticipate as a practical and feasible proposition the ultimate suppression of tuberculosis as a fatal disease by a system of prophylactic inoculation. Without this means the problem would surely be insoluble, for, according to the author, every tuberculin-positive man and animal is sometimes a distributor of tubercle bacilli, and as the overwhelming majority of adult human beings give a positive reaction to tuberculin, there is no prospect of stamping out the disease merely by preventing infection. The book is beautifully illuminated by illustrations, many of which are coloured. They not only show a variety of morbid lesions, but they also show the various ways in which animals can best be inoculated. Only by personal demonstration, or by pictures, is it possible in a book to show at a glance how a guinea-pig, for example, should be held when tubercle bacilli are to be introduced into the stomach, subcutaneous tissues, and eye respectively.

It is a sad, but true, fact that first-class authorities sometimes write third-class books. Some first-class books are written by almost unknown authors. Here we have a first-class book by one of the admittedly greatest authorities in the world on tuberculosis, and it belongs to that small—very small—class of books about which editors write to their reviewers: "Please let us have this book back for the editorial library."

Manual of Operative Surgery.

Fifth edition. By H. J. Waring, M.B., B.S., F.R.C.S., Surgeon and Joint Lecturer in Surgery, St. Bartholomew's Hospital; Vice-Chancellor and Dean of the Faculty of Medicine, University of London. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1922. Pp. 829. 15*s.*

This well-known manual of operative surgery has been revised and shows many innovations, both in the text and illustrations. It is valuable as being the work and views of a surgeon of wide experience, who has stamped his personality on it. Thus, in the section on the œsophagus, the author describes very clearly the operation of inversion for an œsophageal diverticulum, an account of which does not appear in the usual text-books of surgery. He also recommends the suturing of ruptures of the spleen and has obviously had success in this procedure. He is a strong adherent of routine removal of the gall-bladder for gall-stones —a view to which all will not accede.

These examples show the progressive nature of Mr. Waring's work; yet this progressiveness is tempered by a conservatism elsewhere in the book. In the section on operations on the thyroid, for example, there is no mention of the extreme usefulness of intratracheal anæsthesia; again, laryngotomy is advised before excising the tongue, an operation which is quite unnecessary when the tracheal method of anæsthesia is used. There are a few other omissions, such as a description of the removal of the ulcer-bearing area of the stomach as practised by the Leeds school, the methods of blood transfusion, the removal of carcinoma of the rectum through the perineum with suture of the upper end of the gut, a permanent colostomy having been performed. It is true that the first of these operations is not yet firmly established, and to the last there are certain theoretical objections, but they would seem to deserve mention. The author recommends irrigation of the peritoneal cavity after suturing a perforated gastric ulcer, though many surgeons have abandoned this. We are relieved not to find gastro-jejunostomy advised as a routine after closing the perforation; indeed, the possibility of doing it at the same time is not brought forward.

Views change so rapidly in surgery that new methods will fall into disuse with increasing experience, whilst discarded methods are sometimes revived as being the better. A critical attitude in choosing and recommending operative procedures is most desirable in a writer of such a widely read text-book as this. The volume gives ample evidence that the author is not only endowed with this faculty, but has the courage, born of experience, to set forth only those methods which he has found to be followed by success. We predict that the fifth edition will be even more widely read than its predecessors.

The Life of Lord Moulton.

By H. Fletcher Moulton. With a Preface by the Earl of Birkenhead. London: Nisbet and Co. 1922. Pp. 287. 15*s.*

It has been stated that the late Lord Moulton's individual contribution to winning the war was as great as that of any living Englishman. The statement can now be verified in the competent biography which filial piety has compiled. The chapter on the Fight for Amatol is an epic of chemistry. It tells how a learned judge, temporarily transplanted from the House of Lords to the Ministry of Munitions, raised our output of high explosive from one ton to over a thousand tons a day. In thus satisfying the requirements of our armies and making substantial provision for our allies as well, Moulton was not handicapped by the supposed defects of the mere civil servant, the mere business man, or the mere professor. There was no red tape in his department, and he must have treasured the classic example which his biographer prints in full, a five-page extract from a Q.M.G. file on the rationing of certain rats required for use in poison gas factories.

Not every schoolboy prodigy fulfils the promise of youth. John Fletcher Moulton at the age of 16 headed all England in the Oxford and Cambridge Local Examination. He went on to be Senior Wrangler (with double the number of marks gained by his nearest rival), an advocate with almost a monopoly of the big technical cases, the first practising barrister to become a Fellow of the Royal Society, a Member of Parliament, a Lord Justice, and afterwards a Lord of Appeal, the first chairman of the Medical Research Council in 1912, and finally Director-General of Explosive Services during the war. The record speaks for itself. Had he given his whole attention to science, he might have made some notable contribution to knowledge. But the combination of law and science made an irresistible appeal to his gift of lucid exposition. His opening of a technical case about patents or trade-marks was that of an expert witness in wig and gown. Chancery judges told one another that in their courts Moulton generally gave the scientific evidence while the witnesses argued the law. This gift of exposition was not less conspicuous in politics. One of Sir Frank Lockwood's best House of Commons caricatures, made during the death duties debates in 1909, shows "Mr. Fletcher Moulton explaining the

Chancellor of the Exchequer's Budget to Sir William Harcourt."

He knew his limitations, refusing a brief for the defence of Mrs. Maybrick against a charge of murder based on allegations of arsenical poisoning, then not so familiar as now, on the ground that he had but little experience of work before a jury. His appointment to the Court of Appeal was not universally acceptable, but he soon silenced his critics. His judicial instinct was sure. He delivered many dissentient decisions, but the bar often found these justified on further appeal to the House of Lords. The legal profession will remember him for his judgments, which were lengthy but illuminating, the medical profession for his reasoned opposition to the anti-vivisectionists. The general public will remember him as the man who, in the cant phrase, "delivered the goods," and who beat the Germans in their own field of applied chemistry. Had the war lasted through 1919 the enemy would have been treated to their own medicine in the form of mustard-gas on a scale which they had never contemplated.

Lord Moulton's biography is well planned and welcome. It provokes neither controversy nor personalities. His memory will not be the less honoured by reason of the fact that, though his circle of legal, political, scientific, and social acquaintance was wide, he kept no diary.

PATHOLOGY, GENERAL AND SPECIAL.

For Students of Medicine. Fifth edition. By R. TANNER HEWLETT, M.D., F.R.C.P., D.P.H., Professor of Bacteriology in the University of London, &c. London: J. and A. Churchill. 1923. Pp. 531. 18*s.*

IN reviewing previous editions of this popular manual we pointed out that the subject of general pathology is less beset by rigid bounds than any other in the medical curriculum. And it is fortunate for the student that Prof. Hewlett takes as his standpoint very largely vital pathology and not the irremediable end-results of the dead-house. The author as pathologist does not lose sight of the author as physician. For the same reason the subject is in constant flux, and Prof. Hewlett has been at pains to incorporate, and not merely add, new matter in each successive issue. The present (fifth) edition has again been revised and in part rewritten. New sections on deficiency diseases, allergy, encephalitis lethargica, herpes, and blood-grouping have been added, and several excellent plates and figures have been introduced. It is, of course, impossible in a work of this size to deal adequately with all branches of pathology, and such sections as those dealing with difficult and controversial subjects, arterio-sclerosis, the endotheliomata, chronic nephritis, and the like, must necessarily suffer by condensation. Nevertheless, the author has managed to compress a vast amount of information in a small space, and loses no opportunity to refer to new and significant work. Within its limitations this book will be found a sure and safe guide to the study of pathology and may confidently be recommended to students.

MICROSCOPICAL EXAMINATION OF FOODS AND DRUGS.

Third edition. By HENRY G. GREENISH, F.I.C., F.L.S., Professor of Pharmaceutics to the Pharmaceutical Society of Great Britain. London: J. and A. Churchill. 1923. Pp. 386. 18*s.*

IN preparing the present edition of this standard work the author has restricted himself to a careful revision of the text and has not increased the size of the volume, lest a higher price might place the book beyond the reach of many for whom it is intended. Users of the book who are past the student stage will probably regret that space could not be found for some additional matter, for instance, a concise account of quantitative methods in microscopy. The book is invaluable to those engaged in the analysis of foods and drugs; the descriptions of methods of examination and microscopical appearances are clear, comprehensive, and accurate; there is a large number of clearly drawn illustrations which are especially useful in the identification of powders. The subjects include all the important vegetable drugs, such as belladonna, digitalis, cascara, and nux vomica, as well as others less frequently heard of. Besides a description of these and of the common foods, cereals, cocoa, and so forth, there is a useful account of hairs and textile fibres. A section on the materials used in adulterating foods and drugs is included, and also a general scheme for the examination of powders.

The book will retain its position as the standard for teaching and reference on a highly technical and difficult subject.

THE THOMAS VICARY LECTURE.

A Glimpse into the History of the Surgery of the Brain. Delivered before the Royal College of Surgeons of England on Dec. 8th, 1921, by Sir CHARLES BALLANCE, K.C.M.G., M.S. Lond. London: Macmillan and Co. 1922. Pp. 110. 10*s.* 6*d.*

FEW persons outside the medical and anthropological world know that the surgery of the brain, which has made such gigantic strides during the last 50 years, goes back in a primitive form to Neolithic times. The old and the new are for ever meeting, and what is practically Neolithic surgery is still practised by the Shawiyas and Arabs of the Aures district in Algeria, a district lying between Timgad and Biskra.[1] Sir Charles Ballance, whose Thomas Vicary lecture appeared in THE LANCET shortly after it was delivered,[2] traces the history of the surgery of the brain from Neolithic times down to to-day, and many will be glad to possess the lecture in book form.

STUDIES FROM THE ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH.

Reprints. Vol. XLII. 1922. Pp. 616.

THIS volume consists of reprints of articles which have already appeared in various journals, reporting on work carried out in the Rockefeller Institute or under its grants elsewhere. The articles, 57 in number, are grouped under the headings Pathology and Bacteriology, Biophysics, Physiology and Pharmacology, Chemistry, Experimental Surgery, General Physiology, the Hospital of the Rockefeller Institute, and Animal Pathology, and reference is further facilitated by excellent indexes to authors and subjects. A wide range of subjects is covered, and though the articles are not equal in merit there is ample material here to interest workers in many fields. For example, W. C. Stadie describes the construction of an oxygen chamber and its use in the treatment of the anoxæmia of pneumonia; he suggests that the severity of this condition is an expression of the degree of impairment of the respiratory surfaces of the lungs. Dr. H. Noguchi's paper on the venereal spirochætosis of rabbits is reprinted here, as are also the series of papers by Dr. E. Uhlenhuth on the effect of iodine and thyroiodine on the growth of salamander larvæ. In a paper on cytological nomenclature Dr. E. V. Cowdry draws attention to the absurd reduplication of names which has crept into cytological literature; he has collected no less than 41 synonyms of mitochondria and points out with justice that this orgy of word-making cannot fail to embarrass progress in this science. Dr. F. L. Gates describes a new macroscopic agglutination technique which appears to differ not at all in essentials from the technique described by Sir A. E. Wright many years ago and elaborated in numerous publications since; at any rate, if there be any differences they are not brought out by the author.

The multiplication of scientific journals makes such a publication as this extremely valuable, and it is disappointing, therefore, to find that the series of papers on experimental diabetes which have appeared in the new *Journal of Metabolic Research* are not reprinted but merely referred to.

Reports and Analytical Records.

STABILARSAN.

(BOOTS PURE DRUG COMPANY, LTD., NOTTINGHAM.)

STABILARSAN is a chemical compound of "606" with pure medicinal glucose, and is supplied in ampoules in liquid form ready for either intramuscular or intravenous injection. The preparation has had prolonged clinical trial at St. Thomas's Hospital and elsewhere, and the results have been good, vexatious immediate reactions or delayed toxic manifestations not being recorded. The toxicity of starbilarsan is, as a matter of fact, lower than that of other arsenobenzol preparations, but freedom from toxicity has clearly been attained without any prejudice to therapeutic activity. Ampoules containing doses ranging from 0·10 to 0·90 g. are supplied, and administration is made simple, the syringe being filled directly from the ampoule with no addition of distilled water. This is evidently a very valuable preparation.

ALLENBURYS DIABETIC FLOUR.

(ALLEN AND HANBURYS, LTD., 37, LOMBARD-STREET, E.C. 3.)

When analysed this preparation was found to have the following percentage composition: moisture (loss at 100° C.) 9·2, protein (casein and lactalbumin) 76, fat 0·7, residual mineral matter 6·5. The flour is entirely free from carbohydrates (milk-sugar and starch). The statement that it is a mixture of caseins and lactalbumin to which cream of tartar and bicarbonate of soda have been added as leavening agents is confirmed on analysis. The flour serves as a convenient basis for preparing palatable carbohydrate-free foods, and directions for making such foods are supplied with the product. The flour should be found useful in indicated cases. The casein in it is digested with ease, taking the place of other forms of protein in the diet, and the property of neutralising "acidity" being considerable, it can be employed in cases of dyspepsia arising from over-acidity.

"ALMATA."

(KEEN, ROBINSON AND CO., LTD. INCORPORATED WITH J. & J. COLMAN, LTD., LONDON.)

The Local Government Board in 1914 issued a valuable report (New Series 80) on the use of proprietary foods for infant feeding, their analysis and composition, and generally surveyed the position from a dietetic point of view. The various analyses showed that whilst some of the foods were prepared with a reasonably proper balance of the constituents, others consisted of starch (generally heated flour) to which sometimes cane or milk sugar had been added. Information, similar to that contained in the official report, accumulated with the increased knowledge concerning food values acquired during the war, and the important part played by vitamins is to-day reflected in the character of infants' and invalids' foods prepared by the more progressive manufacturers.

Almata is such; it is a carefully-thought-out attempt to provide a food which contains soluble carbohydrates, fat, protein, mineral constituents, and the vitamins A, B, and C in suitable proportions. When analysed the following results were obtained:—

Moisture..	1·5 %	Fibre	0·4 %
Mineral matter ..	2·32 %	Carbohydrates ..	61·7 %
Containing phosphates (P_2O_5) ..	0·66 %	Active amylase ..	Present.
Proteins	11·37 %	Reaction	Neutral to litmus.
Fat	23·1 %	Preservatives ..	Absent.

The carbohydrates, consisting of malto-dextrins, maltose, &c., are mostly soluble in water. Of the proteins 25 per cent. are already soluble, a further 55 per cent. are dissolved during peptic and pancreatic digestion, and 20 per cent. are insoluble. The protein is partly derived from eggs which contain the water-soluble B-vitamin. The fat, in which the majority of infants' foods show a deficiency, is derived from milk and egg, both of which are the source of the fat-soluble A-vitamin. The water-soluble C-vitamin is introduced in the form of fresh fruit juice.

The manufacturers have submitted to us the results of feeding experiments with Almata, carried out at one of the best-known physiological laboratories. In the case of rats the growth was normal and their general condition was good, and when the diet was continued with the offspring of these rats their growth was also normal, providing a practical test of the efficiency of the diet. Further, certain tests were carried out under medical supervision, in which the food was given to infants and mothers, and the results recorded are satisfactory. That the food is of constant composition and keeps well is shown by the following figures:—

—	Moisture per cent.	Protein per cent.	Reaction.	Active amylase.
Made 3 months ago	2·7	11·4	Neutral.	Present.
,, 2 ,, ,,	2·3	11·6	,,	,,
,, 1 month ,,	1·5	11·4	,,	,,

Almata has a pleasant flavour and is only slightly hygroscopic. The food may be given to infants from 1 month old upwards.

PAVON.

(SOCIETY OF CHEMICAL INDUSTRY IN BASLE. SOLE CONCESSIONAIRES: CLAYTON ANILINE CO., LTD., PHARMACEUTICAL DEPT., 68½, UPPER THAMES-STREET, E.C. 4.)

Pavon is described as a standardised opium preparation representing the total alkaloids of the drug; in other words it is opium from which the inert and inactive substances are removed. It contains 25 per cent. of morphine and from 20–21 per cent. of the secondary alkaloids. We have examined Pavon liquid (in 15 per cent. alcoholic solution) and find in each c.cm. of it 0·022 g. of total alkaloids, which confirms the manufacturer's figure of 0·020. Pavon is also supplied in tablets and in ampoules, each one of which contains 0·02 g. alkaloids. The prolonged administration of Pavon, it appears, does not cause nausea or constipation; this advantage is due probably to the relative amounts of morphine and secondary alkaloids in the preparations.

Another preparation is *Pavon-Scopolamine* contained in ampoules, each containing ⅓ gr. Pavon and 1/200 gr. of scopolamine hydrochloride.

Hemypnone, a "twilight-sleep" product, is made up in tablets, each containing diacetylmorphine diallylbarbiturate 0·005 g. and trichlor tertiary butyl alcohol 0·5 g. When analysed we found chlorine equivalent to 0·48 g. of trichlor tertiary butyl alcohol per tablet. It will be apparent that the combined morphine in such a preparation is not the only analgesic present, but is supplemented by the trichlor tertiary butyl alcohol, which splits up in the organism to its component parts, chloroform and acetone.

THE LATE DR. H. POOLE BERRY, O.B.E.—Dr. Harry Poole Berry, medical officer of health for the Grantham Urban District, who died on Dec. 20th, 1922, received his medical education at Guy's Hospital, becoming M.R.C.S. in 1882. In the following year he graduated M.B. in the University of London. In 1888 he took up his post at Grantham, where he was also school medical officer to the Borough Education Committee and for many years an honorary surgeon to the Grantham Hospital. At the time of his death he was chairman of the Kesteven Division of the British Medical Association. Dr. Berry held the rank of Major, R.A.M.C. (T.), and earned the Territorial Decoration and the Volunteer Long Service Medal; prior to the formation of the Territorial scheme he was attached to the 2nd Battalion of the Lincolnshire Regiment, and during the late war saw service in France with the 4th (Territorial) Battalion. On returning to England he took an active part in local Red Cross work, although he never altogether recovered from the strain imposed upon him by active service. His professional skill, sincerity, and kindly disposition were greatly esteemed by colleagues and patients alike. Dr. Berry was at one time a contributor to the columns of THE LANCET. He leaves a widow and one daughter.

THE LANCET.

LONDON: SATURDAY, JANUARY 6, 1923.

A CENTENNIAL YEAR.

During 1923 The Lancet will complete 100 years of its existence. The first number appeared on Sunday, the 5th of October, 1823, and contained a prefatory statement to the effect that the objects of the new journal would be, primarily, "to produce a work that would convey to the public and to distant practitioners, as well as to students in medicine and surgery, reports of the metropolitan hospital lectures"; and, secondly, "to give a correct description of all the important cases that may occur whether in England or on any part of the civilised continent." And as though this programme was not sufficiently inclusive, Thomas Wakley, the Founder, with the audacity of youth—he was 28 years of age—added to his intentions the following: "Our columns will not be restricted to medical intelligence, but, on the contrary, we shall be indefatigable in our exertions to render The Lancet a complete chronicle of current literature." Those with access to the first number of The Lancet in its original form may note with interest or amusement how far in the space of 36 small octavo pages it was attempted to keep the promises made.

The metropolitan hospital lecture selected for report was one delivered on the 1st of October, 1823, by Sir Astley Cooper, and it is a good example of chatty exhortation to a medical school, the students present being described by the Editor (it may be feared with an eye on possible subscribers) in these words:—"We never before witnessed so genteel a surgical class; the sight was most pleasing, for they all appeared gentlemen of cultured manners and good education." A leading article succeeded entitled "Politics," whose medical interest is exactly nil, but the editorial opinion of the younger Pitt as "an official coxcomb, regardless of everything but the gratification of his own senseless, remorseless, and petty ambition," indicates from what political sections of the public, whom he proposed to address equally with medical men, the Editor hoped to obtain support. Pitt, of course, had been dead some years, but his name was used as a point of rally against Radicalism. Some notes on the drama were followed by three carefully written clinical cases from Newcastle-on-Tyne, from Lynn in Norfolk, and from Bedford, indicating the design to excite the interest of widely separated centres. Then came a long quotation, under the heading Medical and Surgical Intelligence, from the columns of the *London Medical Repository*. In this excerpt Mr. Henry Earle, assistant surgeon to St. Bartholomew's Hospital, carries on a controversy with Sir Astley Cooper, as to whether fracture of the neck of the thigh-bone ever unites, and also as to whether Cooper had said that Earle was maintaining the contrary view in order to depreciate Guy's Hospital and its teaching—for Cooper, while lecturer at St. Thomas's Hospital, was surgeon to Guy's Hospital. From the journalistic point of view there was considerable sagacity in publishing in the first number of the new medical paper, and in the front pages, an address by the acknowledged leader of surgery, while reprinting, as a quotation, a very civil but candid reflection upon his judgment. This article struck that note of criticism without fear of persons which the original Wakley intended should be characteristic of his venture, and which involved him in a group of libel actions for some ten years, in most of which he won actual or moral verdicts. The offer to supply a "complete chronicle of current literature" was met by quoting from the *London Magazine* a letter by "Elia" to Robert Southey, whom the Editor of The Lancet described as a "sack-hunting hypocritical rhymer," thus expressing the opinion of the Radical party upon the Poet Laureate, who had renounced the Republican and Unitarian views of his youth, to appear as a defender of the Established Church. A short paragraph, which promised mysterious revelations concerning a clergyman, led to the editorial request for certain information concerning that person, with which the number closes. Having regard to the direction which those revelations afterwards took, we cannot be surprised that in the second number the Editor of The Lancet has changed his printer.

How far The Lancet, as it now appears, differs from the journal in its first decade might be made the subject of self-congratulation in obvious directions, none of which we propose to take; and, while we may, or may not, regret, we cannot apologise for the absence from our pages to-day of the gay scurrility which enabled Wakley to command from the beginning a large audience for his projects of reform in the medical profession. We are more than content to believe that in essential design—namely, the desire to promote the cause of medicine and the interests of its practitioners—we have remained the same paper throughout the hundred years. We publish in another column a letter from Sir John Tweedy, whose personal recollections of The Lancet go back to the day of its Jubilee; and a retrospect over our first fifty years, suggested by this letter, shows the manner in which the original policy expanded, the varying places in which it was justified, and the singleness of the essential design. The whole pattern of hospital training was altered during those fifty years in accordance with plans suggested or supported by writers in the editorial and correspondence columns of The Lancet, or endorsed by those writers, often in a forcible fashion. Nepotism at the principal hospitals withered under this treatment, and the strictures were not confined to the leaders of the profession, for persistent exposure of the imperfect training which many medical men received was a powerful assistance to the passage of the 1858 Act of Registration. While the intention to appeal to the public directly was abandoned quite early, the purpose of this intention—namely, to effect sanitary and social reforms—was carried out by close inquiry into manifest abuses. From the beginning the claims of quack medicines were subjected to the chemical analysis of the day, and, when these methods were directed to the detection of food adulteration, a movement was started which led to the important legislation which we now possess. The part played by The Lancet fifty years ago in the reform of workhouse infirmaries, and in the institution of Hospital Sunday, shows again the determination to prove the connexion between the public weal and the work of medicine. But we do not wish either to enumerate old exploits or recent developments and activities. It is more fitting that we should acknowledge a genuine feeling that nothing in those early days could have been done by this paper, as nothing can be done by us now, without the coöperation, intimate help, and valuable criticism of our public. One little blow of our own trumpet we permit ourselves—we do not believe that our readers would have supported us through an unbroken century if they had not found us serviceable.

◆

SYMPTOMATIC TREATMENT.

A SENIOR medical student not long ago achieved praise by the succinct tone of the following answer to an examination question: Ætiology—unknown; prognosis—doubtful; treatment—nil. He had indeed summed up with depressing accuracy many pages in many text-books recording unsuccessful attempts to elucidate the prime cause, the probable duration, and the proved cure of the rather uncommon condition named, and he deserved credit for a just résumé, which could have been an expression of nothing but industry, for without wide reading he would not have dared to assume that his answers were adequate. But in medical practice a less uncompromising attitude is necessary, while the problems presented by patients are not always of the concrete sort that can be so briefly dismissed. Assuming that this examinee had been asked to differentiate between possible causes of this condition, to mention points in history that might influence prognosis, and to recommend treatment in certain associated symptoms, he would have had much to say if he was really a well-informed person, and, especially under the third heading, he would have been placed somewhat in the position of the practitioner while arranging his replies. The practitioner may be unable to suspend operations until the most direct line of attack has been ascertained; he may have to advance somehow, if only by engaging hostile forces as and when these manifest themselves, and even when their immediate origins become clear the *causa causans* may remain obscure.

There is thus a difference in outlook and in responsibility between the research student and the practitioner, and undoubtedly this leads to difficulties in the professional training given at the medical schools. Some persons even contend that at the present day the training given bears but little relation to the daily work of the practitioner. A cogent answer to such criticism is that if the student in his early years is encouraged to think in terms of symptomatic treatment his ideals will never rise above this level. It is the duty of the teaching staff of a hospital to equip a practitioner with a just conception of the processes of disease as at present understood, and with a comprehensive, if somewhat dogmatic, knowledge of accepted therapeutics; and the standardised examinations of the universities and corporations should test the candidate on these points. He will then be found competent at diagnosing common ailments, medical and surgical, including some of the most important diseases and injuries, and he will be able from hospital training to estimate their urgency, and decide on their treatment. He may not, however, have close acquaintance with some of the things which are judged by the public as too trivial for hospital advice, and, alas, these will include the early manifestations of many important illnesses, and he will have had little opportunity for learning the reasons why he should vary therapeutic measures in many conditions which appear similar, or why he should adopt a particular course in a particular case. Only individual personal experience can make this side of his professional life easier, but where an individual patient is suffering from some serious disorder for which no specific remedy presents itself, it seems possible that he might get more help from his teachers and from medical literature than he receives at present. The impulse towards a more scientific conception of medicine has led to the dismissal of too many disorders in text-books with the curt advice to "treat the cause." But as "A Pathologist" acutely points out in our correspondence columns there is a kind of disease prevention—and a very important one at that—which has nothing to do with ultimate causes and which can be pursued with success in ignorance of them. Exact illustrations of this situation may be found in Dr. Fortescue Fox's address on the Breakdowns of Middle Life which is printed on p. 55. To-day it may be assumed as common knowledge that we must treat the cause when we see it, but if it is not manifest even after careful search, or if when found it is irremediable, much may still remain to be done by the medical practitioner.

A series of articles, contributed by invitation, will appear weekly in our columns, and will represent individual experience in the treatment of diverse medical and surgical conditions arising commonly or rarely in practice. Every practitioner is occasionally perplexed by patients who do not respond to the treatment he is accustomed to order, having found it successful in apparently analogous cases. Aural or vaginal discharge, subacute rheumatism, intestinal worms, neuralgia, sciatica, habitual constipation—all these are among the conditions which he may find intractable in patients of every class in life, and it is no reproach to him that he is not familiar with all the methods that have been adopted successfully for their relief, or certain which of these methods has the most direct applicability in a given case. Personal experience which would have stood him in good stead in five or six of the conditions we have enumerated may fail him in a seventh; his hospital training yields only generalities, while he knows that a new technique now holds the field; his text-books may be silent; and search through medical literature is laborious. To meet these circumstances, which our letter-bag shows to exist, we have asked the help of writers who enjoy peculiar opportunities for helping their colleagues.

◆

NEUROSYPHILIS AND ITS PREVENTION.

THE solution of the problems presented by neurosyphilis and its treatment, attacked though they have been from every side during the last decade, has not yet been attained. We have no specific technique for treatment at all comparable in certainty of result to various antitoxin methods for some of the other infections, nor, for that matter, are we absolutely sure of our organism, as far as neurosyphilis is concerned. In his instructive address on modern methods of diagnosis and treatment of syphilis of the nervous system, which will be found elsewhere in this issue of THE LANCET, Sir FREDERICK MOTT argues for the existence of two varieties of spirochæte implicated in syphilis, the dermatropic and the neurotropic respectively. Notwithstanding the authoritative position of this eminent neuropathologist, which must lead us to weigh seriously his contentions, the actuality of these two distinct varieties is as much denied as accepted, and the evidence is still conflicting. The discovery of different strains of meningococcus has turned out to be of prime therapeutic significance in respect of the successful treatment of cerebro-spinal fever; by comparison, the indefiniteness of our knowledge of the *Spirochæta pallida* is a hindrance in the way of progress. Even though the assumption is made of one variety only, we are greatly in the dark as to its life in the infected individual. How the disease may be transmitted from one person to another years after the former has passed what is ordinarily called the infective stage, and how the virus may on occasion remain quiescent for a quarter of a century or longer, to break out into pathogenic activity in the fullness of time, are questions beyond our answering. Thus therapeutic success is still delayed largely through ignorance of the biological characters of the organism with which we have to deal.

The fact, however, that an appreciable and sometimes a very long interval separates the original infection from late neurosyphilitic manifestations should in reality be taken as a blessing in disguise and an incentive to the prosecution of active treatment. Cases in which neurosyphilis makes its appearance within weeks or months of the date of the chancre are altogether exceptional. If, then, the risk has been run of the development of neurosyphilis, surely the plain duty of the individual and of his medical attendant is to ascertain whether the nervous system is involved or not, and this long before clinical symptoms and signs reveal the truth to the most superficial observer. Self-evident as this suggestion is, it is amazing to think how seldom it is acted on. At the disposal of the investigator are simple tests in blood and spinal fluid the import of which cannot be mistaken should they indicate failure on the part of the individual to eliminate the original virus. While perhaps less than 10 per cent. of syphilitics subsequently develop neurosyphilis, it should none the less be a paramount necessity for all who have contracted the disease to submit themselves to routine examination from the neurosyphilitic standpoint. Before the potential tabetic has his attention drawn to persistent "rheumatism" in his legs, before the potential paretic begins to act strangely or to show the faintest trace of dysarthria, there can be no possible doubt that serological and spinal-fluid tests would furnish precious information, and would serve to orient treatment in the appropriate direction. We associate ourselves entirely with the emphatic pronouncements of Colonel L. W. Harrison, who in the excellent address on the treatment of the disease to be found in this number of The Lancet once more urges on all concerned the imperative need of thorough treatment not merely in the first instance, but just as much when the only evidence of neurosyphilis is in positive bacteriological findings. Herein lies for the present our sole prophylaxis. We cannot inoculate against neurosyphilis, but, fortunately, we can detect meningeal and spinal-fluid reaction to the activity of the virus in the insouciant individual who has been assured by uninformed opinion that he is "cured" and can marry with safety.

The many ingenious methods devised in recent years for the treatment of established neurosyphilis scarcely represent more than belated efforts to combat an evil which should have been stamped out by intensive handling at a far earlier stage. Their multiplicity can only impress the thoughtful physician with their inefficacity. Doubtless the necessity for their employment will remain just so long as the candidates for neurosyphilis are beguiled into a false sense of security by the disappearance of their first clinical symptoms or by an ostrich-like policy of ignoring what they would rather not think about. It is admittedly difficult to persuade the man in apparently perfect health to undergo revision of his case from time to time. The facts, however, being as they are, the practitioner naturally wishes to know what is the best line to pursue in the treatment of neurosyphilis, and he can learn from a perusal of the two addresses already alluded to what those who are the masters of their subject advise. We confess finality is far indeed from being reached. In this connexion we should like to direct attention to the recently published volume[1] by Prof. Wilhelm Gennerich, of Kiel, on the causes and treatment of syphilis of the nervous system, a book rich in clinical information and deserving of an English edition. Prof. Gennerich is an enthusiastic advocate of what he calls the method of "double puncture" in the treatment of the severe forms of neurosyphilis. His technique is approximately as follows. By spinal puncture distant two or more spaces from the usual site some 20 c.cm. of cerebro-spinal fluid are allowed to flow into a sterilised burette, which is then closed; into another burette attached to the needle at the ordinary site the rest of the spinal fluid is allowed to drain, 50 c.cm., or it may be considerably more, being thus withdrawn. In the first or upper burette a particular dosage of neosalvarsan in suitable solution is then placed and mixed, and the whole of the burette contents permitted to run back by gravity into the theca; finally, some 35–50 c.cm. from the second or lower burette are similarly run back, the idea being that this latter replacement of spinal fluid propels the salvarsan-containing part towards the upper spinal cord and cerebrum. Prof. Gennerich claims for his technique superiority in results over all others. In not a few other respects his methods merit favourable consideration and are worthy of patient trial.

Some day unification of procedures will announce to the expectant physician that success has been attained and a specific cure devised. Until then we can hardly hope to escape from the necessity of "trying out" techniques as diverse as that outlined above and the Austrian one, to which Prof. A. Pilcz calls attention on p. 19, of utilising malaria-infected blood. Which, if any, of them all is likely to stand the test of time and pass the standard for percentage of cures it is at this stage impracticable to estimate.

HYGIENIC TRAVEL.

The amalgamation, which takes place this week, of an immense number of competing railroad managements into a few well-distributed groups has given rise to new prospects of efficiency. For ourselves we entertain the hope that travel may not only be rendered hygienic, but may increasingly become an object-lesson in the essentials of health to the travelling public. At the present time the sanitary conveniences of the large railway stations in London and the great cities, although they lack the charm of, say, Aberdeen or Basle, are nevertheless clean and efficient; but the water-closets and urinals of most suburban and rural stations are unclean and inefficient—in many cases stronger terms would be appropriate—while the facilities for women are penurious. Waiting-rooms, if not warmed, should at least be clean, and we may hope that a time will come when it will be possible for any adult traveller to wash his hands at a railway station and for any child to obtain a drink of clean water. Much, of course, depends on the coöperation of the travelling public, but railways have already done a great deal to discourage the ugly habit of expectoration; travelling manners are improving and the companies should maintain their lead. Our Roumanian correspondent tells us that the sanitary board of the State railways is setting up certain standards regarding ventilation and cleanliness in consultation with members of the medical profession. Perhaps the Royal Sanitary Institute or the Royal Institute of Public Health could initiate some rivalry among the railway directors in these matters, for undoubtedly hygienic travel might be made a valuable object-lesson.

Annotations.

"Ne quid nimis."

NEW YEAR HONOURS.

Five knighthoods for distinction in medicine make a good show in a list which records few political honours. Prof. David Drummond, who is pro-vice-chancellor of the University of Durham, presided with dignity at the Newcastle meeting of the British Medical Association last year. Dr. William H. Hamer, principal health officer to the County of London since 1912, has not allowed onerous routine duties to dull his zest for epidemiology or his initiative in fruitful hygienic research over an immense field. Dr. Bernard H. Spilsbury, during his tenure of office as senior pathologist to the Home Office, set a standard for expert evidence which contributed notably to the administration of justice. Dr. Norman Walker's wise guidance to the Scottish Board of Health, his assistance to medical recruiting during the difficult years of the war, and his recent service to medical education in India formed severally a strong claim to public recognition. Dr. George Cuscaden, of Melbourne, is honoured for his labours as Director-General of Australian Army Medical Services. In the Royal Victorian Order, Sir Milsom Rees, C.V.O., becomes K.C.V.O. In the Order of the Bath (Military Division), Surg. Rear-Admiral Jonathan Shand is appointed C.B., and Major-General Sir William Rice becomes K.C.B. In the Order of the Bath (Civil Division), a companionship falls to Dr. F. J. H. Coutts, a senior medical officer to the Ministry of Health. In the Colonial Office List, Dr. C. A. Wiggins, P.M.O. of Uganda Protectorate, becomes C.M.G., Dr. Henry Curwen (Zanzibar) and Dr. W. McN. Muat (Weihaiwei) become C.B.E., and Dr. Herbert Torrance (Palestine) O.B.E. Mr. H. P. Pickerill, L.D.S., also receives the C.B.E. for service in connexion with jaw operations on wounded soldiers in New Zealand. In the Order of the Indian Empire, the following appointments are announced:—K.C.I.E.: Major-General G. G. Giffard; C.I.E.: Lieut.-Colonel J. P. Cameron, Lieut.-Colonel Henry Ross, and Lieut.-Colonel Alfred Hooton. Sir Havelock Charles receives a knighthood in the Order of the Star of India. Kaisar-i-Hind medals are awarded to Dr. Robert Harper (American Baptist Mission, Burma), Dr. Isabel Carr (Leper Home, Hyderabad), and Dr. N. N. Parakh (Burma). Further appointments of O.B.E. (Military Division) are those of Major W. B. Purdon, R.A.M.C., and Major H. T. Stack, R.A.M.C. In fields nearly akin to medicine, a knighthood has been conferred upon Mr. Basil Clarke, Director of Public Education at the Ministry of Health, and a K.B.E. upon Prof. D. O. Masson, D.Sc., of Melbourne. Miss Helen Iles, acting matron of the New General Hospital at Bagdad, becomes M.B.E., and Sister Annie Blanche, of the Presidency General Hospital, Bengal, receives the Kaisar-i-Hind medal. To the recipients of all these well-deserved honours we offer sincere congratulation.

TOPICAL IMMUNISATION.

The teaching that in certain diseases susceptibility and immunity are characteristics not of the body as a whole, but of certain organs, is reviewed by Prof. A. Besredka of the Pasteur Institute in the *Paris Médical* for Dec. 2nd. This teaching is, of course, not wholly new. Its importance has, however, been greatly enhanced by recent observations which not only throw light on the processes of ordinary vaccination against small-pox, but also suggest new lines of research in such diseases as Mediterranean fever and other infections. The typhoid-dysentery-cholera group are examples of "organ receptivity." If, for example, Shiga's bacillus is injected into a rabbit's vein, and the animal succumbs to the infection, cultures from the blood, urine, and all the organs except the intestines will usually prove negative. The intestines, however, which usually contain a very mixed flora, are found to harbour only Shiga's bacillus. The same thing happens when Shiga's bacillus is injected subcutaneously, and if this bacillus is killed by heat or antiseptics, and then injected into a rabbit, the intestinal mucosa shows the turgescence and dilatation of its blood-vessels characteristic of infection with the living organism. The question naturally arises: Is the efficiency of vaccines prepared from bacilli of the Shiga group really due to the formation of antibodies and the like throughout the body? Is it not more probable that these vaccines create a local intestinal immunity by coming in direct contact with the organ for which they have a peculiar affinity? If this is so, why vaccinate the intestine by such a roundabout route as that entailed by hypodermic injection? In giving vaccines by the mouth, Prof. Besredka has found it necessary in the case of the typhoid-cholera group to give bile in advance, so as to render the intestinal mucosa sufficiently receptive. Vaccines from the Shiga group do not require such preliminary treatment. As antibodies are not demonstrable in animals immunised by the oral administration of vaccines belonging to the typhoid-dysentery-cholera group, it would seem that acquired immunity to the diseases of this group is a matter of local vaccination and nothing more. The theory of "organ receptivity" promises to provide a successful solution to the problem of vaccination against anthrax. In this disease the receptive organ appears to be the skin. If anthrax bacilli are introduced into the trachea, peritoneal or pleural cavities of a guinea-pig, it survives. But if its skin be but lightly infected the animal dies. When it dies after deep injection the skin has been contaminated in the process. Prof. Besredka has recently succeeded in rendering guinea-pigs immune to anthrax by anthrax vaccines introduced into the skin, and he hopes to prove that even the most susceptible mouse may have immunity conferred on it to certain diseases by cuti-inoculation. May not, Prof. Besredka asks, the success achieved by Sir Almroth Wright in the vaccine treatment of staphylococcal infections be due to cuti-inoculation? One result of this most interesting teaching must be that in the future we shall ask: Is such and such a disease characterised by "organ receptivity?" If it is, the next step is to get this receptive organ into as close contact as possible with the corresponding vaccine. Prof. Besredka suggests that, if his teachings are confirmed, intra-, not subcutaneous inoculation will be indicated in certain diseases.

UNDERWEIGHT AND OVERWEIGHT.

A recent statistical bulletin of the Metropolitan Life Insurance Company of New York sets out the experience gained by insurance companies in assessing the relation of body-weight to longevity. Overweight is generally admitted to be a serious impairment among insured lives, its gravity increasing in proportion to the excess in weight over the average for height and age. At the younger ages there is, however, a trifling exception, for then a limited amount of overweight is apparently an advantage; such young heavy persons have uniformly a lower death-rate from tuberculosis. After the age of 35 overweight, even in relatively small amount, begins to be dangerous. Among short men—that is, those below 5 ft. 7 in. in height, at the age-period of 40–44 years an excess of 20 per cent. in weight involves an added mortality of 30 per cent. above the normal. Turning now to the other side of the picture, under most conditions underweight is an advantage, except in early adult life among the taller men. To be over 5 ft. 10 in. high and 30 per cent. underweight brings 50 per cent. increased risk, but from the age of 40 onward underweight becomes a distinct advantage, and those who weigh between 10 and 20 per cent. below the average show the optimum condition of longevity. Average build, in truth, is not the best build, and statistical findings confirm the common observation that a large majority of our acquaintances who reach a ripe old age are of slight build. The

New York bulletin omits to mention two points to which great attention is paid in life insurance work in this country—namely, family precedents in respect of bulk and the relation of chest measurement to abdominal girth. It is almost a commonplace of insurance experience that large persons more often succumb at an earlier age to disease of heart or kidneys, to pneumonia, or to disorders which suggest the wearing out of machinery in the body. To discover a reason for this would be a fitting problem for the physiologist.

TRANSPLANTATION OF THE LIVING EYEBALL.

IN July last Dr. Koppanyi reported that he had been successful in transplanting living eyeballs in fishes and other lower vertebrates, and the Biological and Ophthalmological Societies of Vienna appointed a joint committee to study the problem thus raised. At a recent meeting of these two societies in the first Vienna eye-clinic reports were received on experiments conducted independently by several scientists. There was remarkable difference in the interpretation of these reports. Whilst the ophthalmologists stoutly denied that the experiments bore out the statements of Koppanyi, the physiologists and biologists present insisted on the possibility of successful transplantation. Dr. Quist, of the eye-clinic, stated that the eyes transplanted by him were soon subject to retrogressive metamorphoses: but he admitted that important structures, including the optic nerve and connective tissues, survived for months, although other parts of transplanted eyes lost their vitality completely. Prof. Przibram pointed out that in theory there was no reason why such transplanted eyes should not be made to function; re-union of a divided optic nerve was certainly nothing unexpected. Prof. Kolmer reported on a successful transplantation of an eye in a rabbit, but his confirmation of the experiments of Koppanyi was not regarded as convincing. Prof. Meller, director of the eye-clinic, considered the negative results of Quist's experiments to show the futility of Koppanyi's method, although it was pointed out with some force that any number of negative experiments could not deprive even a single positive result of its value.

IMPECUNIOUS STUDENTS ABROAD.

THE welfare of the student, especially of the medical student, is a matter of general concern. In many countries the difficulty of securing a sufficient number of medical students to supply the wants of the community is causing considerable anxiety. The cost of all commodities, and the difficulty of earning a living since the war, have compelled many parents to abandon the hope of giving their children a professional education. Others have made the attempt, but under such straitened circumstances that in not a few cases the health of the students has been injured for want of suitable food and lodging. It has recently been insisted, in a periodical entitled *l'Université de Paris*, that in France the measures taken to meet these difficulties are altogether insufficient. The cost of provisions and of rent has so increased that many students have abandoned all hope and left their universities. As matters now stand, a student in Paris must spend from 7000 to 8000 francs a year, which, according to the more recent fluctuations in the value of the franc, may mean anything from £114 to £160 a year. Though these figures apply to British students at Paris University the sacrifice is more considerable for French students in view of the depreciation of the franc. There exist, of course, various forms of assistance, such as coöperative restaurants where very cheap meals can be obtained; but a coöperative hostel with clean but cheap sleeping accommodation is even more necessary. Some students, to make ends meet, give lessons and get other work, but the strain of earning money and preparing for examination often proves too much, and their health breaks down. Others have won scholarships, which are, of course, of great assistance. In Belgium, Switzerland, and Czecho-Slovakia what is known as the *prêt d'honneur* is widely applied, and this system has become customary on an extensive scale in the Scandinavian States. It consists of a loan to the student which he cannot legally be forced to repay, and is not expected to repay unless he succeeds in passing his examinations, and, armed with his diploma, is able to earn his living. Then, solely as a matter of honour, he is expected to refund the money lent to him; it is gratifying to know that in most cases the money is repaid. As might be expected, the money comes from different sources. In Belgium a law, dated Nov. 11th, 1921, allows each province to create a fund for the assistance of students, and the Labour University of Charleroi has a special fund of its own for the purpose of granting such loans of honour. Then many voluntary subscriptions have been organised, prominent among them being the British Relief Fund, raised during the war, from which the University of Brussels derived very great benefit. The Swiss universities of Neuchâtel, Berne, and Zurich have loans of honour funds maintained by private subscriptions; in Czecho-Slovakia, as in Belgium, local authorities are authorised to raise the necessary funds, and the system has now worked very well for four years. In the Scandinavian countries considerable sums have been lent in this way, and no interest is charged. On the other hand, one or more signatures are required from persons of good repute who are willing to vouch for the student's good character. In France, a clause in the Budget of Dec. 31st, 1921, authorises the principle of loans of honour, but gives no details as to how the principle is to be applied. Still, for some years such loans have been granted on a small scale, notably at the École Centrale in Paris. The repayments are made so regularly that there are no complaints. It must, of course, be understood that such loans can only be made to promising students, the basic principle being that it would be a public loss if their studies could not be concluded. As a country has everything to gain from helping those who are likely to render valuable public service, a call can be made upon public funds for contributions towards the comparatively small expense involved. These considerations apply more especially to countries in which medical students are falling off in numbers, while their future services are indispensable.

"GENTLING" AND THYROID OPERATIONS.

PATIENTS with hyperthyroidism are generally in a fuss, and Prof. Crile has shown how the notorious dangers of thyroid operations in exophthalmic goitre may be minimised by careful psychical preparation of the patient. By getting the patient used to hospital and the paraphernalia of white coats and instruments, by daily practice with an anæsthetic mask, and so forth, Prof. Crile and his colleagues in Cleveland have reduced the mortality of thyroidectomy to about 1 per cent. in some 2000 cases. It is interesting to see that Dr. F. S. Hammett [1] in Philadelphia has quite independently come across the same phenomenon in rats. Studying the fatal incidence of acute tetany after the removal of the parathyroids, he found curious variations in the results, which were traced to the fact that the operated animals had come from two separate groups of rats. In one of these the animals had been petted and gentled and were continually in contact with human beings; they were not easily frightened, gave a uniform picture of placidity and had a mortality after parathyroidectomy of 13 per cent. The other group had had no more attention than is involved in ordinary cleaning and feeding; they were timid, apprehensive, and highly strung, gave a picture of constant high irritability, and had a mortality of 79 per cent. A third series of animals bred from wild brown rats were untamed, excitable, and pugnacious, and 90 per cent. of them died. Of the facts there is less doubt than about their interpretation. Dr. Hammett supposes that the more excitable animal has higher neural and muscular tension, greater instability, larger production of toxic by-products (possibly of the nature of methyl-guanidine and connected with creatine) and hence a greater need for the parathyroids to avert disturbances arising from these sources. But even if this is not the explanation, it is evident that "gentling" is an experience which would do many people good.

---

OPERATIONS AND THE PATIENT'S CONSENT.

Instances in which a conscious patient undergoes an operation to which he has not consented are so rare that the following case is of interest as well as of legal importance to the medical profession. In the *South African Medical Record* of Nov. 25th is reported a case heard in the Cape Provincial Division of the Supreme Court before Mr. Justice Watermeyer and a jury, in which £10,000 damages were claimed from Dr. C. C. Elliott, a well-known Cape Town surgeon, for amputation of the penis without the consent of the patient, and, alternatively, for performing an unnecessary operation. The plaintiff, a man aged 50 years, was admitted to the New Somerset Hospital, Cape Town, suffering from gangrenous ulcer of the penis. After a careful examination by the defendant, who is visiting surgeon to the hospital, and by Prof. G. B. Bartlett, of the University of Cape Town, who is pathologist to the hospital, it was decided that the patient was suffering from cancer and that to save his life the penis should be amputated. This was done, but the plaintiff stated that he consented to operation only under the idea that a circumcision was to be performed. He saw a report in which Prof. Bartlett recommended that the growth should be treated as "malignant," but he did not know what this meant. Some medical evidence was given for the plaintiff throwing doubt on the diagnosis of cancer and suggesting that, in any case, radium or X rays should have been tried before proceeding to amputation. Dr. Elliott in his evidence stated that he had had a good many similar cases, and had given this one much thought and research, looking up authorities. In his opinion, X ray or radium treatment would have been not only inefficient but dangerous. It was the duty of the house surgeon to obtain the consent of the patient, and he assumed that this had been done. The only responsibility he took was with regard to the operation. He took none with regard to obtaining consent, which was an administrative matter. The house surgeon explained that, as the patient was transferred from one ward to another in preparation for operation, he unfortunately assumed that his consent had been obtained. Prof. C. F. M. Saint gave evidence that, on Prof. Bartlett's report, amputation was the proper treatment. Since this case the hospital had adopted a printed form which must in all cases be signed by a patient giving consent before an operation. In summing up the judge said that a man did not waive control over his body by going into hospital, and that consent for operations should always be obtained, as admitted by the defence. In this case it was not obtained by an oversight, and the question arose, who was responsible? It was clear that no moral responsibility attached to Dr. Elliott, who was justified in assuming that consent had been obtained. But that did not affect the legal position, for if an assault had been committed, it did not matter whose duty it was to have asked for consent condoning that assault, everybody concerned being equally liable. When it came to damages the jury would have to consider, first, whether the patient was suffering from cancer; next, was the operation necessary to save life? If these two questions were answered in the affirmative, they would have to consider whether the patient had suffered any damage at all. The jury, by a majority of six to three, returned a verdict for the defendant, for whom judgment was given with costs. We congratulate Dr. Elliott on the result, but the case has an important moral. The surgeon should always make sure that consent for an operation has been secured.

A CHILDREN'S BENEFACTOR.

A national and representative committee is arranging to celebrate Sir William Purdie Treloar's eightieth birthday, which occurs on Jan. 13th. Treloar entered the paternal carpet business on Ludgate Hill at 15 years of age, became foreman in the Southwark factory, and travelled for the firm. He was elected to the Court of Common Council in 1881, joined the Court of City Aldermen in 1892, was a Sheriff of London in 1899, Lord Mayor in 1906–7, and is now the Father of the City Corporation. He was known as the "Children's Lord Mayor," for he gave as his sole reason for accepting the mayoralty his wish to help London children. In 1893 he began by sending hampers at Christmas time to small cripples, and now 5000 of such hampers are distributed annually. Realising that nine-tenths of the crippledom of this country is caused by tuberculosis, engendered by bad air, bad food, and the terrible surroundings of London slums, he vowed to establish a hospital for tuberculous crippled children and determined to collect for the purpose £60,000 during his mayoral year. In this he was successful, the City Corporation itself giving £1000 to the foundation. The Princess Louise Hospital at Alton, no longer required for the treatment of soldiers wounded in the South African War, was made over to Treloar and other trustees by special Act of Parliament. Treloar paid visits of inspection to Berck-sur-Mer and to the hospitals at Charlottenberg, and on Sept. 7th, 1908, the first patient arrived at the Lord Mayor Treloar Cripples' Hospital and College. Since then 2400 children have passed through the wards cured, and more than 300 older lads have completed a three years' course of training in boot-making, leather-work, or tailoring. A new seaside branch has now been founded at Sandy Point on Hayling Island, where the child's metabolism can be raised if necessary to ten times its normal intensity. Treloar's ambition to keep abreast of modern discovery in the treatment of surgical tuberculosis has been fully realised, and Alton methods have become the model for similar treatment elsewhere. Alton is, in fact, the realisation of the dreams of an alderman on Ludgate Hill and will be an abiding monument to him. The Earl of Balfour is chairman of the Tribute Committee, of which the hon. secretary is Mr. Percy Armytage, C.V.O., 33–34, Mansion House Chambers, London, E.C. 4.

STUDIES IN ETHER ANÆSTHESIA.

An essay, showing signs of prolonged and careful research, has recently been published by Dr. Karl Gramén,[1] of Stockholm, and his work deals with about 700 quantitative analyses of ether in the expired air and in the tissues of persons undergoing ether anæsthesia. He has come to certain practical conclusions with regard to the best methods for counteracting the effects of this anæsthetic, and while some of his conclusions may be regarded as unorthodox, others are confirmatory of reforms which have already been introduced by certain anæsthetists. Using a modification of the bichromate test for the quantitative analysis of ether in the tissues, he found that in the course of 10 to 12 minutes the ether content of the blood rises to about 80 mg. per cent., and remains at this level with only slight variations during the rest of the narcosis. After its completion the ether content of the venous blood falls rapidly during the first

---

[1] Untersuchungen über den Aethergehalt in Blut, Milch, Harn und Expirationsluft bei chirurgischer Aethernarkose sowie über Narkoseazidose. Supplement to Acta Chirurgica Scandinavica, 1922, lv., pp. 146.

15 minutes, in the course of which it is reduced by nearly 50 per cent. The elimination of the ether proceeds more and more slowly, taking one to two days. While the patient's age and health do not affect this process, its rate varies directly with the duration of the narcosis. It has been customary to interdict suckling for a considerable time after a nursing woman has been operated on for fear of the ether in her milk proving injurious to the infant. The result of this practice is that the supply of milk is often permanently reduced, and though Dr. Gramén's investigations show that the ether content of the milk is approximately that of the blood, he has come to the conclusion that an infant may safely be put to the breast two hours after the completion of narcosis. Of special and personal interest to anæsthetists is his observation that after the completion of a narcosis of average duration, the air expired by the anæsthetist during two minutes contains one drop of ether. With only one exception an increase of β-oxybutyric acid in the blood during narcosis was found, and among non-diabetic patients ketonuria was found in 9·9 per cent. before narcosis and in 67·7 per cent. after it. Ether evidently induces achylia, and of 21 samples vomited during narcosis as many as 15 gave a negative HCl reaction, which was faint in the remaining six. All the 12 samples vomited after the narcosis gave a negative HCl reaction. To counteract this condition Dr. Gramén recommends the administration of lemon juice or 10 drops of HCl to a tumbler of water. He is opposed to the old practice of pre-operative purgation, and instead of draining the body of its fluids he flushes it with water a few hours before the operation. Glucose and normal saline enemas may, in certain cases, be no better than a plain water enema, for glucose may provoke excessive fermentation and colic, and in cases of renal insufficiency the absorbed saline solution may embarrass the action of the kidneys.

THE INFECTIVITY OF WHOOPING-COUGH.

THE period during which a child suffering from whooping-cough is a source of danger to others, and the possibility of the occurrence of carriers of the infection, are questions of great practical importance in home and school hygiene. The usual working rule is to isolate a case of whooping-cough for six weeks or even longer if the whoop persists, but it is possible that close adherence to this rule may involve unnecessary economic loss. It has been suggested from time to time that the infectivity of whooping-cough is at its maximum during the initial catarrhal stage when the nature of the malady is at most suspected, and that when the characteristic whoop has developed the child, although usually strictly isolated, is then no longer a source of danger to others, at any rate after the second or third week. The occurrence of mild and atypical forms in which the whoop never develops, increases the difficulty of tracing the source of infection in a household or school. Fresh evidence on these matters is offered in a recent article by MM. H. Barbier and Renard in the *Bulletins et Mémoires de la Société Médicale des Hôpitaux de Paris* (Dec. 7th, 1922). These authors relate how they obtained the Bordet-Gengou bacillus in pure culture from the brother of a fully developed case of whooping-cough. In this instance the boy from whom the bacilli were obtained had nothing but a cough, whereas no bacilli could be isolated from the recognised sufferer from the disease. The bacillus was detected by means of making the suspect cough upon a medium of glycerinated potato contained in a Petri dish; and, further, the contact who was thus disseminating Bordet-Gengou bacilli did not develop a whoop. Similar instances may be met with in adults, and as an example there is quoted in the same article the experience of Delcourt at a school in Brussels, where it was found that one of the mistresses, who had a persistent cough, gave a positive complement-fixation test for whooping-cough, and presumably accounted for the continuance of the disease in the school. In accordance with these views children in Denmark who have had whooping-cough are allowed to return to school four weeks after the whoop has commenced, even if it still persists. Whooping-cough is one of the most fatal of infectious diseases for infants, and any means which may lead to the checking of the spread of an epidemic or to the detection of its source is worthy of serious consideration. At this season of the year children's parties are no doubt responsible in part for the dissemination of infectious disease, and the possibility that apparently unaffected contacts may themselves be infectious is a practical point which should be borne in mind by the school and family practitioner.

STATE AID FOR TUBERCLE IN SWITZERLAND.

THE Swiss Federal Council reported last month on the distribution of the sum of one million francs (about £45,000) which it had been authorised to spend during the year 1922 for the care of tuberculous patients. The expenditure took the form of subventions to hospitals, dispensaries, sanatoria, and open-air schools, the amount never exceeding a quarter of the total outlay of these institutions. Set out in tabular form the distribution was as follows :—

Institution.	Sums from private sources.	State aid.
	Frs.	Frs.
67 local dispensaries	1,625,000	469,000
38 sanatoria for adults	4,480,000	341,000
18 sanatoria for children	815,000	96,000
8 day schools in or near forests ..	105,000	12,000
47 private hospitals with wards for tuberculous patients	1,000,000	74,000
Total	8,025,000	992,000

A special Federal law is now being drafted to combat tuberculosis on a larger scale. This will be presented by the Federal Council to the Assembly in the course of the present year.

VACCINATION IN MADRAS.

THE dissatisfaction felt by the Government of Madras with the manner in which vaccination is organised and carried out in the city of Madras, indicated in the Indian letter which appeared in our issue of Nov. 18th, 1922,[1] is again expressed in the Madras Vaccination Report for 1921–22. In the course of their order recording the report, the Government observe that the salient factor of the year's record is the rise in the rate of success in primary vaccination, on account of (*a*) the cessation of routine examination during the months of hot weather, and (*b*) the improved potency of the lymph supplied. The Director of Public Health to the Presidency has called attention to the relation between the incidence of small-pox and the number of vaccinations affected. Whenever an epidemic breaks out, vaccination booms. The disease subsides, apathy supervenes, vaccination is neglected, the number of unprotected persons increases, and in four or five years the population is ripe for another epidemic. Towards the end of the year under review Madras was visited by one of the worst epidemics of small-pox ever experienced in the city. During the same period vaccination has nowhere kept pace with the "available" birth-rate; the qualifying adjective calls to mind the fact that in the report of the Director of Public Health issued in June, 1922, the opinion was strongly expressed that the whole registration of vital statistics was worse done in Madras than in any province in India, although in fairness it should be added that the census officer's conclusion was not equally condemnatory. The tone of the Government Order relating to the vaccination report is one of disappointment with the work of local bodies. The indifference of these bodies to vaccination is only too evident from an analysis of the report. No less than 60 out of the 80 municipalities showed a deterioration of work as compared with the previous year. The Director of Public Health gives two reasons for this discreditable performance. "It will be impossible to improve the personnel of vaccinators," he says, "unless local bodies make up their minds to pay them adequately or to give them at least a living wage." There is no dearth of candidates, but "the low pay offered makes the posts unacceptable to any but the incompetent." In the second place, the Revenue authorities and the magistracy should realise their responsibility and show a more sympathetic attitude towards the vaccination staff. It is ridiculous, for instance, that an armed Mahommedan should be able to assault a vaccinator in the discharge of his duties and then be let off with a fine of Rs.25. As the Government Order says, "it is useless for the King Institute and the vaccination staff to do their best in what is after all a mission guaranteeing the safety of the entire Presidency, if local bodies themselves refuse to profit by the labour and guidance of these authorities."

COMMON ERRORS OF DIAGNOSIS IN ACUTE INFECTIOUS DISEASES.

In the instructive series in course of publication under the editorship of Prof. J. Schwalbe of Berlin on diagnostic and therapeutical errors and their prevention, a special volume[1] has recently appeared on acute infectious diseases in childhood written by Dr. H. Kleinschmidt, director of the Hamburg University Children's Clinic. The diseases discussed are the commoner infections, which are classified in four main groups, according as the respiratory organs (pertussis, influenza, diphtheria), alimentary canal (enteric, dysentery, mumps), or nervous system (tetanus, cerebro-spinal fever, Heine-Medin's disease) are chiefly affected, the fourth group consisting of the acute exanthemata. In his introduction Dr. Kleinschmidt emphasises the fact that with the onset of an acute infection children are very liable to develop gastro-intestinal symptoms, so that the occurrence of vomiting, refusal of food, and, especially in young children, diarrhœa may lead to a mistaken diagnosis of gastro-intestinal catarrh. A careful examination of the whole body should therefore be carried out before such a diagnosis is made. In particular, inspection of the throat and testing the urine should never be omitted. The conditions most likely to be mistaken for pertussis are simple catarrh in a spasmophilic child, and spasmodic cough due to glandular tuberculosis or epidemic influenza. On the other hand, abortive or atypical cases of pertussis, which are apt to occur in the first months of life, often fail to be recognised. One frequently finds in family practice that the mother or servant is the first to develop an attack and to infect the children. The diagnosis of influenza, Dr. Kleinschmidt remarks, is only too readily used as a cloak for the practitioner's uncertainty of diagnosis. The principal diseases which must first be excluded are tuberculosis, typhoid fever, and acute leukæmia. The frequent occurrence of morbilliform and especially scarlatiniform rashes in influenza may also be misleading. While admitting that errors of diagnosis in diphtheria are sometimes inevitable, owing to the atypical character of the attack or unusual localisation of the process, Dr. Kleinschmidt maintains that they are most frequently due to failing to examine the throat. It is through such a sin of omission that many cases of diphtheria are at first treated as mumps —a point, curiously enough, not mentioned by the writer—and it is not until an advanced stage, when antitoxin is powerless to arrest the disease, that its true nature is recognised. At no age is enteric fever so likely to be overlooked as in infancy, when, owing to the irregular and often remittent type of fever and the absence of pea-soup stools it is liable to be mistaken for a febrile intestinal catarrh. It is therefore advisable to make a bacteriological examination of the blood in every febrile disease in infancy which does not show the characteristic features of alimentary intoxication or meningitis. In discussing the diagnosis of scarlet fever Dr. Kleinschmidt again insists on examination of the whole of the body, for it is through neglect of this simple precaution that numerous errors of diagnosis have been committed, special attention being paid to the inner side of the thighs, Scarpa's triangle, and the inner side of the upper arms. In rudimentary cases of scarlet fever these sites alone may be affected, and it is therefore not sufficient to examine the chest only for the presence of a rash. In the section on measles the writer emphasises the importance of examining the mouth in every febrile disease of children, for the presence of Koplik's spots, as well as for the measles enanthem, which consists of irregular, dark-red patches on the soft and hard palate. The difficulties of diagnosing non-eruptive measles, of which an example was recorded in The Lancet many years ago by Dr. J. D. Rolleston,[2] are also discussed. Like most physicians, with an extensive knowledge of the acute exanthemata, Dr. Kleinschmidt does not believe in the existence of the fourth disease, as described by Filatow and Dukes. On the other hand, he maintains that erythema infectiosum, which is apparently unknown except in German-speaking countries, is more deserving this title. In dealing with erysipelas, Dr. Kleinschmidt draws attention to the frequency with which beginners mistake the erythematous zone which normally appears round the vaccine vesicles between the seventh and eighth days for erysipelas—an error particularly to be avoided at the present time when vaccination is being performed on an extensive scale in this country. In the section on Heine-Medin's disease Dr. Kleinschmidt draws attention to the occurrence of rashes in the prodromal stage, and points out that the former belief that acute anterior poliomyelitis was a frequent sequel of measles or scarlet fever has been abandoned in favour of the view that scarlatiniform or morbilliform eruptions may be associated with infantile paralysis.

PRIMITIVE BACTERIOLOGY.

It is debated whether the ancient Hindus or the Chinese were the first to excogitate from their inner consciousness the existence of bacteria. There is no claim, we believe, for any earlier guess-work. In the Vedantic writings there exist representations of germs or microbes, and these at some remote date were copied into the Batak manuscripts of Java. The pictures in these manuscripts, which may be seen in some Oriental libraries, are painted upon bark and resemble the dashes, dots, loops, and twists of a large and loosely written shorthand. The dates of the MSS. and their Vedantic source must be very ancient, but no exact evidence on the point is forthcoming. More definite is the news from the China of the period of the Anglo-Saxon Heptarchy, which now comes to us in the pages of "Myths and Legends of China," the author of which, Mr. Chalmers Werner, of Pekin, is one of the most learned of living Sinologists. This fine work, published in the course of last year by Harrap and Co., contains a very interesting section entitled Myths of Epidemics, in which we have an illustration representing "the plague-disseminating umbrellas." These umbrellas, which are of the familiar Chinese kind, are being floated into the air by Lü Yüeh, President of the Ministry of Epidemics, and in private life an old Taoist hermit. He stands on the wall of a fortress, a bearded figure, for in these antique Chinese illustrations most of the male personages are bearded, robust, and resembling facially the hairy Ainus of Japan. His pleasant purpose in floating the plague-disseminating umbrellas into the air is to infect the mythic hero Yang Jên, who has deeply offended him in his official capacity as minister of health. "But the latter (Yang Jên)," says Mr. Chalmers Werner, "simply by waving his fan, reduced all the umbrellas to dust, and also burned the fort, and with it Lü Yüeh." The picture represents Yang Jên waving his fan, while clouds of large comma-like or horseshoe-like objects float from the umbrellas towards him. We dare not suppose that the Chinese knew the microscope or the magnifying glass, though so many modern Western inventions in some form or other had been forestalled by their ingenuity. The microbes, as figured, none the less are singularly like certain bacteria as seen under the microscope. In the China of this date five Gods of Epidemics were believed to exist, while the chief God of Medicine, Fu Hsi, was a mythical king. He had six hands, in which he held plague germs, the plague flag, and the plague sword. His date is given as about the year 599 A.D.,[1] and we imagine it to be also the date of the umbrellas. Mr. Werner cites the Jesuit Père Henri Doré as one of his chief authorities outside the innumerable Chinese MSS. which he has consulted and lived among since leaving Tonbridge School more than 40 years ago.

BISMUTH AS AN ANTILUETIC.

In a special number of the *Paris Médical* (Dec. 2nd, 1922), devoted to recent advances in therapeutics, Dr. E. Émery and Dr. Alexandre Morin, of the Saint Lazare Infirmary, Paris, remark that the most interesting therapeutical acquisition within the last few months is the use of bismuth in the treatment of syphilis. This is not an absolute novelty, since it had been employed by Balzer at the Lourcine Hospital in Paris as long ago as 1888, but it was only after the work of Saverac and Levaditi in 1920, following that of Sauton and Robert in 1916 on its use in trypanosomiasis and spirilloses, that bismuth became generally recognised as an antisyphilitic drug.

Investigations of numerous observers, especially those of Saverac and Levaditi, have shown that whatever method of administration or preparation of bismuth is employed, the active substance is metallic bismuth. Its mode of action therefore more closely resembles that of mercury than that of arsenic. In the course of its administration bismuth becomes widely disseminated throughout the organism, chemical analysis having shown it to be present in the blood, cerebrospinal fluid, and almost all the organs, especially the liver, salivary glands, heart, and spleen. It has been detected in bile, urine, saliva, sweat, and fæces, in all of which it is rapidly eliminated. When used in suitable doses bismuth preparations have been found to be very active in all stages of syphilis, excluding parasyphilis. In the primary stage the time which the chancre takes to heal varies according to the size of the lesion; on the average it is 13 days with 4 injections, but it may be as short as 4 days with a single injection, or as long as 25 days with 8 injections. In the secondary stage the cure of mucous tubercles and oozing cutaneous surfaces takes place rapidly, and is effected on the average in 11 days with 3 or 4 injections. Émery and Morin agree with Clément Simon and Bralez in regarding the action of bismuth as far superior to that of mercury, and comparable to that of large doses of arsenobenzene. The same is to be said of the action of bismuth in tertiary syphilis, for gummata and osteitis show much more rapid improvement than with mercury according to these writers, whose views can be summarised as follows: Visceral syphilis, in particular gastric syphilis and aortic aneurysm, is greatly benefited by injections of bismuth. In syphilis of the nervous system bismuth acts best on the recent manifestations of the secondary stages, especially on neurorecurrences. The best proof, however, of the activity of bismuth, according to Emery and Morin, is furnished by its effect on the Wassermann reaction. If the drug is employed early it prevents the reaction from becoming positive, while if it is delayed it renders the reaction negative, though not so rapidly as is done by arsenical compounds. Among the numerous preparations of bismuth employed in the treatment of syphilis the most popular are the tartrobismuthate of sodium and potassium, hydrated bismuth oxide, and the iodobismuthate of quinine. Other preparations sometimes used are colloidal bismuth, precipitated bismuth, and ditrioxybismuthobenzol. All these preparations may be and are best given intramuscularly, though colloidal bismuth and ditrioxybismuthobenzol may also be administered intravenously. The advantages of bismuth medication consist in the fact that it is well borne, that it avoids the risks of arsenical preparations, that it occasionally is successful when arsenic fails, and that it apparently has a special action on neurorecurrences. Its drawbacks, such as local pain, skin eruptions, stomatitis, constipation, or more rarely diarrhœa, depression, and headache, are comparatively trifling, and are mainly due to unsuitable preparations or excessive dosage.

The writers believe that syphilis can be treated effectually in all its stages by bismuth alone, but do not advocate an exclusive bismuth treatment, recommending that it should be combined with arsenical preparations, and to a much less extent with mercury.

BARIUM SALTS IN MINERAL WATER.

Barium salts are rare constituents of natural waters, chiefly on account of the almost universal presence of sulphates and the exceedingly low solubility of this salt of barium. Where carefully tested for, even in the presence of sulphates, a trace may be found as in the mineral water at Buxton. In a mountain limestone water in mid-Derbyshire some milligrammes of barium were found to be present per 100 c.cm., sulphates being absent. Brandes found barium in the water of Pyrmont, and other authorities in the waters of Kreuznach and of Luhatschovitz. Barium is also known to be present in the sulphur water of Harrogate, and in the water from the mineral spring at Llangammarch (Wales). The last named is said to contain about 6 gr. of the chloride per gallon. Mr. A. Woodmansey, analyst to the Royal Baths, Harrogate, announces this week in our columns that two other springs in that locality contain appreciable quantities of barium—namely, the "Chloride of Iron" spring and the "Magnesia well." Whatever medicinal effect barium salts may produce can be obtained by the use of these waters. It is one of the few constituents of mineral waters to be credited with appreciable action upon the heart. In several foreign pharmacopœias the chloride of barium is included, but in this country barium salts have never been used to an extent to justify inclusion in the official register. Barium sulphate is employed somewhat extensively as an opaque meal prior to X ray examination, when, of course, great care must be taken that all soluble salts of barium have been washed out. These soluble salts are distinctly toxic, although they are absorbed but slowly by the lining membrane of the alimentary canal. After absorption a portion is stored in the bones but most is excreted in the urine. The chief action of barium salts is to accelerate the heart and increase the blood pressure, at least for a time, and it is quite possible, therefore, that waters containing them may be beneficial in judiciously selected cases.

We regret to announce the death on Dec. 30th last of Dr. John Berry Haycraft, Emeritus Professor of Physiology in the University of Wales, at the age of 65.

The Royal Society of Medicine will hold a special meeting at 8.30 P.M. on Friday, Jan. 26th, to commemorate the centenary of the death of Edward Jenner. A lecture on Jenner's life and work will be given, and several objects of historical interest will be shown. Sir William Hale-White will preside.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

I.

THE MEDICAL TREATMENT OF GALL-BLADDER DISEASE.

THE treatment of inflammation of the gall-bladder and its consequences is largely in the hands of the surgeons, for by the time that the site of the trouble can be unhesitatingly recognised the lesions are commonly so advanced that a permanent cure can only certainly be anticipated from operation. In the early stages of the milder cases the symptoms are often reflex and gastric, such as flatulent indigestion, rather than definitely localised to the gall-bladder region, but even in such instances deep pressure often brings out local tenderness. In addition to this group of cases there are others in which medical rather than surgical treatment is reasonable; there are acute cases of "catarrhal" jaundice and of jaundice with or without tenderness and resistance over the gall-bladder occurring in association with some infection, such as enteric fever or influenza.

Relation to "Bilious Attacks."

Recurrent subacute bouts of gastric indigestion without jaundice but with slight transient pain and tenderness over the gall-bladder and liver, which may be enlarged (for it has now been shown that inflammation of the gall-bladder is accompanied by hepatitis), are often regarded as much the same as "bilious" attacks or "chill on the liver." The nature of these two popular disturbances is somewhat doubtful and may vary in different instances; some are probably merely due to excess or errors in diet causing toxic functional disorder of the liver cells; indeed it may well be that both the liver itself and the gall-bladder suffer in varying degree in different cases, tenderness of the gall-bladder, of course, being a guide in forming an opinion on this point. In the absence of any definite evidence of implication of the gall-bladder treatment should consist in removal of the cause, whether infective, such as a septic focus, or toxic, from unsuitable food; rest to the liver by restriction of food verging on starvation, and by purgation by the time-honoured administration of mercury in some form or other, followed by salts. Minute doses ($\frac{1}{20}$ gr.) of calomel three times a day exert an antiseptic, though not a purgative, action on the intestine, and are often of apparent value.

More Serious Cases.

In addition to these mild cases there are not infrequently cases in which surgical treatment, though the ideal course, is either firmly declined by the patient or rendered inadvisable, at least for the time, by his or her condition. It must, however, be remembered that a frequent contraindication to operation is the condition of the heart—a toxic myocarditis—which is secondary to the gall-bladder infection and will continue, if not progress, until that is removed or improved; the risk of operation therefore is one that may have to be taken. Much may be accomplished, however, by careful medical treatment. During an attack of indigestion, pain and tenderness over the gall-bladder, with or without fever, the patient should remain in bed on a light fluid, but not too milky, diet, with hot applications to the hepatic region, and take three times a day before food a mixture containing hexamine (urotropin), which has been shown experimentally to remove infection of the gall-bladder even though the bile is alkaline; salicylate of sodium, which acts as a cholagogue, though its power in this respect has been rather variously estimated, thus helping to wash out the gall-bladder and so to remove infection; benzoate of sodium, bicarbonate of sodium, spirits of chloroform, and infusion of cloves. Hexamine should be given at first in doses of 7½ gr. and gradually increased; some patients find that it upsets their digestion, others that it irritates the urinary bladder, and in this event the last dose of the medicine should be taken before 4 P.M. so as to avoid disturbance of sleep during the night; in rather rare instances its irritating effect on the kidneys sets up hæmaturia. This mixture should be continued for six weeks after an attack so as if possible to eliminate infection; it may possibly also be of use in cases in which gall-stones are present, for there is some experimental reason to believe that gall-stones may be dissolved in the gall-bladder if a flow of healthy bile over them is restored. Single pure cholesterol calculi may form in gall-bladders which do not show any evidence of inflammation, and in such instances a normal bile may be more easily obtained than in cases of cholecystitis, and so the calculus may conceivably be dissolved. After the attack has passed off the diet should be carefully supervised so as avoid or restrict those articles of food that contain or produce cholesterol, and so would tend to favour the formation of biliary calculi; these are yolk of eggs, brains, fats, butter, stewed and fried foods, goose, duck, sweetbread, liver, kidneys, and green peas. Stagnation of bile in the gall-bladder should be counteracted by frequent small meals which lead to corresponding evacuations of the gall-bladder, and by exercise, especially those forms which entail free excursions of the diaphragm and liver. When purgation is necessary those drugs should be employed which appear to empty the gall-bladder, such as blue pill or calomel at night, followed next morning by sulphate of sodium or sulphate of magnesium in as nearly a saturated solution as possible. Lyon's method of medical drainage of the bile-ducts and gall-bladder by means of a duodenal tube, after spraying with a solution of magnesium sulphate to relax the sphincter at the lower end of the common bile-duct, may in the future become as familiar as gastric lavage, though the technique is more elaborate. It has proved useful not only in diagnosis, but in the treatment of "catarrhal" jaundice, cholecystitis in an early stage, and as a post-operative auxiliary.

Prophylactic Treatment.

An important point in the prevention of recurrent attacks of gall-bladder inflammation is the removal of any primary focus from which infection may be conveyed to the gall-bladder; it has been shown that streptococci from the tonsils are specially prone to settle down in the gall-bladder, and hence oral sepsis, which often precedes and causes tonsillitis, should be treated; similarly suppuration in the accessory nasal sinuses should be sought for and cured. Other foci less easily dealt with are appendicitis and pelvic infections in women. Another prophylactic measure is the avoidance of the articles of diet mentioned above as prone to increase the cholesterol content of the blood, especially in the later months of pregnancy and after delivery, when there is already an increased percentage of cholesterol in the blood.

Special Articles.

MEDICAL INSPECTION IN SECONDARY SCHOOLS.

BY C. W. HUTT, M.D. CAMB., D.P.H. OXF.,
MEDICAL OFFICER OF HEALTH TO THE METROPOLITAN BOROUGH OF HOLBORN.

MEDICAL inspection in secondary schools has been carried out in a more or less complete manner voluntarily for some years by various authorities, such as Brighton, Sheffield, &c. The success of medical inspection and treatment in public elementary schools made it certain that sooner or later the benefit would be extended to secondary schools. Largely doubtless to the delaying influence of the war it was not until April 1st, 1920, that the Education Act of 1918 made inspection and treatment compulsory. An economy circular has, however, since made inspection more or less compulsory and treatment voluntary. By the end of 1921, 119 of the 145 local education authorities concerned have made arrangements for carrying out their obligations under Section 18 of the Education Act, 1918. The number of secondary schools medically inspected in 1921 was 860, the number of pupils medically inspected was 135,000.

Medical Examination before Admission.

To be logical one should commence with the need for medical examination before admission. It must be within the experience of most secondary school medical inspectors that there are a number of children filling valuable places who are quite unable to benefit by these special educational facilities. Some, for instance, are practically stone deaf, others have very marked defects of vision—a preliminary medical examination before entrance would not only eliminate these children and provide their parents with more or less sound advice as to how their education could best be carried on, but would discover at the earliest possible moment, scholastically speaking, the presence of numerous defects often readily curable which nevertheless reduce the ease with which the children assimilate the education offered.

Closely allied to this subject is the matter of the free places which must be offered to children entered from public elementary schools. As is well known, these are ordinarily 25 per cent. of the total school attendance and efforts have been made to increase this percentage to 40. The value of the scholarship provided is free tuition only; but many committees, such as, for instance, the Surrey County Council, give a number of exhibitions to free-place scholars; the value of this exhibition is such as is sufficient to meet the amount necessary for travelling expenses, together with proper school charges for books, stationery, &c. The value does not include dinner allowance, but we are told the committee will be prepared to consider applications entirely on their merits, having regard to the distance of residence from the secondary school and the position of their parents.

It is not my duty nor my function to comment on the policy or the advisability of these steps, but it is within the scope of those interested in the health of secondary school-children to suggest that if the children of poor parents are to be admitted to public secondary schools free of charge, the monetary allowance made shall be sufficiently large to cover the necessary expenditure adequately. In this way only will mental and physical suffering of the school-children be avoided. It is eminently conceivable that the parents' financial circumstances may be such that they cannot provide for the maintenance of the child at a secondary school without detriment to his health and deprivations, which must tell not only on his health but also on the health of any other children in the family. To put the matter somewhat bluntly, it really comes to this: if the parents are too poor, on health grounds the child should *not* be nominated for a free place unless the local education authority or the State are prepared to offer adequate financial help.

Results of Medical Inspection of Secondary School-children.

Doubtless many experienced school doctors could have foretold the results to be obtained from the medical inspection of secondary school-children; obviously the differences from these facts elicited by work among elementary school-children would arise from the different social status and age of the pupils. Owing to the different social status it would seem probable that the matter of vermin would be of less importance. This is borne out by facts; although verminous children are still found in the secondary school, they are very few in number. In 1919, on inspecting the girls holding scholarships at a provincial municipal secondary school, 12 out of 56 were found to have nits in their hair. Fortunately, however, at this school now that medical inspection is in full swing, and every child over 12 is examined once a year, the number of girls with nits has been very much reduced; in fact, at the last six inspections no instances have been reported. Infestation with body lice is practically never found.

In the secondary school deficiencies as regards clothing are rare. The school authorities are justified in asking for correct clothing for physical exercises. At the Municipal Secondary School for Boys, Brighton, the boys are required to change their shoes at school, and to wear "low-heeled house shoes or slippers." In the gymnasium, every boy makes a complete change into shorts and singlet; braces are not allowed. Rubber shoes only are worn—in most cases these are used in the school also. At the girls' school low-heeled house shoes must be worn during school hours. These, when not in use, must be kept in the bags provided for the purpose. Hair must be neatly tied back during school hours with navy blue or black ribbon; hat-pins and jewellery, with the exception of a brooch or watch chain, may not be worn. Every girl must have a pocket in her dress. For the drill lesson, the regulation tunic, blouse, and black gymnasium shoes and stockings must be worn, and no stays or tight clothing of any description. The hair must be neatly plaited; combs may not be worn. The tunic and blouse must be made according to the school pattern, which can be obtained from the office. The blouse must have sleeves long enough to allow the arms to be easily stretched above the head.

The parents of the secondary school child are often sufficiently foresighted as to consult the secondary school doctor if they hope to put the child into a service or branch of a service in which there is a definite statement of the requirements as to the physical condition of entrants. The parents will probably consult the secondary school medical inspector much more in this connexion than in the case of public elementary schools; in this way it should be increasingly possible, for instance, to prevent the boy or girl with high myopic astigmatism from taking up teaching as a profession.

The fundamental aim of keeping the child healthy so that he can learn in school is the same in both elementary and secondary schools. In both types of school we have to guard him against infectious diseases; to see as far as lies in our power that his life out of school hours is hygienic; to prevent excessive indulgence in the cinema; to encourage games out of school hours.

Sleep.

We should not have the same difficulties about sleep as in the case of elementary school-children. The children we are considering very rarely, if ever, live in drunken neighbourhoods where the noise of revellers is continued far into the night, nor do they often live under the same roof with families of this kind. If it has been found necessary to issue warnings to children attending secondary schools in connexion with summer time the fact has escaped the notice of the writer. But there often is need for advice on the matter; the Jews, who are so good to their children, are perhaps especially prone to over-indulgence in this respect, and allow their children to stay up too late.

The hours of sleep for secondary schools to be recommended are:—

At the ages 8–11 years	11 hours.
„ „ 12–14 „	10½–10 hours.
„ „ 14–16 „	10–9½ hours
„ „ 16–18	9½–9 hours.

These are minimum periods, hours actually spent in bed. Half an hour should be added for undressing; thus a child of 16 who gets up at 7.30 will start going to bed at 9.30. Although these periods are shorter than those advised by some school doctors, it should be borne in mind that if the child is allowed to stay up another half an hour this allows the game of tennis to be finished or of a cycle ride; time for culture, reading, and games generally must also be found. These periods should be increased at discretion; if a child flags, or if his or her work is deteriorating by reason of too little sleep, obviously longer hours should be recommended. The matter of hours of sleep should be made one of school discipline.

Arrangements for Midday Meals.

Suitable arrangements for midday meals are those made at the Dudley Girls' High School, a municipal secondary day school. Hot dinner is provided at a charge of 11*d*. There are about 120 children who take the school dinner. About 100 more bring their own cold lunch and have the use of a room in which tables are properly laid for them. They pay 2*d*. weekly for the use of this room and its equipment. The advantage of such provision from the health point of view is obvious.

Eyesight.

Much insistence is necessary in connexion with harmful type. One of the books most commonly at fault is the combined Common Prayer and Hymn Book, which unfortunately makes a convenient birthday present. Although the giver may hold that the child "only reads it for a quarter of an hour at a time," the book is often read in a poorly lighted place; obviously the fact that many Bibles are printed in equally harmful type is no argument in favour of the use of any book the type of which fails to come up to the required standard. A certain weekly paper brought out for school girls is printed in type which is far too small; the small dictionaries bought for a penny, and unfortunately at times recommended by head teachers, are even worse. That smallness of type is not only harmful to the eyesight is borne out by the well-known warning, "To prevent curvature of the spine give the children large print." The attention of parents and of those persons responsible for the purchase of books for secondary schools should be drawn to the British Association report on the influence of the type of text-books, &c., on eyesight. The report deals fully with all kinds of school books, maps, &c. As long ago as 1914 the B.A. Committee reported against the use of glossy paper and described a gloss-tester; hence by now any publisher should have avoided producing books which are injuriously glossy. Very satisfactory *unvarnished* wall-maps can now be obtained; all highly glazed maps should be expelled from class-rooms.

It would be advantageous if all local education authorities would undertake the testing of school books, writing papers, and maps with reference to influence upon eyesight, and refuse to purchase or allow the use in their schools of any publication found unsatisfactory in this respect.

Colour Vision.—Obviously considerable importance attaches to the testing of colour vision. Following Dr. Dunstan Brewer, of Swindon, I would suggest that the best method of examining colour vision is to employ the Edridge-Green bead test. This can be performed by the children when waiting their turn for inspection. It is unfailing for detection of any serious form of colour-blindness. If the beads are placed in the proper position it can be held that dangerous colour-blindness is absent; yet, on the other hand, no definite conclusions can be drawn from failure, so that should the child fail with the bead test another must be given before a final conclusion can be drawn. The Edridge-Green card test is probably the most trustworthy and most delicate test we possess, yet, like the Binet tests, the results require to be very carefully considered before an opinion should be expressed. Although the lantern test is very suitable for the detection of dangerous cases of colour-blindness its use is probably not practicable in schools. Wool tests are hardly worth doing.

As an example of the results from testing colour vision in 1921 in Sheffield eight boys out of 775 had deficient colour sense; not one of 763 girls presented this defect. Similarly, in Brighton, four cases of colour-blindness were discovered in 1921 among boys, 0·6 per cent., none in girls. This result is in accordance with the proportion usually found among the population generally, and with the fact that colour-blindness is very rare in girls. The deficiency found was of the green-red type. The vision of all four children was otherwise practically normal.

Homework.

In London among secondary school-children circulatory troubles and anæmia are too common; they are more frequently found than in elementary schools. Doubtless preparation for examinations and homework are harmful to many girls below tone and in a condition of nervous debility. As an example of too extended schoolwork the school medical staff elicited that in one London secondary school on Saturdays the girls attended school till 12.30, and then had three and a half to four hours' homework.

But it will be found from time to time that where the parents have complained of the length of the homework the scholar has various other interests or even duties which occupy his time, and the blame for keeping late hours is incorrectly laid on the homework. This fault occurs not only in schools of this type, but also in the day public schools; in one such school with a large Jewish element some boys attend Hebrew classes in addition to their homework for school. When we add the factor of the restricted home, a factor present in some instances, we can easily explain the seemingly less output of energy occurring during adolescence in these pupils.

In the ordinary secondary school the daily homework usually varies from 30 minutes in the lowest form to two hours in the highest. The work is not, as a rule, strenuous; it often consists of copying notes, map-making, and the like. Frequently part of the "home" work is done in school; in many schools it is reduced during the summer months. An excellent arrangement is for the amount of homework to be posted in each class-room, and for each child to have a diary in which is entered the time allotted to each homework lesson. The boys or girls should enter the time actually taken each night, and this diary should be initialled weekly by the parent and by the form teacher, and the diaries personally supervised by the head of the school.

Travelling to School.

Evidence as to the influence on health of children travelling long distances to school is very scanty. In Cumberland, however, a number of parents in one area having complained that the travelling was prejudicially affecting their children's health, Dr. Kenneth Fraser made careful comparison, at the request of the headmaster, between the children living locally and those travelling from a distance. The numbers examined were very considerable, and the comparison was made without the school doctor knowing which belonged to the group. He found that there were *fewer* defects—such as anæmia, debility, lung affections, &c.—which might be attributed in whole or part to overstrain among those who travelled from a distance of seven or eight miles daily than among the local children.

Mental Condition.

The problem of backward boys in public and municipal day-schools is dismissed rather than solved by the superannuation of those who cannot advance with the average boy. A boy in the lower school of a public school after the age of 16 "leaves" sooner. Presumably much the same occurs in the case of girls. Backward school children of a higher social standing than public elementary school children are at present presumably provided for in private schools or handed over to rural clergymen for education. Whether a larger measure of public control over the education of such children is desirable or not is a question which will ultimately require answering by lay and medical educationists.

Moral imbeciles are merely dismissed from public schools, and in consequence from the point of view of the prevention of crime it is doubtful whether such persons are dealt with at a sufficiently early period of their career.

Puberty.

Passing now to the subject of puberty, I would suggest that many of the views of educationists on puberty up to the present have been derived from the ancient Greek philosophers. Perhaps the opportunity now afforded to the medical profession of routine observation of a large number of children in this connexion will do much to promote a more exact knowledge of this period of life. Puberty may be considered to commence about the time the elementary school child is leaving school. In girls in the Temperate Zone puberty does not usually set in before the fourteenth or fifteenth year. The age of puberty in a healthy male in this country varies from 14 to 17 years, the date of its appearance being affected by the boy's constitution and moral circumstances under which he is placed.

In the immediate past we have been told, largely by non-medical writers, that the systems of circulation and digestion, in their endeavour to meet the variety of strains caused by the development, are particularly liable to disorder; also that this is the period when habits of alcoholism are initiated and established, and when the craving for the similitude of manliness requires the assistance of tobacco. But one feels that the need for alteration of the habits of children of this age will probably be very slight. Again, we are told the central fact of adolescence is emotional change. Observations by medical men of members of their own family, however, tend to bear out this statement. While awaiting research of this psychological subject, in the meantime it would seem advisable that all school doctors dealing with secondary school children should use their influence to prevent any excessive punishment for breaches of discipline which clearly have their origin in the altered emotional state due to the certain physical change.

Masturbation is a matter which merits attention; every school doctor should have formed his own opinion on the subject. I do not know if the new work will enable us to get to the truth of the extent of masturbation. This trouble has been variously held to commence at the age of 8, 10, or 11 years; in a large proportion of the cases we are told that it has been learned and practised before a boy has got into his teens. "Adequate and timely instruction of all" might be held to be unnecessary; possibly a general remark or so by one of the boy's parents is better than anything else. Just as a girl should be told that the loss of blood from the genital organs is natural at a certain time, so should boys be told that seminal emissions are matters of very little import. When the practice is suspected, the school doctor might have a talk with the boy after having seen the parents, and the evil effects of the practice pointed out without any unfortunate exaggeration. At the same time an investigation should be made into the child's mental life and any desirable physical examination made to discover an obstacle to the sublimation of the sexual impulse.

Games.

Whether we agree that games play too great a part in the post-war curriculum of the secondary school child or not, we have to acknowledge the fact that games loom very largely in his school life. The extent to which games can be indulged varies considerably in the type of school: the town municipal secondary school, the public day-school, and the public boarding school; but in any event, owing to the raised age of most of the children, official games play a larger part in their curriculum than in the case of the public elementary school child. The playing fields of urban secondary schools especially are conspicuous by their absence, and the possibilities generally for games are more limited or less utilised. In practice at present heart lesions appear to be of more interest to the municipal secondary school doctor than other conditions. In girls' schools it would seem that strenuous games like hockey are played by pupils affected with heart lesions. At Brighton, for instance, in 1921 four girls were advised to discontinue the game and their practice of physical exercises moderated to prevent fatigue or strain. Similar advice was required in the boys' school. Probably, however, at present it is only in the boarding schools that we find adequate opportunities for applying the criteria of fitness for games. These are:—

1. General physique.
2. *Heart.*—Normal area of cardiac dullness—normal sounds—normal reaction on examination after exercise. Any increase of cardiac dullness or alteration of sounds demands inquiry; test urine and arteries for cardiac vascular and renal diseases, e.g., post-nephritic trouble.
3. *Lungs.*—The points of interest are: Absence of disease on examination; effect of old pleurisy with adhesions limiting expansion. Expansion should be satisfactory—e.g., 2 inches—otherwise exercise is likely to be fatiguing.
4. *Hæmic Diseases*—e.g., anæmia. Moderate exercise only is advisable.
5. *General routine medical inspection* should be utilised to eliminate the unfit from games, and also to enable grading of exercise—e.g., fives, squash, tennis, cricket, football, cross-country running, &c.—to be advised in appropriate instances.

It is interesting to note that examinations of the urine of children at a London public elementary school revealed the presence of much albuminuria. In December, 1920, of 397 children examined, 91 showed the presence of albuminuria—i.e., not less than 20 per cent. This albuminuria must be considered as physiological in character. From the investigation made it would appear that the more boys are trained for sports the more likely are they to have albuminuria.

In most municipal secondary schools there is a fully trained teacher of physical education, fortunately of the same standing as teachers of other subjects. Usually the gymnastic master or mistress is present at the medical inspection. As a matter of fact they should always be present at medical inspections and any defects of the children, especially those of growth, pointed out to them. At the swimming baths these teachers have excellent opportunities of observing the children's physique, and are thus in a position to inform the school doctor as to each child's muscular capacity.

The condition of the water of swimming baths is not without interest. Although the exact amount of disease caused by dirty water in swimming baths cannot at present be stated, it is difficult to avoid a prejudice in favour of clean water. The advisability of disinfection of swimming-bath water should be borne in mind if circumstances make this precaution desirable.

Games for Girls.

A committee was formed in October, 1921, at the instance of the College of Preceptors, to consider physical education for girls and its possible harmful effects. The report of the medical members of the committee might be considered by some to be too cautious. Very few can disagree with the view that any game might become unsuitable if practised in such a degree as to cause undue strain or fatigue; also that the balance between the amount of exertion and the amount of fatigue may, on examination, result in the girl having to play games less strenuously. But although the committee considered that the use of gymnastic apparatus needs special care as injurious effects might come from exertion of this sort it might be maintained that very little evidence is forthcoming on this point. With regard to restriction of physical exertion during menstrual periods the medical members of the joint committee are not prepared at the present to state any opinion on the question. I would suggest that the position can be taken up that there is no clear proof that the physical education of girls produces any undue strain and that for girls is a distinct advantage.

The only form of sport condemned by the committee was football, but it is difficult to see in what respects this game is much "harder" than hockey. Very few will quarrel with the view that no one game need be exclusively played, and that the main aim is that the girls should leave school with well-set bodies as well as well-set minds, having already formed habits of love of open air, walking, games, and other pursuits to bring them into the open air as much as possible in after-life.

It is a matter for regret that under present conditions those children who most require the benefit of physical exercise through their lack of skill find difficulty in playing games for the reason that these are run too much for the benefit of the better players. In a school which is thoroughly well organised with regard to physical education the responsible persons would insist on making this type of child play the games. As it is, the most we can expect at present is for the child to perform the "physical exercises," which must be put into the curriculum unfortunately. If the proverbial man from Mars were to visit the earth one of the most extraordinary of spectacles provided for his delectation would be numbers of boys and girls arranged in rows making absurd movements at the command of the teacher. It is difficult to hold that these physical exercises are nothing but an unfortunate necessity, they are merely "corrective," using the word in its widest sense—that is to say, they have to make up for deficiencies in the provision and equipment, and especially in the organisation of a school for physical education. An interesting suggestion, which owes its origin to Dr. R. H. Crowley, is that an experiment should be made to see how far the exercise obtained in the carpentry shop, the blacksmith's shop, &c., attached to schools (Oundle being especially well equipped in this direction) can take the place of these physical exercises. Obviously, however, at present these physical exercises are very useful in connexion with minor deformities due to growth, such as flat chest, also for poor physique and postural spinal curvature. For the sake of clarity it is perhaps advisable to hold that for spinal curvature of a marked degree special remedial gymnastics should be given by the physical instructor under the supervision of the school medical officer, while for deformities of a greater degree the orthopædic clinic is, of course, necessary.

At a Medical Congress on Physical Education recently held in France, the general consensus of opinion was that systematic teaching in connexion with this subject should be given to students at the large hospitals; in this country the already overloaded medical curriculum would appear to make us face the fact that any such teaching must be provided in post-graduate classes for those medical practitioners who are especially concerned in this branch of medical work. A body such as the Central Committee for the Care of Cripples, or a committee with similar functions, is apparently the one most appropriate to organise the much overdue course on the medical aspects of physical education.

TREATMENT OF THE BLINDED SOLDIER:

A COMPARISON OF GERMAN AND BRITISH METHODS.

Captain Ian Fraser, chairman of the Blinded Soldiers' and Sailors' Hostel, commonly known as St. Dunstan's, has recently returned from a short stay in Berlin, whither he went at the request of the committee of St. Dunstan's to investigate the re-education, training, and after-care provided by the German people for their blinded soldiers. What follows is an abridged account of his visit in his own words.

The Numbers of the War-Blinded.

Properly to appreciate the conditions under which these men are living it is necessary to have some idea of the general economic and social life in Germany, so that I shall deal in this article not solely with my mission, but with inquiries of a general character which I was obliged to make. There are, it appears, between 3500 and 4200 Germans blinded in the war. The British Empire suffered about 2000 similar casualties; the French Republic, as far as we know, between 3000 and 3500, and the Belgians and Americans perhaps 100 or 125 together. When the number of Russian soldiers blinded before the Revolution is added, the number of Germans blinded is evidently very much less than the total number amongst the Allies engaged upon the German fronts. This is not, of course, strange, for the German casualties were less than ours throughout the war, mainly because the German armies were fighting upon interior lines. Thinking that I might find an additional reason for their relatively small number of blind casualties, and remembering how ingenious were the Germans in the construction of protective devices in their trenches, I inquired if they had developed some form of face protection against high-explosive shell splinters, but could hear of no such thing. It will be remembered that one or two unsuccessful efforts were made in England to devise some form of screen or visor for this purpose. As amongst British soldiers, only a few had suffered eye wounds from bullets, grenades, &c. Some of the men we saw were abnormally mutilated, but whether this was due to the greater destructive power of our weapons, or to the possibility that the most severely wounded men would naturally preponderate amongst those still being re-educated at a date so distant from the cessation of hostilities, I do not know.

Nature of Injuries.

As far as I could gather, there is no soldier who has been both totally deafened and blinded in Germany, though, as in this country, there are a good many whose hearing has been affected in a more or less serious degree. Also, apart from temporary blindness, there is not a case on record of a man having lost his sight from gas. Contrary to the general belief on this subject, this is also the case in England. Inflammation of the frontal sinus and similar head troubles were fairly numerous, I was informed by an eminent ophthalmic surgeon in Berlin, and they have been treated in much the same way as our surgeons have dealt with similar cases here. This same professor told me that there have been one or two isolated instances in which men who had detached retina had been given back a certain amount of sight by operations, but that these were extremely rare. This again is similar to English experience.

International Resemblances.

The same informant happened to be adviser to the German Ministry of Pensions upon the very difficult subject of the attributability to or aggravation by war service of a man's condition, and I gathered from him that in this matter, as indeed in almost all questions of principle affecting the award of pensions, the German system was almost exactly like ours. I was very struck by the similarity between German laws and our laws on this subject, and was inclined to form the opinion, which at first I hesitated to hold, that the German mentality, the German idea of justice, and the degree to which they are possessed of the quality of sympathy were extremely like our own. I discussed this matter with one or two intelligent observers of German psychology who had been in the country both before and since the war, and also with many British officers on the Commission of Control, and found that they held exactly the same view. Now that the Germans have scourged themselves of Prussianism, which was a blight upon a peace-loving people, I am convinced that they are a race who are entitled to more respect and consideration than many Englishmen are prepared openly to give them.

Conditions in Germany.

The German people are extremely poor. This fact, and not, I think, any lack of sympathy on their part, is the cause of the miserably insufficient pensions which their disabled men receive. I made a number of inquiries among working men and employers in regard to wages, and though I would hesitate to put forward these figures with absolute certainty I think it is fairly safe to say that 5000 marks in Germany were worth last month to a working man about 19*s*. or £1. Now the Berlin tram-driver, or a taxi-driver, or any ordinary working man, engaged in an occupation of this standing, gets 5000 or 6000 marks a week. This enables him to purchase for himself and his family about the same value in housing, food, clothes, &c., as an Englishman could obtain for £1 or 21*s*. There is not so much unemployment in Germany as in England, but there is infinitely more poverty, infinitely more suffering, and very much less food. I believe that Germany is enjoying a period of good trade similar to that which we enjoyed for a year or 18 months after the war, and that immediately the printing of paper money is curtailed, as it must be curtailed, acute depression and unemployment will be experienced. I cannot speak of conditions in the country districts, for I was too busily engaged to be able to leave Berlin; but in that city German working men and women, on full work, are existing upon weekly incomes which leave them considerably worse off than those who are unfortunately unemployed in this country. The idea many Englishmen have that the Germans are doing well, and that the war has left them better off than ourselves, is clearly wrong.

The Individual German Blinded Pensioner.

The pension received by a German blinded soldier is about 7000 marks a month, with an allowance of 1400 marks a month for each child. This means that a married man with two children has about 10,000, or approximately £2 a month, if my estimate of the purchasing power of German money in Germany be correct. No attendant allowance is made, but to the above amount must be added about 400 marks per month, allowed for the upkeep of the dog-guide provided instead by the State for each blinded soldier. This, or any other guide, is allowed to travel on railways free, and in addition veterinary attention for the dog is provided, at State expense, if required. Judging from remarks made to me by individual blinded soldiers the dogs are a great asset, and probably 3000 men use them. They are the same type of dog as the police-dog which was used by the Germans, and I think by some of the Allied Armies, for the carrying of messages, and in connexion with medical services in the field, during the war. Trained at a special State-owned farm, these dogs are remarkably efficient as guides. They wear a sort of harness round their shoulders, with a stiff leather handle about a foot long coming up almost in a vertical position from the middle of the animal's shoulders. The blinded soldier holds on to this handle, and is thus able to feel any forward, backward, or sideways movement of his guide. When the dog's blind owner desires to cross a road, the dog sits down, and no amount of impatience on his owner's part will make him move forward until the way is clear. The dogs are most unnatural as far as their relations with their own kind are concerned, for they pass them by with complete indifference. Whether or not the dogs are trained by harsh treatment I cannot say, but they are certainly affectionately regarded by their owners, and are well looked after. Nevertheless, I should not like, and I do not believe British blinded soldiers would like, to be accompanied in both town and country by an animal with an elaborate harness and a red cross on each shoulder.

Training for the Blinded.

There are only two services rendered to blinded soldiers in Germany which resemble in the least the activities of St. Dunstan's. One is a school in Berlin, in which about 500 of their men have had the opportunity of learning Braille and typewriting, massage, shorthand-writing, telephone-operating, &c., and of adapting themselves as did a few of the St. Dunstan's men, for a return to their pre-war occupations. But though the same subjects were taught in this school as at St. Dunstan's a much smaller degree of success has apparently been attained. For example, only ten masseurs were trained, and then the idea was given up because the men were unable to do well. Whether this is due to the training, or to other conditions over which the school had no control, I was unable to find out. But there must have been an enormous demand for masseurs in connexion with war injuries, and had the training been good there would at least have been a temporary boom in this work for blinded men. Telephone-operating, again, has only been a partial success, for the only men at present employed are those who were previously working in the German Post Office. With stenography and typewriting they appear to have had better results, for 80 or 90 men, employed all over Germany, are said to be doing relatively well. An exact copy of the shorthand machine supplied to English blinded soldiers is being used by the Germans.

The second direction in which German blinded soldiers are able to obtain assistance similar to that available for Englishmen is in connexion with pension inquiries, for there is an organisation, very meagrely supported by voluntary subscription, which does for them what the St. Dunstan's pensions department does for our men. Apart from the 500 men I have mentioned, who went through the Berlin school, and prepared themselves for professional life, there have been practically no special arrangements made for German blinded soldiers by the State or by voluntary enterprise, and the remaining 3500 or more of their men were left uncared for with the exception of a few who found their way into civilian blind institutions, until the employment of disabled men in factories was made obligatory upon employers by the State. It appears that some of those who went into civilian blind institutions stayed there, doing brush-making and basket-making, and if the conditions in the largest civilian blind workshops in Berlin, which I visited, are at all similar to those in the provincial institutions, I do not envy the men their lot. Others, however, merely passed through a period of training and then returned to their homes. In some cases they were given tools and equipment, but in no case did they receive any form of after-care, and thus only a small number have been able to make a success of their work. When the Act for compulsory employment of disabled men in factories was passed, local committees, rather similar to our employment exchanges, or war pensions committees, were set up all over the country, and a register of all employers in their districts was kept.

The employer was obliged to take into his works or factory a number of men, having a disablement greater than 50 per cent., amounting to not less than 2 per cent. of the total number of his workmen.

A blinded soldier would apply to a committee for employment. Through their register they would see where there was a vacancy, and would send him along. From this point the State ceased to have any interest in the man, and it was up to the employer to do what he could to fit him into his business. I fear that the majority of employers have put their blinded men on to dull, unskilled, monotonous work. There are amongst employers, however, one or two notable exceptions, who seem honestly to have considered the welfare of their men. Foremost amongst these is Siemens' Electrical Works at Siemenstatt, a few miles outside Berlin. Here, in one workshop where small metal parts are manufactured, there are 80 blinded soldiers amongst two or three hundred sighted employees. They fit into the routine of this factory, each doing an automatic job with an electrically driven machine specially adapted for his use. This is the only example of really good factory employment for the German blind on a large scale. The men earn piece-work wages about equal to women employed upon similar machines, or about 80 per cent. of the wages of sighted unskilled workmen. The striking thing here is not the skill of the blind men, which though good is not surprising, not the cleverness of the machines, but the goodwill of the firm. Even this work I should consider to be dreadfully monotonous, but practically the only alternative is idleness, and financial conditions, low pensions, &c., force the men to carry on. I feel there are few British blinded soldiers who would undertake this work, but it might meet a long-felt want for the civilian community, the majority of whom have no better alternative. I do not think I can honestly say that we have much to learn from Germany, but in view of the exaggerated reports we have had from time to time as to this work at Siemens I think it is a good thing that the matter should have been examined.

Briefly, then, I have come back from Germany with an increased regard—if that was possible—for my own country, and a greater pride in St. Dunstan's; and I am extremely thankful I am not a German blinded soldier.

ROUMANIA.

(FROM OUR OWN CORRESPONDENT.)

Precautions Against Cholera.

ON account of the prevalence of cholera in Russia and in some parts of Ukraine the President of the Roumanian Medical Council has laid down regulations with a view to preventing the importation of the disease into Roumania. Every person arriving at the frontier from a place infected with cholera, and presenting possible symptoms of the disease, will be detained at the railway station by an officer appointed for the purpose, and isolated until seen by a medical man. If the case is one of cholera, the commissary, acting in concert with the municipal authority, will convey the patient to some suitable place for isolation. Carriages which have been occupied by persons suffering from cholera must be emptied and disinfected. The bringing into Roumania, except as personal luggage, of dirty linen and soiled clothing or bedding from infected districts is forbidden by law. When lodgings are taken by persons who either come direct from infected places or have left such places within the preceding eight days, the householder must, within 24 hours of their arrival, report the fact to the nearest police medical station. Every suspected case of illness must also be reported immediately and all such cases isolated; preventive measures must be undertaken with respect both to the patient and to his contacts.

Infectivity of Tuberculosis.

The Bucharest Commission on Tuberculosis issued its report in November, giving definite answers to certain questions submitted for its consideration. These answers are derived from a number of experiments carried out on behalf of the Commission on a large Government farm, and may be thus summarised: (1) In many cases human tuberculosis is identical with the bovine disease; (2) mammals and man can be reciprocally infected with the disease; (3) tuberculosis can be communicated to man from infected cow's milk or tuberculous meat (pork or beef), but the danger from fowls, geese, and turkeys is negligible; (4) there are three distinct types of tubercle bacilli—avian, bovine, and human; (5) the bacillus of lupus is of the bovine order, but is of a modified type and differs in certain respects from the usual bovine bacillus found in cattle.

Antivivisection Movement in Roumania.

In Bucharest, the opponents of physiological research are endeavouring to revive the old argument that vivisection is useless for the advancement of medical science, and may even be the cause of disastrous errors. Forty or 50 persons, some of them well known, have formed a little society for the propagation of these views, but at their first meeting held recently in the city the attendance was small.

Dec. 26th, 1922.

MEDICINE IN U.S.A.

(FROM AN OCCASIONAL CORRESPONDENT.)

American Relief Work in the Near East.

WHATEVER may be her attitude in political matters America is still compromising her isolation in order to relieve sickness and suffering in the Old World. No sooner had the American Red Cross finally withdrawn from Europe than destitution and disease in the Near East summoned that generous organisation back with its irresistible appeal. The sums set aside for this new work already total close on a million and a half dollars. In order to help in the raising of funds, the President issued from the White House to the governors of all States an appeal in which he designated Sunday, Dec. 3rd, as "Near East emergency day."

Other Forms of Coöperation.

It will be remembered that the United States was represented at the second conference on the standardisation of antitoxins held under the auspices of the health section of the League of Nations at the end of November. It is now announced that Miss Grace Abbott, of the U.S. Children's Bureau, has been appointed to coöperate with the advisory committee of the League of Nations on traffic in women and children. The appointment is "unofficial" and Miss Abbott will serve in a "consultative capacity." These marks of a formal policy do not, however, disguise the real interest of the United States in all international work for health.

Street Accidents.

Evidence of the appalling risks which children run in our larger cities from automobile accidents continues to accumulate. The 1922 report of the Committee on Public Accident Statistics of Chicago, just issued, analyses the accidents reported in 1920: 13 per cent. of all accidental deaths were of children under five years of age. One-third of all people killed in automobile accidents were children under 15. Various attempts have been made to counteract this evil, which seems to be the necessary consequence of the widespread ownership of motor cars. "Safety-first" campaigns reduce the accidents only while the campaign is in progress, and automobile tragedies retain their place amongst the more important causes of death. A mayor of one large town has recently decreed that those convicted of dangerous driving shall be taken to the mortuary and the hospital to see the common consequences of their carelessness. Even this cannot be totally effective if a recent report from Detroit is typical of the country at large. Here the men convicted of "speeding" were subjected to an examination by Dr. A. L. Jacoby, the city psychiatrist, before sentences were promulgated. Dr. Jacoby found that out of 17 persons convicted (all on one day!) 3 were mentally deficient. One of these, who was charged with driving at 32 miles per hour, was also deficient in hearing and sight, and could not differentiate between the "go" and "stop" signals used by the traffic controller. It is clear that only a stringent examination for the driving licence will protect the public from such dangers as this.

A Psychiatric Clinic.

A mental hygiene survey in the town of Cincinnati (Ohio) this year resulted in recommendations for a coördinated municipal effort centring in a psychiatric clinic and including the public school system, the social welfare agencies, the police courts, and the faculties of the local universities. The scheme was well supported by prominent representatives of medicine, law, and education, and as a result $30,000 a year of public money has been voted to carry it into effect. Cincinnati is the first town in this country to adopt so comprehensive a scheme.

A Health Journal for the General Public.

An important new venture is being undertaken by the American Medical Association, which is to publish a new journal of "individual and community health." *Hygeia*, as it is to be called, will be written in non-technical language, so that all may benefit from its teaching. It is understood that many prominent medical men have undertaken to contribute. The first number is promised for April, 1923.

Cancer Publicity.

As a result of the publicity organised by the American Society for the Control of Cancer during the recent "Cancer Week" no less than 2864 personal requests for information have been received by the society. Your readers are, no doubt, aware that this society seeks to combat cancer by spreading a knowledge of the predisposing causes and early symptoms of cancer, and of the importance of early diagnosis and treatment.

Public Health Services.

Reports of Medical Officers of Health: Suggestions by the Scottish Board.

THE Scottish Board of Health has issued a circular, under date Dec. 28th, 1922, to medical officers of health for Scottish burghs containing hints for increasing the usefulness of their annual reports. In cases where these reports are printed, the Board suggests that arrangements should be made for a judicious local distribution of the reports as soon as they are available, and that steps should be taken through the local press, and otherwise, to bring their contents effectively to the knowledge of the people. One of the main purposes of the compilation of the reports is recognised to be that, by giving them the widest possible publicity, they may engender a popular interest in the subject, and an enlightened public opinion to support the local authority in realising its high responsibilities for the health of its area, and in remedying, at the earliest opportunity, the various defects which the survey may bring to light. Such an increase of public knowledge and interest in these matters may also, it is suggested, become an effective means of educating the citizens in the more important conditions of public health, of warning them against particular dangers, and of securing that important coöperation and confidence between them and the health authority and its staff which is essential to successful health administration.

The annual report, it is recommended, should be concerned chiefly with the conditions affecting health in the burgh and with the means for improving those conditions. It should contain an account, brought up to the end of the year under review, of the sanitary circumstances of the burgh and of any improvement or deterioration that may have occurred during the year. Care should be taken to report fully and explicitly on injurious influences in any degree affecting or threatening to affect the public health in the burgh, and on the action that has been taken or that may still be required to combat these influences. It is of special importance that medical officers should record what action has been taken to remedy unhealthy conditions that have been referred to by them in previous reports, and that attention should be called afresh year after year to such as remain unremedied.

Report is specifically asked for from the medical officer of health on the following points:—

1. A general account of influences and conditions injurious or dangerous to the health of the burgh, and of the measures that in his opinion should be adopted for its improvement.

2. A statement of the general inquiries he has made during the year, and of any special inquiries as to sanitary matters.

3. A general statement of any matters as to which he has given advice or granted certificates, including any action as to offensive trades.

4. A specific account of the administration of the Factory and Workshop Act, 1901, in workshops and workplaces.

5. An account of any proceedings under the Housing (Scotland) Acts, 1890–1920, dealing specifically with (1) the sufficiency and habitability of working-class dwellings; (2) any schemes under consideration or contemplated for the improvement of insanitary areas under Parts I. and II. of the Housing of the Working Classes Act, 1890; and (3) the action taken where instances of overcrowding have been ascertained or suspected.

6. A statement showing whether any conditions have arisen, or are expected to arise, pointing to the expediency of a town-planning scheme for the proper control of further development.

7. An account of the presence or absence of pollution of rivers or streams in the district, the sources and nature of any such pollution, and any action taken to check it.

8. An account of any proceedings under the Burgh Police Act.

9. An account of the hospital accommodation available for persons suffering from infectious disease in general, and from small-pox in particular (including the means provided for the conveyance of such persons), and of the houses of reception, with observations on the furnishing, maintenance, administration, and adequacy of such accommodation, &c.

10. An account of the premises with necessary apparatus and attendance available for the destruction or disinfection of infected articles (including the means for the conveyance and return of such articles), also of other processes of disinfection in use, with observations on the adequacy of such arrangements and processes.

11. An account of the action taken to prevent the outbreak and spread of infectious disease.

12. A statement of any action taken (*a*) for the control of acute primary pneumonia, acute influenzal pneumonia, malaria, dysentery and trench fever, under the Public Health (Pneumonia, Malaria, Dysentery, &c.) Regulations (Scotland), 1919; and (*b*) with regard to "carriers" under the Public Health (Infectious Disease Carriers) Regulations (Scotland), 1921.

13. A statement of the facilities available for the treatment of persons suffering from venereal diseases, with recommendations as to any further measures that might usefully be taken for dealing with these diseases.

14. A statement as to the causes, origin, and distribution of diseases within the burgh, and the extent to which the same have depended on or have been influenced by conditions capable of removal or mitigation.

15. A statement of the measures adopted for the administrative control of tuberculosis, with recommendations as to any further measures that might usefully be put in force.

16. A statement of the arrangements made under the scheme of maternity service and child welfare.

17. A report on the working of the Notification of Births Act, 1907.

18. Observations on the wholesomeness of the milk produced within or imported into the district and on the general adequacy of the arrangements for the supply and distribution of milk of pure and wholesome character; also on the administration of the Dairies, Cowsheds, and Milkshops Orders and the Milk (Scotland) Order, 1921; and any action taken as to tuberculous milk, whether under local Acts or under the Dairies, Cowsheds, and Milkshops Orders.

19. An account of the work done under the existing arrangements for the inspection of meat at slaughter-houses, shops, and elsewhere: observations on unsound food, food inspection, and the sanitary condition of premises where foods are manufactured, prepared, stored, or exposed for sale, indicating any important respects in which existing

powers have been found inadequate for dealing with insanitary conditions in such places.

20. A report on the work done by the local authority under the Sale of Food and Drugs Acts, and under the Sale of Food Order, 1921, with observations on any special questions which have received or require attention.

21. A tabular statement, in such form as the Board may direct, (1) of the cases of infectious disease notified in the burgh, and (2) of the infantile mortality in the burgh.

The medical officer of health is asked to transmit a copy of his report to the Board and to the local authority not later than April 30th, and he is reminded that report must be made to the Board, with the least possible delay, of every case of ophthalmia neonatorum in which, in his opinion, there occurs appreciable loss of vision.

A SURVEY OF PUBLIC HEALTH IN SOUTH AFRICA.

UNDER the title of the Public Ill-Health, Dr. J. A. Mitchell, secretary for public health and chief health officer to the Union of South Africa, delivered a stimulating address to the recent South African Medical Congress at Johannesburg. His frank review of failures is not merely of local interest and we summarise, as closely as possible in Dr. Mitchell's own words, some of the features which he finds disquieting in the public health of the Union.

First, he mentions the overcrowding and insanitary housing of a considerable section of the population, both European and native. Many of the smaller towns and villages have polluted water-supplies, leading to a prevalence of worms and intestinal diseases. In many centres tuberculosis is a serious scourge. Malaria is prevalent and is retarding the development of a large part of the Transvaal, Zululand, and the northern coastal belt of Natal, comprising the most fertile districts. The death-rate of the Union is descreditable. The infantile mortality among Europeans in the Union is twice as high as it should be ; in some places it could be halved, in others it could be reduced to a third of the present rate. There is widespread ignorance and carelessness as regards health matters, including the care of infants and children and the feeding both of children and adults, while little is being done to enlighten the rising generation in these matters. Very few are short of food, but a considerable proportion eat too much for the work they do, and still more eat the wrong kind of food or do not cook it in the right way. School medical inspectors report that malnutrition is common, even in the children of the well-to-do. Children are fed on sloppy food, requiring no mastication, resulting in decayed teeth and ill-developed jaws. Attending football matches, &c., is more popular than participation in games. There is much use of patent nostrums and "Dutch" medicines. There is a great dearth of competent maternity nurses, and an enormous consequent loss of infant and maternal life. The people as a whole are too extravagant and pleasure loving. The Union, with a white population of 1,500,000 and an annual government expenditure of £29,000,000, spent in 1920 £900,000 on bioscopes and entertainments, and £11,000,000 on liquor. There is a growing disinclination in both sexes for the ties and responsibilities of marriage. The average age at marriage is increasing and so is the divorce rate. In Johannesburg the annual number of divorces is more than one-third of the marriages. Large families are out of fashion and birth control is on the increase. A type of female—more or less of the neuter gender—is increasingly common ; she does not marry, or if she does, she proves sterile or takes care to have no children, or at most one or two, and these she brings up on the bottle. Were this state of things to continue and increase, says Dr. Mitchell, the prospect of building up a strong white nation in South Africa would be gloomy indeed.

Fortunately, however, there is another side to the picture. In recent years, and especially since the influenza epidemic, all responsible authorities have been devoting more attention to health matters. The public press is lending a hand. Religious organisations are realising that they cannot hope to survive on dogma, ritual, and abstractions, and that mankind to-day requires a practical religion applied to the current problems of life. The boy-scout and girl-guide movements have beneficial and far-reaching effects. The Red Cross is doing good peace work. The thinking and intelligent section of the public is waking up. The crying need of to-day is for more knowledge, for a return to simpler habits of life, for a truer appreciation of the things that really matter, and for better organisation.

Dr. Mitchell passes on to ask what the medical profession is doing in connexion with these matters. In civilised countries to a large extent advancement in the public health depends upon the knowledge and effort of the individual. "Is the medical profession in South Africa playing the part it could and should play in diffusing that knowledge and awakening that sense of responsibility ?" asks Dr. Mitchell, and he goes on to say "that some means should be devised of giving the private practitioner a live, real, and financial interest in prevention." He is not in favour of a State medical service free to all. He realises that specialist assistance must be brought within reach of all and regards the Dawson report as an excellent basis for discussion. He concludes by a reference to the profit made by the Metropolitan Life Assurance Company of New York by the system, instituted in 1914, of free periodical medical examination and advice for their policy-holders.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdrs. to be Surg. Capts : R. J. MacKeown (*Vernon*), F. H. Nimmo (*Victory*), R. F. Clark (*Vivid*), and R. St. G. S. Bond (R.N. College, Greenwich).

Surg. Lt. K. A. I. Mackenzie to be Surg. Lt.-Comdr.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt.-Comdr. R. Wilbond to be Surg. Comdr.

Hon. Surg. Lt.-Comdr. F. J. Hannan to be Hon. Surg. Comdr.

ROYAL ARMY MEDICAL CORPS.

Col. R. J. Blackham, late R.A.M.C., is placed on half pay.

The undermentioned Lt.-Cols., from R.A.M.C., to be Cols. : Bt. Col. R. S. Hannay, vice Col. A. H. Morris (ret. pay) ; (Temp. Col.) H. P. W. Barrow, vice Col. R. J. Blackham.

Lt.-Col. G. B. Riddick retires on ret. pay.

Lt.-Col. G. M. Goldsmith relinquishes the temp. rank of Col.

Capt. and Bt. Maj. L. G. Bourdillon retires, receiving a gratuity, and is granted the rank of Maj.

Capt. A. E. Drynan resigns his commn.

ARMY RESERVE OF OFFICERS.

The undermentioned cease to belong to the Res. of Off. on account of physical unfitness : Lt.-Cols. J. P. Silver, C. S. Smith, W. F. H. Vaughan, F. S. Walker, M. C. Wetherell, and A. H. O. Young ; Majs. W. M. Power, (Bt. Lt.-Col.) G. F. Sheehan, and F. T. Turner.

Lt.-Col. W. Owen-Prichard, late E. Afr. Med. Serv., to be Lt.-Col.

ARMY DENTAL CORPS.

Capt. U. J. G. Dancer, late Spec. List, to be Capt.

TERRITORIAL ARMY.

Maj. L. D. Bailey to be Lt.-Col., and to commd. the Co. of Lond. Fd. Amb.

Capt. R. S. Taylor resigns his commn. and retains the rank of Capt.

General Hospitals : The undermentioned, having attained the age limit, are retired and retain their rank except where otherwise stated : Lt.-Cols. G. E. Wherry, F. Deighton, E. Hobhouse, R. F. Jowers, E. F. Maynard, and F. J. Paley ; Majs. A. Cooke (granted the rank of Lt.-Col.), E. L. Jones, J. A. Wright, W. Broadbent, C. F. Bailey, T. H. Ionides, F. G. Bushnell, and W. A. Bowring ; Capts. (Bt. Maj.) J. F. Fawcett and (Bt. Maj.) A W. Ormond ; Capts. J. Gutch, G. S. Haynes (granted the rank of Maj.), P. N. B Odgers, H. W. G. Mackenzie, H. G. Turney, W. S. Colman, R. P. Rowlands, R. J. Probyn-Williams, M. Horne, H. F. ancaster, and F. D. S. Jackson (granted the rank of Maj.).

L

The undermentioned relinquish their commns. and retain their rank, except where otherwise stated: Maj. R. A. Milligan; Capts. J. Young (granted the rank of Lt.-Col.), J. G. Morgan (granted the rank of Maj.), H. B. Pope (granted the rank of Maj.), A. G. Banks, H. M. McC. Coombs, H. E. Roaf, J. B. Kelly, J. P. Mathews, W. Sharrard, J. E. Dunbar, A. C. McMaster, J. Lloyd, and G. I. Strachan.

Sanitary Companies: Capts. (Bt. Maj.) C. C. Frye, (Bt. Maj.) G. W. Ellis, E. C. Sprawson, E. A. Cooper, C. J. D. Gair, R. Robison, J. E. Wilson, C. E. C. Ferry, N. A. Dore, M. Greenwood, P. Hartley, G. L. Matthews, E. R. Matthews, W. Buddin, S. A. Mann, J. Davidson, J. Tate, F. E. W. Rogers (granted the rank of Maj.), A. F. Girvan, J. Griffiths, A. C. Bescoby, M. Wilson, R. W. E. Stickings, A. T. Cameron, R. L. Collett, J. S. Arthur, A. E. Woodhead, J. D. Davidson, A. R. Muirhead, R. K. Ellison, T. McL. Ormiston, F. J. E. China, L. Hawkes, W. V. Barritt, G. Bryce, R. T. Pearl, J. Waterston, J. Jackson, J. P. M. Dowdall, W. E. Evans, L. H. Callendar, R. S. Moon, A. G. Harrington, D. Williams, A. G. Yates, F. G. Caesar, S. C. Rigg, W. D. Dick, R. Wood, J. Buckland, W. H. S. Dunn, P. R. Fincher, T. W. Wheeler, W. G. Gibb, I. E. Macdonald, L. N. Duguid, F. C. Cook, F. Rae, J. Clayton, J. H. N. Price, K. MacLennan, A. E. Rayner, E. J. Messent, T. J. Murray, O. Cattlin, P. E. Lander, R. H. Murray, H. J. L. Barefoot, B. R. Hebblethwaite, M. S. Briggs, E. B. Argles, H. Vickers, T. Legge, A. E. Jury, J. A. Andrews, W. J. Read, H. L. Farmer, J. W. Hoflin, J. Pinder, K. S. Beken, A. D. Peacock, M. Canton, C. W. Yates, J. W. Munro, A. C. Swanston-Thomas, R. McKenzie, B. Chaikin, T. H. Savory, J. Dall, A. Sykes, W. Simpson (granted the rank of Lt.-Col.), L. A. Dingley (granted the rank of Maj.),A. C. Hepburn (granted the rank of Maj.), H. A. Higginson, O. Cook, A. Sutcliffe, C. R. Wallace, G. F. Rogers, H. Head, A. G. Atkinson, C. P. Matthews, W. S. H. Campbell, F. N. McRae, D. M. Neil, G. T. P. Tatham, L. Lloyd, G. M. Till, C. J. Regan, F. Evans, I. Walker, P. G. MacGregor, and S. Shaw; Lts. R. B. Driscoll, E. Jones, E. F. White, H. H. Clay, W. W. Earwaker, J. G. Seppelt, A. Hurd, B. Davies, and L. F. Wallis.

TERRITORIAL ARMY RESERVE.

The undermentioned relinquish their commns. and retain their rank, except where otherwise stated: Capts. E. B. Hinde (granted the rank of Maj.), J. A. Innes, D. W. Hardy, A. C. Hincks, C. W. Ellison, J. P. Elias, and J. M. O'Meara.

Maj. F. W. Burton-Fanning, having attained the age limit, is retired, and is granted the rank of Lt.-Col.

Maj. T. R. Bradshaw, having attained the age limit, is retired, and retains the rank of Maj.

Capt. W. Tyson, having attained the age limit, is retired, and is granted the rank of Maj.

Capts. J. Anderson, C. Cooke, and F. Phillips resign their commns. and retain their rank.

Sanitary Companies: The undermentioned, having attained the age limit, are retired, and retain their rank except where otherwise stated: Maj. C. E. Goddard; Capts. H. S. Fremlin (granted the rank of Maj.), C. G. Moor, L. W. Hignett, G. N. F. Reddan, W. F. Corfield (granted the rank of Maj.), N. Gibbie, R. A. Askins, D. H. Burleigh, and A. H. Hasnip.

The undermentioned, having attained the age limit, are retired, and retain their rank: Majs. H. N. Goode, D. P. M. Farquharson, J. Teare, and C. A. Spooner; Capt. (Bt. Maj.) H. Brian-Pearson; Capts. J. O. W. Barratt, J. Golding, and M. Priest.

ROYAL AIR FORCE.

Wing Commanders to be Group Captains: H. Cooper and M. W. Flack.

Squadron Leader to be Wing Commander: H. E. Whittingham.

Flight Lieutenants to be Squadron Leaders: J. M. A. Costello, J. H. Wood, and A. J. Brown.

INDIA AND THE INDIAN MEDICAL SERVICE.

Maj. Norman White has been charged with an important investigation in the East by the Health Organisation of the League of Nations. The services of Capt. C. J. L. Patch have been placed at the disposal of the Punjab Government temporarily. Majs. H. H. King and H. E. Shortt, Brevet-Maj. J. A. Sinton, Capt. G. C. Maitra, Dr. K. S. Mhaskar, and Capt. R. H. Malone have been appointed to the Medical Research Department, the last-named only temporarily. The Governor of the Punjab has appointed Lt.-Col. D. M. Davidson to be a member of the Punjab Legislative Council in the vacancy caused by the resignation of Col. R. C. Macwatt. Lt.-Col. W. M. Houston, health officer of the Port of Bombay, has been granted leave for a year. Lt.-Col. W. C. H. Forster has been appointed a member of the Punjab Legislative Council. Maj. E. H. M. Moore has been appointed Civil Medical Officer of Ranikhet; and Maj. W. L. Forsyth has been temporarily posted to the Punjab.

Correspondence.

"Audi alteram partem."

A CENTENNIAL YEAR.

To the Editor of THE LANCET.

DEAR SPRIGGE,—I am reminded that THE LANCET has entered upon its hundredth year and will doubtless celebrate its centenary in some form or another next October.

I can remember the Jubilee Dinner which took place at "The Ship," Greenwich, and I wonder if there are any survivors who were present at that dinner besides myself. Of those who were present, I seem to have retained the strongest impression of Dr. Steele and Mr. Potter, the lawyer. I remember Steele proposed the health of the lawyer, and that his address was full of classical allusions to Themis, &c., and that Mr. Potter made a happy reply.

It is 51 years since my first clinical communication was published in THE LANCET. I was unqualified, but was a Clinical Assistant at the Royal London Ophthalmic Hospital at the time, and the article was entitled A Visible Striation of the Normal Crystalline Lens, and was accompanied with drawings representing enlarged views of the stellate lines on the front of the lenses in one of the cases.

Wishing you a happy and prosperous New Year.

Believe me, yours sincerely,
Dec. 28th, 1922. JOHN TWEEDY.

*** This personal letter to the Editor is published by permission. Sir John Tweedy actually assisted the staff of THE LANCET before he was qualified, although he was not openly appointed until he had obtained a medical qualification. But later and for 13 years he remained in the closest connexion with the editorial department of the paper, and it was perfectly well known that, during the long illness of Dr. James Wakley, which culminated in his death in 1886, he was largely responsible for the conduct of this journal. Mr. Potter was a member of the firm of Pownall and Fairthorne, one of the partners in which was a connexion of the Wakley family. The firm came to the legal assistance of THE LANCET at the birth of the paper, and continued, under different styles, to act for THE LANCET for upwards of 80 years. Dr. James Peddie Steele, who died five years ago, at the advanced age of 81, had then been a member of the staff of THE LANCET for 50 years. He was a famous Latin scholar, and had made his mark as a classic before he graduated in medicine. In middle life he went to Rome, being connected with several Italian families, and in that city he was known to many British scholars and medical men and became a personal friend of the leaders of Italian scientific and social thought. From Rome, and later from Florence, he continued to write occasionally for THE LANCET until the end of his life.—ED. L.

THE PREVENTION OF DISEASE.

To the Editor of THE LANCET.

SIR,—Our national progress in the prevention of death has been much more than it might, if perhaps less than it ought to, have been. With infantile mortalities round about 80 and city and county death-rates of 11 or 12, the general appetite has been whetted for more. The medical schools have been urged to pay more attention to teaching the prevention of disease, and there is popular feeling going abroad that the real business of the doctor may after all be to keep people healthy rather than to cure them when they are sick. It seems almost churlish to examine so admirable a proposition too closely; general enthusiasm and a will to succeed will achieve much and more than they have already done, but it is probably as well to reflect briefly on what we mean by the "prevention of disease." Typhoid fever can be prevented by keeping the typhoid bacillus away from man, rabies by similarly segregating mad dogs, small-pox by universal and repeated vaccinations, lead-poisoning by prohibition of lead. And the dramatic triumphs of this sort which have been reached show everyone plainly enough that they are to be repeated in other fields by a knowledge of causation. And with this appreciation of the importance of the discovery of causes there is apt to grow up an impression that the "prevention of disease" is fundamentally and primarily a search for causes, and that it can be promoted in no other way than by their identification and a practical application of the information obtained.

In a perfect world inhabited by none but perfect medical men this would no doubt be about all there is to say about an obvious truth. But it is suggested that this particular piece of truth is regarded as too absolute in those parts of the actual world which most nearly approach this sort of perfection, and that our teaching schools are apt to neglect another side of preventive medicine of no less importance. There is, in fact, a common confusion about the meaning of "disease." To the trained medical man who has no nonconformist ideals "disease" means a state where some part or parts of the body are altered in structure or function or both. There may be some difficulty in deciding whether alteration is present or not, but by this way of thinking a man with a granular kidney is certainly "diseased." To the patient, on the other hand, "disease" means simply feeling ill or inefficient as a whole or in parts, and from his own point of view the man with the granular kidney may not be diseased at all. In the medico-pathological sense everyone is more or less diseased by the time middle age is reached; atrophies, fibroses, and such like are certainly unpreventable in themselves and almost always incurable. With all respect to the prevalent cult of youth, middle-aged people are of some importance in the world, and one of the most useful aspects of the "prevention of disease" consists in helping their deteriorated bodies round the difficult corners and finding out how best they can adjust the small things of daily life in such a way that the "disease," objectively inferred by the doctor from his point of view, ceases to exist from the point of view of the patient.

This sort of prevention has nothing to do with ultimate causes and can be pursued with success in ignorance of them. It is the prevention which suggests the periodical medical examination of grown-up people and is justified by the results of such inquiries. Its systematic exploitation is, in comparison with the search for causes, sadly neglected. But in a working world the prevention of consequences and symptoms is one of the great charges on medicine, and the prevention of disease will make better progress if it is openly recognised that it has its symptomatic as well as its ætiological aspect.

I am, Sir, yours faithfully,

Jan. 1st, 1923. A Pathologist.

THE UNIVERSALITY OF APPENDICITIS AND CANCER.

To the Editor of The Lancet.

Sir,—"The meat consumption of the world has been going up by leaps and bounds, and the number of cases of appendicitis and cancer has increased pari passu: hence the universality of the two diseases." In these words Dr. G. A. Casalis de Pury concludes his letter to The Lancet (Dec. 30th, 1922) on the above subject. Commenting on his conclusion you, Sir, justly remark, "There seems here some confusion between correlation and causation." In point of fact, modern civilised man is much less carnivorous than pre-agricultural man. I have pointed out more than once that the chief difference between the diet of neo-civilised man and primitive pre-agricultural man lies in the much larger proportion of starch and sugar it contains. Existing pre-agriculturists consume animal and vegetable food in about equal proportions, and before the discovery of cookery, which placed a large supply of starch at man's disposal, he must have been still more carnivorous.

I am not aware of any evidence that extant pre-agricultural man suffers greatly from appendicitis or cancer. Among the Esquimaux, who subsist entirely, or almost entirely, on flesh, cancer is said to be unknown. It would seem, therefore, that there is nothing distinctly provocative of either cancer or appendicitis in a highly animalised diet per se, though one can indeed conceive that animal food which has been preserved—e.g., by curing, canning, or freezing—may at times act injuriously on the alimentary canal, and so predispose to either of these diseases.

While there appears to be some evidence that certain infectious diseases (rheumatism? influenza?) are occasionally responsible for appendicitis, I have little doubt that this disease is mainly dietetic in origin—though not, I think, attributable to an excess of *sound* animal food. Dr. Casalis de Pury, in proof of his contention, refers to the absence of appendicitis "among the Bulgarian peasants who feed exclusively on vegetables and sour milk, while it is frequent among town-dwellers whose diet approaches that of cities of Western Europe"; and he dwells upon the rarity of this disease in certain continental prisons, asylums, and convents in which the diet is largely vegetarian. But does the doctor not leave out of account the effect of simplicity and regularity of meals quite apart from the proportion of animal food they contain? I venture to think that in all institutions in which the inmates are kept on a simple, regular diet appendicitis will be found to be rare. An examination of our prisons, workhouses, schools, and other institutions with regard to the frequency in them of appendicitis and cancer would, I doubt not, yield some surprising results. It is now known that the shameful condition of our jaws and teeth is due to a faulty dietary; I have advanced what I believe to be incontrovertible evidence that adenoid disease owns a like origin; and I doubt not that appendicitis is in the main similarly induced. If these contentions are sound, it is up to us to prevent an immense amount of disease by the simplest of commonsense means.

One word as to the apparent increase of cancer and appendicitis within recent years. Dr. Newton Pitt tells us that cancer has more than doubled in frequency since 1880. How far is this statistical increase to be explained by increased accuracy in diagnosis and by an increase in the proportion of people living into the cancerous age? The same authority states that appendicitis was rare until 1889 or 1890, while more than 350 cases of this disease are now admitted every year into Guy's Hospital. How far, I would ask, is this assumed increase attributable to improved methods of diagnosis? Is it not a fact that appendicitis used frequently to be diagnosed as peritonitis, and that its alleged greater frequency dates from the time when abdominal surgery, owing to the general recognition of aseptic methods, came by its own?

I am, Sir, yours faithfully,

Harry Campbell.

Wimpole-street, W., Dec. 31st, 1922.

THE BACTERIOLOGY OF OBSCURE INFECTIONS.

To the Editor of The Lancet.

Sir,—I have read with interest Dr. R. Fielding-Ould's article in The Lancet of Dec. 23rd on Some Cases of Obscure Infection, and your annotation thereon. There does not appear to be anything very obscure about these cases. The clinical data supplied, although not complete, leave little room for doubt that they were septicæmias of enteric origin. Dr. Fielding-Ould devotes much time and space to demonstrating that they were not influenza. But there seems no good ground for ever suspecting that they were influenzal in nature.

"Unfortunately it was not possible to deal adequately with the bacteriological aspect of these cases," says Dr. Fielding-Ould. Under these circumstances, it seems hardly fair to the bacteriologists to express the view, which you endorse, "that bacteriology in this connexion has lagged somewhat in the rear instead of taking, as it should, a rightful place in the forefront of the battle." There is no field of medicine which has been tilled with greater assiduity and success by bacteriologists—chiefly workers in the Royal Army Medical Corps. If Dr. Fielding-Ould will consult some of the pre-war numbers of the *Journal of the Royal Army Medical Corps*, he will find accounts of similar outbreaks of fever in India and elsewhere, which, for completeness and accuracy of detail, clinical, bacteriological, and serological, are models of scientific exposition.

In circumstances where hæmo-culture and bacteriological investigation of excreta and serological examination of blood cannot be undertaken useful information can be obtained by the application of Marris's atropine test. In a group of cases such as that described by Dr. Fielding-Ould, this test is capable of giving a definite answer "Yes" or "No" to the question "Are these infections of the enteric group of fevers?" It is, indeed, surprising that this simple clinical test is so little used since the war in the elucidation of obscure fever. It is not even mentioned in some of the most recent editions of standard English text-books of medicine. It takes time for the value of a discovery to be discovered.

I am, Sir, yours faithfully,
R. P. GARROW.
Health Office, Chesterfield, Dec. 26th, 1922.

JUSTIFIABLE FŒTICIDE.

To the Editor of THE LANCET.

SIR,—With reference to the letter on this subject in THE LANCET of Dec. 23rd, 1922, it can be taken for granted that no doctor will destroy a living fœtus unless he be driven to it in order to save the mother's life. Surely the authorities of the Roman Catholic Church take a short view of the matter. They apparently do not recognise that in allowing the mother to die by neglect of a craniotomy they are still not saving the child, for a dead mother means a dead unborn child. Thus there is the certainty of two deaths as against one.

While domiciliary conduct of labour continues to be in vogue, it will frequently be impossible to interfere in those extreme cases of pelvic contraction in any other way than by means of a craniotomy, unless a hospital or nursing home is available within reasonable time and distance. All this is a strong argument in favour not only of institutional treatment of labour cases, but also of antenatal care of pregnant women, whether the confinement is to take place in hospital or in the private house.

I think it may be confidently stated that adequate antenatal care of private cases is a comparatively rare thing.—I am, Sir, yours faithfully,

A. E. CHISHOLM,
Assistant Gynæcologist, Royal Infirmary, Dundee.
Dec. 28th, 1922.

THE INFECTIOUSNESS OF DIPHTHERIA: A QUESTION.

To the Editor of THE LANCET.

SIR,—A nursing association here has engaged the services of two private British nurses for a stated period of years. The nurses came out on the understanding that they should have a flat managed by themselves as their residence. The association has been unable to supply them with a private flat, and has instead given them rooms in lodgings where they live as guests.

It happens that one of the nurses has been in charge of a diphtheria case, and during the period of attendance she has several times gone to her lodgings whilst free from duty. The landlady has protested on the ground that the nurse may carry infection to the house, and the association is in favour of upholding the landlady's contention and of in future prohibiting the nurse from visiting her residence during the time she is in attendance on an infectious case. The nurse, on the other hand, argues that she has a perfect right to visit her residence, since she takes all reasonable and possible precautions against the carrying of infection, and further that she ought not to be deprived of making whatever use she likes of her leisure hours, such as the receiving of friends in her home, provided she has adopted all possible measures against the conveying of infection.

I have been asked to arbitrate between the contending parties. Can you let me know what is the rule in Britain in such circumstances, as I think that judgment in this case must be based on precedent, not on theoretical considerations?

I am, Sir, yours faithfully,
Madrid, Dec. 29th, 1922. IGNOTUS.

⁂ In case such a position should arise the original intention of providing a flat for the nurses was wise. The situation above described is practically unknown in this country, where nurses either have private lodgings or live in common with other nurses. Under the circumstances mentioned it would appear not unreasonable to ask that the nurse should not take infectious cases.—ED. L.

Obituary.

JOHN JAMES PRINGLE, M.B., C.M. EDIN., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO THE SKIN DEPARTMENT, MIDDLESEX HOSPITAL.

A WIDE circle of friends, both within and without the medical profession, will mourn the loss of Dr. Pringle, whose death at Christchurch, New Zealand, early last month, will come not altogether as a surprise.

John James Pringle was born at Lannhall, Dumfriesshire, in 1855, the third son of Andrew Pringle, of Lannhall and Borgue. Educated at Merchiston Castle School, Edinburgh, he graduated in medicine and surgery at the University of Edinburgh in 1876, continuing his studies in Dublin, Vienna, Berlin, and Paris, and taking the M.R.C.P. Lond. in 1884. Seven years later he was elected a Fellow. His first appointment was that of resident physician at the Edinburgh Royal Infirmary. After coming to London he joined the staff of the Middlesex Hospital as medical registrar 1883–84 and assistant physician 1885–95. In 1888 he was appointed physician to the skin department and lecturer on dermatology. He was also physician to the Royal Hospital for Diseases of the Chest 1884–91. During the war he became hon. consultant for skin diseases to the military hospitals in London. His help was constantly in request at meetings and congresses. He was secretary to the Dermatological Society of London for a number of years and acted as secretary-general to the Third International Congress of Dermatology held in London in 1896; at different times he presided over the Dermatological Section of the Royal Society of Medicine and of the British Medical Association. He was also a corresponding member of the Société Française de Dermatologie, of the Wiener and Berliner Dermatologische Gesellschaften, and of the Societá Italiana di Dermatologia. His contributions to dermatological literature were many and are to be found in Allbutt's System, Quain's and Fowler's dictionaries, and in special journals. He edited the well-known Portfolio of Dermochromes.

Pringle raised the dermatological department at the Middlesex to a high degree of efficiency. He was a first-rate teacher and had the faculty of creating interest in his subject among those he taught, who were attracted by the keen questioning to elicit a history, the careful and close examination of the patient, and the clear and incisive discussion of the diagnosis. Although his actual diagnosis often seemed to be almost intuitive, it was based on most careful and scrupulous observation and could always be supported by close reasoning as well as by adroit marshalling of all the facts available. Pringle had a wide knowledge of dermatological literature, an excellent memory, and a quickly acting mind; it is therefore not surprising that his opinion on rare and obscure rashes was generally accurate. He retained to the end his interest in general medicine, and he was always ready to allow how much he owed to his experience as a general physician in the out-patient department, a post he only relinquished when the increasing claims of his special work rendered it impossible for him to do the double work. It therefore came about that he played an important part in emphasising the relationship of cutaneous manifestations to abnormal conditions of the systemic functions. Great as was his interest in diagnosis, he was always helpful in suggesting treatment and his large sympathy made him a friend to his patients as well as a physician.

A friend and colleague, on whose information we have freely drawn, writes: "Pringle was a many-sided man—intellectual, a good linguist, artistic in the true sense of the word, and a good musician with a fine singing voice. Perhaps, however, his most distinguishing characteristic was his kindly personality with a real genius for friendship. To generations of students he was familiarly known as 'Jimmy,' a fact he knew and was proud of in his heart. To anyone in trouble he was a kindly comforter and a generous friend. For years he paid a daily visit to cheer and interest a former senior colleague in his old age and infirmity. A Bohemian friend of his younger days, fallen on evil times and neglected by nearly all, found in Pringle's house asylum, nursing and comfort in his last illness. Such instances could be multiplied indefinitely, save that these kindly acts were done almost by stealth."

Of Dr. Pringle's services to dermatology another colleague writes: "Pringle was one of those who helped to bring dermatology into the position it now holds as an important branch of scientific and practical medicine. He was an active member of the Dermatological Society of London from soon after its foundation in 1882; he was editor of the *British Journal of Dermatology* in the period of its infancy; his zealous inspiration of those who took part in the London International Conference of 1896 led to one of the most successful congresses that have been held, and he was always justifiably proud of the volume of transactions which remain as a monument of his energy and enthusiasm. Although not an active worker in pathological research he was ever alive to all that was being accomplished or attempted in this field. Ichthyosis, Darier's disease, affections of the pigmentary system, and of the sweat glands and sebaceous glands, interested him, and his pioneer papers in this country on adenoma sebaceum, Pringle's seborrhœid and angiokeratoma will be remembered. Of his personal characteristics it may be said that he was accurate, precise, and punctilious in everything; in his work, in his speech and deportment, his household surroundings, his writings, and his management of a dermatological meeting. He was a skilled linguist, a lover of music, and an accomplished singer."

It was evident to all Dr. Pringle's friends that in recent years he had suffered greatly. It is not too much to say that during the war his work verged on the heroic. In spite of great pain and discomfort, often forcing him to take to his bed, he insisted on doing his full hospital work, and in addition he attended at the military hospital at Millbank. It was characteristic of him that he never allowed private work or personal discomfort or inconvenience to interfere with his hospital duties. It was hoped that the voyage to New Zealand and the change of scene might restore him to some degree of comfort and health, but the hope was futile.

Medical News.

Society of Apothecaries of London.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—D. D. Anderson, St. Bart.'s Hosp.; G. K. Butterworth, St. Mary's Hosp.; E. M. Chidson, Royal Free Hosp.; H. Hirst, Manchester; G. Rothaus, Geneva and Charing Cross Hosp.; R. A. Walker, St. Thomas's Hosp.; and A. Weinger, King's Coll. Hosp.

Medicine.—D. D. Anderson, St. Bart.'s Hosp.; G. K. Butterworth, St. Mary's Hosp.; E. M. Chidson, Royal Free Hosp.; L. A. Daly (Sect. I.), St. Bart.'s Hosp.; S. Douglas, Univ. Coll. Hosp.; D. J. Dubash, Bombay and Royal Free Hosp.; M. P. Parker (Sec. II.), Royal Free and St. Mary's Hosp.; P. D. Richards, St. Bart.'s Hosp.; and S. W. Turtle (Sec. I.), London Hosp.

Forensic Medicine.—A. H. Allam, St. Mary's Hosp.; D. D. Anderson and L. A. Daly, St. Bart.'s Hosp.; and M. P. Parker, Royal Free and St. Mary's Hosps.

Midwifery.—D. D. Anderson and B. Dous, St. Bart.'s Hosp.; S. E. Hymans de Tiel, Royal Free Hosp.; and C. F. Parry, Guy's Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: D. D. Anderson, E. M. Chidson, B. Dous, D. J. Dubash, C. F. Parry, P. D. Richards, G. Rothaus, and A. Weinger.

University of St. Andrews.—At recent examinations the following candidates passed in the subjects indicated:—

THIRD PROFESSIONAL EXAMINATION FOR M.B., CH.B. DEGREES.

Forensic Medicine.—Fakherddin El Ahmadi, Cecil B. Armit, Thomas F. Black, Robert Blair, William R. C. Campbell, Robert H. Craig, William Cunningham, John W. A. Dennis, Thomas A. Doran, Lewis Farrell, Douglas R. Ferens, Harold J. Fraser, Charles H. S. Gowdie, Jodh Singh Guruwara, James A. G. Keddie, Lutfur Rehman Khan, James M. A. Lowson, Alexander K. McCowan, John C. MacMillan, Douglas F. Menzies, John R. Murray, David Myles, George Napier, Donald M. Ross, Benjamin W. Rycroft, Jainti Dass Saggar, Alexander Shand, James D. Sinclair, Duncan Stewart, Charles F. Swinton, and John Wilson.

Public Health.—Fakherddin El Ahmadi, Cecil B. Armit, Thomas F. Black, Robert Blair, William R. C. Campbell, Thomas Christie, Robert H. Craig, William Cunningham, John W. A. Dennis, Thomas A. Doran, George A. Dunlop, Lewis Farrell, Douglas R. Ferens, Harold J. Fraser, Charles H. S. Gowdie, James M. A. Lowson, Alexander K. McCowan, John C. MacMillan, Douglas F. Menzies, David Myles, George Napier, John Petrie, Donald M. Ross, Benjamin W. Rycroft, Jainti Dass Saggar, Alexander Shand, James D. Sinclair, Ram Parshad Sood, Duncan Stewart, Charles F. Swinton, and John Wilson.

FOURTH PROFESSIONAL EXAMINATION FOR M.B., CH.B. DEGREES.

Medicine.—James Craigie, Jean M. Davidson, Harry Fisher, Penuel G. Grant, Sydney S. Ogilvie, John E. Overstead, Nora A. M. Rodger, Blanche D. S. Spence, William A. Steel, Arthur K. Tateson, William Thomson, and Thomas Wilson.

Surgery.—William S. D. Elder, Ruby N. Foggie, Penuel G. Grant, Charles R. Henderson, Mary M. Jack, Nora M. Lindberg, Gracie M. McRorie, Jean H. Morton, Janet L. A. Muirhead, Sydney S. Ogilvie, Alexander B. Richardson, Nora A. M. Rodger, Jamiat Singh, Janet O. Stephen, and William Thomson.

Midwifery.—David A. K. Cassells, Charles R. Henderson, Sydney S. Ogilvie, Blanche D. S. Spence, Janet O. Stephen, William Thomson, and Thomas Wilson.

University of Dublin, School of Physic, Trinity College.—At examinations held recently the following candidates were successful:—

FINAL MEDICAL EXAMINATIONS.

Part II., Medicine.—Reginald Hegy, Robert H. Micks, James O'Neill McKenna, Louis J. Coetzee, Bernard Gluck, Cecil G. S. van Heyningen, Asher Asherson, Norman E. H. P. Williams, Douwe Marinus Vellema, Thomas G. Wilson, Arthur Darlington, Cecil W. R. McCaldin, Francis B. D'Arcy, John C. Earl, Ernest M. Landau, Cecil A. V. Ovendale, William E. Holmes, Florine Isabel Irwin, Jan Hendrik Hodgman, Philipp F. H. Wagner, Lazarus Heyman, Alexander Bernstein, Siegfried D. Gabbe, Reuben Lipschitz, Harold Renton, Robert L. C. Fisher, Charles Gordon, Percy Samolsky, Louis Harris, David S. Spence, Hugh R. Brady, Henry L. Hanna, James R. Wills, Rupert L. Hill, John Kalmanson, Maurice Schwartzberg, Joseph E. Deane, Frederick W. G. Smith, Jacobus F. van Staden, Albert E. O'Donnell, Nicolass Jan Valkenburg van Druten, Alice E. Dockrell, Tobias Freedman, and Barend Vivier.

Surgery.—Bernard Gluck (passed on high marks), David J. Malan, James O'Neill McKenna, Isidore P. Myers, Louis J. Coetzee, Douwe Marinus Vellema, Michael G. J. Powell, Robert R. Baker, Ruth Lemon, Percy Samolsky, Charles E. Brunton, John B. Moran, Charlotte A. Stuart, Cecil G. S. van Heyningen, Max Wulfsohn, William E. Callanan, William E. Holmes, Harry C. Dundon, Paul J. Grobler, Robert A. O'Meara, Samuel M. Geffen, Mary H. Harcourt, Albert E. O'Donnell, Reginald R. J. Brandt, Victor Robinson, Maurice Schwartzberg, Michael Gallivan, John Kalmanson, John D. Wicht, and Albertus W. Eksteen.

Midwifery.—John M. Mounsey, Paul J. Grobler, Reginald R. J. Brandt, and Ely G. Copeland (passed on high marks), William R. Fearon, Benjamin W. D. Fayle, Francis J. O'Meara, Etienne Rodolphe Hafner, Henry W. L. Dale, Francis C. B. L. B. Crawford, Wilfrid E. C. Wynne, William S. Dixon, Reginald A. Dench, Arthur Darlington, Henry M. Martin, Albert V. Foster, Joseph A. Gayner, Harold Lewin, Agnes McLaughlin, Bernard Morris, Richard A. D. Pope, Harold Renton, George F. T. Saunders, Margaret L. Cowan, Anne D. Dockrell, Hans J. Hugo, Robert T. Jackson, Jack A. Levett, Cecil A. V. Ovendale, Samuel W. Jamison, Victor O. McCormick, William B. E. McCrea, Marjorie F. Sibthorpe, Charles T. MacCarthy, Hyman S. Roseman, Hugh R. Brady, Eileen A. Boyd, and William E. Hutchinson.

Harveian Society.—The annual general meeting of the Harveian Society will be held at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, on Thursday, Jan. 11th, at 8.15 P.M., when the election of officers for the forthcoming year will take place, and the President, Sir William Willcox, will give an address. A smoking concert will be held at the end of the meeting.

The late Dr. E. V. Gostling.—Ernest Victor Gostling, M.R.C.S. Eng., who died at Felixstowe on Dec. 30th, 1922, aged 50, qualified from St. Thomas's Hospital in 1900, having previously graduated in arts at Caius College, Cambridge, where he also distinguished himself as an athlete. After qualifying he became house surgeon at the Royal Infirmary, Derby, and later held the post of house physician at Addenbrooke's Hospital, Cambridge. As commander of the East Anglian Field Ambulance he was at the first landing at Suvla Bay, where he was wounded and gained the D.S.O. He afterwards became assistant director of medical service, retiring from the Territorial Service in 1919 with the rank of Lieut.-Colonel.

Royal Society of Arts.—Among the lectures to be delivered at the house of the Society, 1, John-street, Adelphi, London, W.C. 2, during January are the following: On Jan. 17th, at 3 P.M., Mr. C. A. Klein will speak on Hygienic Methods in Painting—the Damp Rubbing Down Process, Dr. T. M. Legge presiding. On Jan. 24th, at 8 P.M., Sir William Bragg, F.R.S., will deliver the "Trueman Wood" Lecture on the New Methods of Crystal Analysis, and their Bearing on Pure and Applied Science, Mr. Alan Swinton, F.R.S., presiding. On Jan. 31st, at 8 P.M., Mr. T. H. Fairbrother and Dr. A. Renshaw will discuss the Relation Between Chemical and Antiseptic Action in the Coal Tar Dyes.

The late Sir Francis Farmer.—The death occurred suddenly on Dec. 24th, 1922, of Sir Francis Farmer, L.D.S. R.C.S., who qualified in dental surgery in 1894 from the National Dental and Middlesex Hospitals, subsequently holding the post of house surgeon at the first named. He then became dental surgeon to St. Edward's School, Totteridge, and later to the London Hospital, holding the appointment of lecturer in dental surgery and pathology at the London Hospital Medical College. At the time of his death he was consulting dental surgeon to the London Hospital and to the Queen's Facial Hospital, Sidcup, where he had done excellent plastic surgery. In 1902 Sir Francis Farmer received a presentation from the Secretary of State for War in recognition of his services, and in 1916 he received the honour of knighthood. His numerous publications were mainly concerned with plastic surgery of the face and jaw.

International Congress of Ophthalmology (1925).—At the International Congress of Ophthalmology held in Washington in April, 1922, Mr. Treacher Collins presented an invitation on behalf of all the ophthalmological societies of Great Britain and Ireland to hold the next congress in London in the year 1925. The invitation was accepted on the motion of Prof. Gullstrand, of Upsala, Sweden, seconded by Dr. Lucien Howe, of Buffalo, New York. A general committee consisting of representatives of the inviting societies has since met and has formed an executive committee, empowered to make arrangements for the 1925 congress. It is to be held in London during the four days, Tuesday, 21st, to Friday, July 24th. The three official languages are to be English, French, and German. The subscription for membership has been fixed at the sum of £2. Invitations will be sent to the principal ophthalmological societies or other representative bodies in every nation, asking them each to nominate a delegate to the congress who would be responsible for promoting its interests in the country which he represents, so as to endeavour to make it a great reunion of all those interested in ophthalmology throughout the world. In the preliminary notice of the Congress the Executive Committee is given as follows: Mr. E. Treacher Collins, chairman; Mr. J. Herbert Fisher, vice-chairman; Mr. Ernest Clarke, treasurer; Mr. Leslie Paton, 29, Harley-street, London, W., and Mr. R. R. James, 46, Wimpole-street, London, W., secretaries; Mr. A. B. Cridland, Mr. J. B. Lawford, Mr. Humphrey Neame, Sir John H. Parsons, F.R.S., Mr. A. H. H. Sinclair.

Frances Wood Memorial Prize.—The Council of the Royal Statistical Society will, in November, 1923, award this prize, value £30, for the best investigation of any problem dealing with the economic or social conditions of the wage-earning classes. Undergraduates or graduates of not more than three years standing of universities in the United Kingdom are eligible to compete. Essays are to be sent to the Hon. Secretaries of the Royal Statistical Society, 9, Adelphi-terrace, London, W.C. 2, not later than July 1st.

Unemployment Relief and Hospital Repairs.—A memorandum has been sent to the Government by King Edward's Hospital Fund for London suggesting that when public funds are being allocated to provide work for the unemployed, consideration should be given to schemes for hospital additions, alterations, and repairs. The Fund has been unable to make grants for this purpose in 1922 except in cases of great urgency, since maintenance grants take up so much of the money at its disposal.

The Guild of SS. Luke, Cosmas, and Damian. This guild, which was established in 1900, aims at facilitating intercourse between Catholic members of the medical profession and cognate branches, and the clergy throughout the British Empire, for the study and discussion of medico-religious questions. The President is Dr. Ernest E. Ware and the hon. secretary Dr. William J. O'Donovan, 30, New Cavendish-street, London. A new quarterly organ, entitled "The Catholic Medical Guardian," is being published by the guild; the first number will shortly be issued.

The late Dr. Herbert Ashley Gaitskell.—Dr. H. A. Gaitskell, who died at Westcliff-on-Sea on Jan. 1st, received his medical education at Cambridge University and Guy's Hospital, London. He graduated M.A. in 1898, M.B., B.C. in 1899, and M.D. in 1902. Among his past appointments were those of house surgeon at the Warneford Hospital, Leamington, and deputy medical officer of H.M. Prison, Northampton. He was ophthalmic surgeon to the Victoria Hospital, Southend, and to the Southend Corporation Children's Eye Clinic. Dr. Gaitskell was an occasional contributor to the columns of THE LANCET.

Central Midwives Board.—A novel and interesting case came up at a recent penal session of the Board. The senior sister at a hospital approved for training midwives was cited to appear under the following circumstances. A patient who had previously lost two premature children was in the second stage of labour, the os fully dilated, the head in sight, the pains inefficient, and the fœtal heart sounds such as to suggest that the child's life was in danger. The sister telephoned for the salaried medical officer who was in the habit of attending whenever medical assistance was required. Unable to come just then, he instructed the sister to administer a little ether and to lift the head over the perineum with forceps; this was done with complete success, a living child being easily delivered. The patient's husband, however, lodged a complaint on the grounds that an anæsthetic had been administered and forceps applied without the presence of a qualified medical practitioner. Counsel for the Board stated that the matter was one which had not previously formed the subject of a decision or judgment by the Board. He submitted that the practice was improper in law, inasmuch as if some one other than a doctor used an anæsthetic or forceps and disaster resulted, legal immunity did not exist and indictment for damages or manslaughter might follow. According to the rules, an emergency arose when the doctor who was summoned was unable to come, and the midwife should have sent for another doctor. Counsel for the defendant submitted that in an emergency the sister had acted correctly in carrying out the doctor's instructions with, as it turned out, complete success. It was nowhere forbidden in the rules that a midwife should give an anæsthetic or use forceps, and no statute or regulation had been broken. After prolonged deliberation Sir Francis Champneys announced that as regards the midwife the Board was unwilling to use the word "misconduct" and the case was dismissed. On any subsequent occasion, he added, it would not be permissible, however, to allege exceptional circumstances. It was no part of a midwife's ordinary duty to do such things otherwise than in the presence of a medical practitioner. The chief responsibility rested upon the authorities of the hospital who ought to have tried to get some other medical man or woman. The Board felt for the midwife who was in a difficult position, inasmuch as the doctor had ordered her to do the work of a consultant. She had no right to feel that she was covered by the doctor; she must think of the welfare of the patient. The midwife's costs were refused on the ground that payment of costs by the Board would be tantamount to admission that the midwife's conduct was not in any way open to objection.

Pasteur Centenary Dinner.—Dr. Pasteur Vallery Radot, Médécin des Hôpitaux de Paris, who is a grandson of Pasteur, will be entertained to dinner on Feb. 2nd at Vintner's Hall. H. E. le Comte de Saint Aulaire, the French Ambassador, will preside. Tickets may be obtained from Mr. André L. Simon, 24, Mark-lane, London, E.C. 3.

Medical Society of London.—A pathological meeting will be held at 11, Chandos-street, Cavendish-square, W. 1, on Monday, Jan. 8th, at 8 p.m., when specimens of interest will be exhibited.

The Prince of Wales has appointed Lord Dawson of Penn, Sir Thomas Horder, and Dr. John Weir to be Physicians in Ordinary to his Royal Highness; Lieut.-Col. Sir Hugh Rigby to be Surgeon in Ordinary; and Sir Stanley Hewett to be Surgeon-Apothecary to his Royal Highness and his Household.

Bethlem Royal Hospital.—A course of lectures and practical instruction for the Diploma in Psychological Medicine of the Universities of London, Cambridge, Durham, and others, will be given at the above hospital, commencing Jan. 15th. Syllabus and further particulars may be obtained from the Physician-Superintendent at the hospital, Lambeth-road, London, S.E. 1.

New Maternity Hospital at York.—A hospital containing 30 maternal beds, 40 cots, 6 beds for pregnant women, and 2 isolation wards, has recently been opened at York. The hospital has been adapted from a house known as Acomb Hall, and the adjoining farmhouse is being used as nurses' quarters. A scale of charges for patients who are able to pay has been laid down and it is hoped that the hospital will, to some extent, pay its way. The resident medical officer is Dr. Kathleen L. Cass and the temporary visiting surgeon is Dr. S. Louise Fraser.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, Jan. 9th.

THERAPEUTICS AND PHARMACOLOGY: at 4.30 p.m.
Discussion on "The Present Position of Organotherapy," to be opened by Prof. Swale Vincent, followed by Dr. G. R. Murray, Dr. W. Langdon Brown, and Dr. W. R. Grove.

PSYCHIATRY: at 8.30 p.m.
Paper:
Dr. Leitch Wilson: The Endocrine Factor in Mental Disease.

Thursday, Jan. 11th.

NEUROLOGY: at 8 p.m.
Clinical Evening at the National Hospital for the Paralysed and Epileptic, Queen-square, W.C.
The Hon. Secretaries will be glad if Members will send them short reports of the cases they wish to show not later than Monday, Jan. 8th.

Friday, Jan. 12th.

CLINICAL: at 5.30 p.m. (Cases at 5 p.m.)
Cases will be shown.

OPHTHALMOLOGY: at 8.30 p.m. (Cases at 8 p.m.)
Case:
Mr. J. A. Valentine will show a case of Retinitis Pigmentosa sine Pigmento.
Papers:
Mr. Harrison Butler: Some Unusual Cataract Operations.
Mr. Charles Killick: The Treatment of Conical Cornea.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Monday, Jan. 8th.—11 a.m., Mr. Maingot: Surgical Ward Cases. 12 noon, Mr. Simmonds: Applied Anatomy. 2 p.m., Mr. Addison: Surgical Wards.

Tuesday.—11 a.m., Dr. Paterson: Demonstration of Medical Cases. 12 noon, Dr. Burrell: Chest Cases. 2.30 p.m., Mr. Tyrrell Gray: Surgical Wards.

Wednesday.—10 a.m., Dr. Saunders: Medical Diseases of Children. 12 noon, Dr. Burnford: Pathological Demonstration. 2.30 p.m., Mr. Donald Armour: Surgical Wards.

Thursday.—10 a.m., Dr. Grainger Stewart: Neurological Department. 12 noon, Mr. Simmonds: Demonstration of Fractures. 2 p.m., Mr. Bishop Harman: Eye Department.

Friday.—12 noon, Dr. Flett: Radiology. 2 p.m., Mr. Banks-Davis: Diseases of Throat, Nose and Ear. 3 p.m., Mr. Sinclair: Surgical Cases.

Saturday.—9 a.m., Dr. Burnford: Bacterial Therapy. 10 a.m., Dr. Saunders: Medical Diseases of Children. 11 a.m., Mr. Maingot: Surgical Pathology.

Daily, 10 a.m. to 6 p.m., Saturdays, 10 a.m. to 1 p.m.: In-patients, Out-patients, Operations, Special Departments.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, Marylebone, W.
(Post-graduate Intensive Course in Cardiology, Jan. 8th to 20th.)

Monday, Jan. 8th.—10 a.m., Dr. J. Strickland Goodall: X Ray Examination of the Heart. 11.15 a.m., Dr. Parsons-Smith: The Anatomy of the Heart. 2 p.m., Dr. R. O. Moon: Ward Demonstration. 3 p.m., Dr. J. Strickland Goodall: Out-patients.

Tuesday.—10 a.m., Sir S. Russell-Wells: Sphygmomanometers and Arteriometers. 11.15 a.m., Dr. Hamill: The Physiology of the Circulation. 2 p.m., Dr. F. W. Price: Ward Demonstration. 3 p.m., Sir S. Russell-Wells: Out-patients.

Wednesday.—10 a.m., Dr. John Parkinson: The Polygraph. 11.15 a.m., Dr. F. W. Price: Mitral Disease. 2 p.m., Dr. H. B. Weir: Pathological Demonstration. 3 p.m., Dr. R. O. Moon: Out-patients.

Thursday.—10 a.m., Dr. John Parkinson: The Polygraph. 11.15 a.m., Sir S. Russell-Wells: Diseases of the Pericardium. 2 p.m., Dr. J. Strickland Goodall: Ward Demonstration. 3 p.m., Dr. F. W. Price: Out-patients.

Friday.—10 a.m., Dr. Parsons-Smith: The Electrocardiograph. 11.15 a.m., Dr. R. O. Moon: Prognosis in Heart Disease. 2 p.m., Dr. John Parkinson: Ward Demonstration. 3 p.m., Dr. John Parkinson: Out-patients.

Saturday.—10 a.m., Dr. P. Hamill: Ward Demonstration.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.

Thursday, Jan. 11th.—5 p.m., Dr. W. Griffith: Parasitic Diseases of the Skin.

Appointments.

Abel, A. L., M.S. Lond., F.R.C.S. Eng., has been appointed Surgical Registrar at the Cancer Hospital (Free), Fulham, S.W.

Acharya, B. G. S., M.B., C.M., L.R.C.P., F.R.C.S., D.O., Prof. of Ophthalmology, Lucknow University.

Fisher, A. G. Timbrell, M.B., Ch.B. Bristol, F.R.C.S. Eng., Assistant to the Professional Surgical Unit, University College Hospital, London.

Gross, M., M.B., B.S. Lond., Assistant Medical Officer of Health for West Suffolk.

McEvedy, P. G., M.B., B.S. Lond., F.R.C.S. Eng., Honorary Surgeon at Ancoats Hospital, Manchester.

Vacancies.

For further information refer to the advertisement columns.

Belgrave Hospital for Children, Clapham-road, S.W.—Hon. Radiologist. 50 guineas. Also Anæsthetist. 25 guineas.

Birmingham University, Faculty of Medicine.—Asst. Lecturer in Pathology. £300.

Bradford Children's Hospital.—Hon. Asst. P.

Cambridge, Addenbrooke's Hospital, John Bonnett Clinical Laboratory.—Clin. Path. £300.

Cancer Hospital (Free), Fulham-road, S.W.—Anæsthetist.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—R.M.O. £250. H.P. £125.

Derby County Mental Hospital, Mickleover.—Jun. Asst. M.O. £350.

Derbyshire Sanatorium, Walton Lane, near Chesterfield.—Asst. M.O. £300.

Dreadnought Hospital, Greenwich.—H.P. £150. Also S. for Dis. of Throat, &c.

Essex County Council and Lexden and Winstree Rural District Council.—Asst. Co. M.O.H., &c. £700.

Hamilton, Hairmyres Sanatorium and Colony.—Clin Asst. £250.

Hospital for Consumption and Diseases of the Chest, Brompton.—Asst. P. Asst. Res. M.O. £150. Also H.P.

King Edward VII. Sanatorium, Midhurst, Sussex.—Second Asst. M.O. £250.

Liverpool, David Lewis Northern Hospital.—Two H.P.'s and Four H.S.'s. Each £100.

London County Mental Hospital Service.—Seventh A.M.O. £300.

Maidstone, West Kent General Hospital.—H.S. £220.

Manchester Royal Infirmary.—Asst. M.O. £100.

National Hospital for the Paralysed and Epileptic, Queen-square, W.C.—Sen. H.P. £150.

Royal Free Hospital, Gray's Inn-road, W.C.—H.P.

St. Helens County Borough.—Asst. M.O.H. £450.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. £80.

Sheffield Royal Hospital.—H.S. to Ear, Nose, and Throat Dept. and Asst. Cas. O. £150.

South Shields, Ingham Infirmary.—Senior and Junior H.S.'s. £200 and £150 respectively.

University of London.—Univ. Chair of Anatomy. £1000.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Hon. Asst. S.

Whittingham County Mental Hospital, near Preston, Lancs.—Asst. M.O. Also Asst. M.O. Pathologist. Each £449 13*s.*

Winchester, Royal Hampshire County Hospital.—H.P. and H.S. Each £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments:—Bruton (Somerset), Okehampton (Devon), Camberley (Surrey), Torrington (Devon).

The Home Secretary gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for the Ashbourne, Bakewell, Burton-upon-Trent, Derby and Long Eaton, Ilkeston and Belper, and Wirksworth and Matlock County Courts in Circuit No. 19. Applications for the post should reach the Private Secretary, Home Office, not later than Jan. 20th.

The Home Secretary gives notice that in consequence of the resignation of Mr. T. A. McCullagh, one of the Medical Referees under the Workmen's Compensation Act, 1906, for the Bishop Auckland County Court in Circuit No. 2, the appointment held by him is vacant. Applications for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than Jan. 24th.

Births, Marriages, and Deaths.

BIRTHS.

BIGGER.—On Dec. 18th, 1922, the wife of W. G. Bigger, D.S.C., M.B., B.Ch., at Brackenhurst, Walton-on-Thames, of a daughter.

PAUL.—On Dec. 22nd, 1922, at Upper Northgate-street, Chester, the wife of Arthur Blackwell Paul, M.A., M.B., B.Ch.Cantab., of a daughter.

REID.—On Dec. 24th, 1922, at Courtfield-gardens, London, the wife of E. Lewis Reid, M.C., F.R.C.S., of a son.

SMALLWOOD.—On Dec. 22nd, 1922, at Wheathampstead, Herts, the wife of Dr. M. E. Smallwood, of a son.

SPARROW.—On Dec. 18th, 1922, at "Wayside," Watford, the wife of E. C. Sparrow, M.A., M.B., B.Ch., of a daughter.

MARRIAGES.

REID—JACKSON.—On Nov. 30th, 1922, at Ferozepore, Captain Spence Daer Reid, R.A.M.C., to Dorothy Hungerford Jackson, daughter of Mr. and Mrs. M. Hungerford Jackson, of Tudor House, Hanworth, Middlesex.

WARWICK—DALRYMPLE.—On Nov. 8th, 1922, at St. Thomas's Church, Amraoti, Berar, C.P., British India, Major Frank P. Warwick, D.S.O., I.M.S., to Una, eldest daughter of Engineer Captain John H. Dalrymple, R.N. (retired).

DEATHS.

HAYCRAFT.—On Dec. 30th, 1922, at Royston, Hertfordshire, John Berry Haycraft, M.D., D.Sc. Edin., F.R.S.E., Emeritus Professor of Physiology in the University of Wales, in his sixty-sixth year.

HOFFMAN.—On Dec. 26th, 1922, at Coombe Lodge, West-hill, Putney, Henry Westwood Hoffman, M.A., M.B. Cantab., aged 87.

NUNNELEY.—On Dec. 17th, 1922, at Bordighera, Frederick Pitcairn Nunneley, M.A., M.D. Oxon.

PICKERING.—On Dec. 19th, 1922, at George's-place, Bolton, Bernard Pickering, M.B., Ch.B., aged 41 years.

POOLE BERRY.—On Dec. 19th, 1922, at The Priory, Grantham, Harry Poole Berry, M.B., aged 63 years.

WAKLEY.—On Dec. 23rd, 1922, at Hôtel Splendide, Montreux, Switzerland, Clementina Agnes, widow of James G. Wakley, M.D.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

INDEX TO "THE LANCET," VOL. II., 1922.

THE Index and Title-page to Vol. II., 1922, which was completed with the issue of Dec. 30th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2.

Notes, Comments, and Abstracts.

THE BREAKDOWNS OF MIDDLE LIFE.[1]

BY R. FORTESCUE FOX, M.D. LOND., M.R.C.P., F.R. MET.S.

AT the beginning of my professional life I spent 20 years at a Scottish health resort, and made some studies on the action of climates, waters and baths in chronic disease. Practising to a great extent among middle-aged patients, I often found myself asking: How and when will this or that individual break down? A large number of these people were not really ill. They came for change of air and scene, and sought advice in the use of waters and baths either because they were physically or mentally out of condition, or for some ailment that had thrust itself upon them in middle life. Sometimes the slighter forms of ill-health masked the beginning of a serious breakdown. We must all sometimes wonder how it is that so many apparently vigorous persons break down 30 years before their time, whilst delicate people often go on without serious trouble until old age. I should like in this address to describe certain forms of illness in middle life that attracted my attention, and to offer some observations upon their causation and treatment.

Scope of Inquiry.

I do not refer to syphilis, malignant disease, tuberculosis or degenerative arthritis, although these are fruitful sources of illness in the middle period of life, nor yet to kidney and heart affections in the ordinary sense. What we are at present concerned with is the familiar experience of premature failure spread over many functions and organs.

The signs of an impending illness of this kind are not difficult to read. There is some distress, physical or mental. The ordinary work and play are painful and not pleasurable. Slight efforts cause exhaustion, and this abnormal fatigability can easily be recognised and measured when ordinary symptoms are absent. I suggest that all these cases have much in common, and that upon analysis they all exhibit a lowering of the normal immunity of the body (sometimes sudden and inexplicable) to the invasion of micro-organisms, an altered metabolism, a defect of elimination and consequent accumulation of waste and toxic products in the blood and tissues, associated with disordered action of the heart and abnormal blood pressures and disturbances of the nerve centres; furthermore, that with these physical changes is associated more or less mental change. In most cases some one group of symptoms is usually predominant, which sometimes leads to a narrow and misleading view of the patient's real condition. I prefer the conception of a widespread disorder of function, leading to toxæmia and ultimately to structural changes. On this common basis we can recognise typical forms, perhaps alternating with or shading into one another.

I think that after the recognition of impending breakdown the next most important thing is a study of the family history. Premature and fatal breakdowns are naturally the mark of "short-lived" families, although it is quite true that alarming breakdowns are as often as not followed by complete recovery and a normal and even extreme old age. This is exemplified by the mental disturbances and neurasthenias of middle life, and by cases of disordered action of the heart of the same epoch, apart from valvular and vascular disease. The tendency to premature vascular degeneration and apoplexy is a more serious inheritance. Many family histories show a dangerous epoch, when vascular degeneration is apt to develop rapidly. In others (often in robust persons) it is easy to trace a singular want of healthy resistance to pneumonia, enteric fever, or infections from the bowel, throat, or skin, which account for many deaths in middle life. Apart from physical tendencies, we must not forget the subconscious effect of the premature death of parents upon their children at the same age.

The following are convenient, but often provisional, labels: (1) nervous and mental disorders; (2) cardio-vascular disorders with high blood pressure; (3) gouty catarrhs; (4) glycosuria; (5) lowered resistance to specific invasions.

1. *Nervous and Mental Disorders of Middle Life.*

The onset, although generally gradual, may be quite abrupt. A strong man, hitherto well, was suddenly seized with spasm of the platysma muscles whilst walking on the sands at Weston-super-Mare—the beginning of a serious breakdown. An editor, after 30 years' hard work, breaks down suddenly with labyrinthine vertigo at 55. Headaches, insomnia, depression, and irritability are often met with at an early stage. The symptoms present great variability, and the illness may begin with neuralgia, or neuritis (tic douloureux, sciatica, lumbago, torticollis).

---

[1] Presidential Address to the Hunterian Society.

CASE 1.—Father and one brother died in middle life of some lung affection. Mother and another brother had gout. Patient married, six children, climacteric at 49. At 51 a severe nervous breakdown—headaches, "spinal irritation," distressing pains relieved by many visits (sometimes twice in the year) to Buxton. She "cannot perspire too much," and in the winter is relieved by portable Turkish baths, massage, and frequent doses of calomel. At 60, referred to Strathpeffer. Neuritis in both lower limbs, preventing walking and sleep. Hepatic dyspepsia. A course of sulphur waters with alternate sulphur and peat baths and packs inducing free perspiration. This with great relief in two following years.

CASE 2.—Family history of longevity. At 55 recommended to Strathpeffer. A politician and lawyer and in Parliament, hard work for 30 years, now wakes every morning between 5 and 6 with a sense of strain in the head, pains in back and across the shoulders. Repeated long holidays combined with courses of baths. Lived to 80 in full work.

CASE 3.—Father died at 50. A business man, a careful liver with many years of hard and anxious work. Had sunstrokes in early life, 20 years in America, dyspepsia from hot food and ices. From 42 onwards occasional rheumatism and cramps. Lost six members of his family. At 50 a sudden nervous breakdown—acute pain in cervical and lumbar spine and limbs, attack of syncope lasting nearly two days, neuralgic pains "every few minutes." "Jenner said he could do nothing." Failure of digestion, 2 st. lost in weight, for three months confined to bed, passing much uric acid. Recommended by the late Sir William Gowers to Scotland for a long rest to the nerve centres. On arrival pain in upper limbs and shoulders on slight movements, head hot, vaso-motor disorder, urine and heart normal. Mild course of sulphur waters and sedative baths. Ascended Ben Wyvis before returning home.

CASE 4.—Headmaster of a large school, with responsible public and agricultural work in addition. Both parents died at 64. At 50 an attack of nervous depression and intense fatigue, unable to speak to his friends, pulse intermittent. At 54 a second breakdown, recommended to a health resort. Pain in right hypochondrium, liver contracted. Absolute rest, sedative baths, a full course of sulphur waters. At 57 reported to be quite free from symptoms.

Such cases occur to every practitioner. Those that I have quoted agree in having a somewhat sudden onset, a rather serious type of nervous disturbance, and generally prolonged and continuous mental strain. They also showed digestive, eliminative, and circulatory disorder, and a tendency to recurrence, making it necessary to avoid undue strain and to have recourse from time to time to sedative and eliminative treatment.

2. *Cardio-Vascular Changes and High Blood Pressure.*

In a medical report on the risks of middle life, presented to the Australasian Parliament in 1916, it is stated as a general belief that at about 40 years of age slow degenerative changes commonly begin in the large arteries, with an elevation of arterial blood pressure which may amount to about 30 per cent.; that the causes of such degeneration are threefold: (1) overstrain or fatigue, reflected in the nerve centres; (2) alimentary or catabolic toxæmia, usually from excess of food; (3) infection from the bowel or throat; adding that the kidneys may become the dominant cause of the toxæmia when the renal vessels are seriously affected. The report further points out the serious injury from nerve strain at from 40 to 50 years of age, the heavily increasing incidence of apoplexy after 40, and finally recommends that "provision be made to encourage the early diagnosis and treatment of high arterial tension," and incidentally, from this point of view, the oversight of the health of industrial workers. My own experience suggests that high arterial tension is mainly due to (1) overstrain connected with the conditions of modern life, and (2) inherited tendency.

CASE 5.—A King's counsel, with continuous brain work and of sedentary life. At 45 rheumatic gout in feet and knees, but "kept it under at Harrogate"; acid dyspepsia and (nota bene) bleeding piles. At 60 referred to the Scottish spa for eczema by the late Dr. James Little, of Dublin. Did well. At 64 a "stroke," but continued in full work for two years longer. Kept up his shooting and fishing in Sutherland until he was 73. Died at 75 of gradual failure. In this case the repeated courses of purgative water and the relief of excessive arterial tension by hæmorrhages from the bowels probably lengthened life by many years.

CASE 6.—Family history of death in middle life from paralysis, heart and kidney disease. Rather a free liver: gouty; eczema. At 55 Prof. Grainger Stewart observed albuminuria. From 57 to 61 frequent epistaxis (again nota bene). At 61 referred to Strathpeffer. A pale, stout man; urine generally with a trace of albumin. At 68 severe angina pectoris. At 69 died of bronchitis and heart failure. Here also I suggest that we may attribute to the loss of blood by epistaxis and to the spa treatment that this patient lived much longer than was usual in his family.

CASE 7.—An energetic Scotswoman, much abroad in responsible positions. At 45 her troubles began with "rheumatism" in the knees; at 48 the climacteric; recommended to Scotland; complains of blood to the head and vertigo, and asks to be bled. At 54 a second visit, circulation very uncomfortable, "sinking feelings at night." Second sound of heart very hard. At 58, systolic blood pressure 156, chilly extremities. I was anxious to ascertain the condition of the small vessels, and the late Mr. Marcus Gunn kindly reported "retinal arteries small and evidently sclerosed, veins a little compressed by them." This was a case of typical hyperpiesis as described by Sir Clifford Allbutt, with increasing arterial hypertonus or spasm. It was systematically treated by venesection, beginning at 58 with two venesections at a month's interval, followed by a course of tepid effervescent baths. At 59 a fourth course of waters, and a large natural hæmorrhage from rectum. At 60 much vertigo, heart's apex well outside nipple, right hemiparesis, confusion of speech for 24 hours. At 62 some vertigo; venesection 20 oz. Return of symptoms in three months, another venesection to 24 oz. Further venesections at 63 and 66. At 68 reported very well, leading a quiet life, 20 years after her first symptom of arterial hypertension. The relief experienced after blood-letting was immediate.

Many times in other cases I have seen apoplexy averted by a timely venesection. When the hypertension is causing much discomfort, a venesection may well be given before commencing a course of waters.

3. *Gout.*

It seems that in some gouty families the disturbances of middle life fall more upon the mucous membranes than upon the vascular system. The men, and women too, complain of "liver," heartburn, abdominal disturbance, headaches, giddiness, vague pains, many catarrhal symptoms, and circulatory disturbance. The pulse is generally weak and slow, but the tension is seldom high. After some years health is usually much better, and these people go on to a long age.

CASE 8.—A medical man with inheritance of gout on both sides. Many febrile "rheumatic" attacks in early life, with heartburn, flatus, and diarrhœa. After 22, very liable to aphonia and cough, and recurring lumbago. At 40, a severe digestive illness. At 43, referred to Strathpeffer for "rheumatism"; much too stout, heart normal, but action weak, urine normal, skin active. He was feeble and depressed, very liable to chill and sleeping badly. A full course of sulphur waters with douches and peat baths. Very well for two years. At 45, a second course of treatment for lumbago and malaise. Digestion fairly good. Heart, a suspicion of mitral systolic murmur: again much better. Six years later, aged 51, after prolonged hard work, a third course with similar good results.

4. *Glycosuria.*

The two following cases illustrate different types of glycosuria met with in the middle period of life:—

CASE 9.—A Scottish "merchant" or shopkeeper, sedentary; too much brandy; severe quinsy and enteric fever as a young man. At 53, severe pains in legs after repeated influenza, much lassitude, increasing pain, discovery of sugar in the urine. At 54, referred to Strathpeffer. Urine 40 oz., specific gravity 1035; sugar 9·4 gr. per oz. (one specimen 25 gr. per oz.); pulse 96, perspiring, tongue milky white. Sulphur waters, douches, and diet. Sugar rapidly reduced and absent after two weeks. The following year a second visit, reported much better. Had been very well all winter, but in the spring return of influenza with weakness and pains. Urine 42 oz., sugar 4·7 gr. per oz.; 40 oz. sulphur waters daily, with opium pills; increased diet. Volume of urine increased to 68 oz., sugar 1·9 gr. per oz., and large crystals of uric acid. At 56, a third course of waters. Has carried on very well, but knocks up in spring. Some pains in left arm and over heart, no murmur. Pulse 100. Liver enlarged. Urine not excessive, sugar 3½ gr. per oz.; again left the spa much better. Subsequently resumed and increased his brandy; attacks of tachycardia. Died at 59 of diabetic coma, after septic gum-boil.

CASE 10.—Family history, several short-lived members. An advocate. At 33, rheumatic fever; at 35, nervous breakdown from hard work and overstrain. Better after a sea-voyage. At 55, much run down. Sciatica, relieved at Wiesbaden. At 56, nervous depression, worried. Heart, very feeble action, often "fluttering" sensation behind sternum, no dilatation. Pulse 66, very soft. Systolic blood pressure 120–130; feels the cold, "expands in warm weather," drinks wine: occasional eczema and cramp of anal sphincter. Urine contains 0·5 per cent. of sugar. Diagnosis, "gouty, wear and tear, nervous and mental depression." Under dieting and cardiac tonics improved, the sugar continuing and the blood pressure remaining low. Took a course of waters and effervescing baths at Royat, and later, for poor circulation, sitz-baths at 115° F. for ten minutes every second night. At 57, after a year of unbroken work in the courts, referred to Vichy for water and baths. The blood pressure improved at Vichy to 140 systolic with increased vigour, sugar still present. The following year drank Mattoni or Evian water at home, with benefit. At 60, after a fatiguing session, systolic blood pressure registered only 100; referred to Harrogate and took a course of effervescing baths. This was repeated for several years, always improving his health and spirits, and invigorating the heart. An ammonia bath every night before dinner was also useful. During these years carried through much additional work—with periods of exhaustion, sense of impending disaster, sinking feelings or vertigo, apparently due to feebleness of the heart muscle. At 66, seemed well, but six months later jaundice supervened. Upon operation, the head of the pancreas was found to be enlarged and extremely hard, and the related lymphatic glands swollen; survived for six weeks. The glycosuria, which had been generally present for at least 11 years, disappeared when the jaundice set in.

5. *Lowered Resistance.*

There are some other illnesses of middle life, very various in form, which all seem to depend upon a rather sudden lowering of normal resistance. Most practitioners have seen the nervous and mental disturbance which in certain subjects follows surgical operations and shock. The common occurrence of Graves's disease and septic arthritis in women about the climacteric may be cited. A breakdown of resistance and a rapid invasion not uncommonly follows a prolonged local septic infection. An analogous breakdown sometimes unfortunately occurs in those who have been too much exposed to X rays. A simple case may serve to illustrate this series.

CASE 11.—Father died of renal disease at 66 and mother of paralysis at 60; father's sister died of goitre. A strong and active man; 11 years' hard work in the tropics, exchanged for an equally arduous life in England at 44. At 50, inflamed throat, fever, blood poisoning, hæmaturia, blotchy erythema. "Pure cultures of streptococci in throat and urine." After partial recovery from the acute condition, took a long rest abroad, but returned still feverish at night and wasting. Recommended by Dr. William Gordon, of Exeter, and Sir T. Barlow to the Scottish spa. Symmetrical enlargement of thyroid gland; rapid heart (120 recumbent), but no murmur. Nervous and muscular asthenia, skin moist, flushed, and remarkably hot. After a short course of cool effervescent baths, without much apparent benefit, spent a month on the northern coast followed by six weeks in an open tent on a high moor. Steady recovery; returned to "three-quarter work" in eight months, and went on with no further breakdown for 15 years. At 63, occasional slight febrile attacks. At 66, several acute attacks, with rigor and high fever, purging, and rapid wasting. Hands white and cold, nails blue; heart dilated, pulse 90, B.P. 48–125. Urine normal. Died of heart failure after a month's illness.

Features in Common.

A little reflection suggests that whatever their clinical form or the label that we attach to them, all these cases have two outstanding features in common: (1) A serious *nervous disturbance*, with its outward and visible signs of chronic fatigue, exhaustion, or shock. (2) Combined with this nervous disturbance, and probably related to it, a state of toxæmia from *lowered resistance* to autogenous or exogenous invasion. The nervous disturbance evidently affects the autonomic and sympathetic systems, and may take one of two forms—either vascular spasm (hypertonus), as in most cases of gout, hyperpiesis, angina pectoris and apoplexy, or else the contrary condition of vascular relaxation, as in Graves's disease, tachycardia, glycosuria, &c. There appears to me to be at first no clear dividing line between these different forms of incipient disease. They are rather different aspects of the same thing. The failure of health in middle life is often at first vague and indeterminate, not localised in particular organs, and therefore unfortunately easily overlooked. Later, its apparent localisation in one system or organ is apt to mask a widespread breakdown. Our use of labels ought not to obscure the fact that both mind and body have a share in this condition, and that on the physical side the nervous, vascular, glandular, digestive and eliminative functions are more or less disturbed. When the disease is definitely localised, treatment may prove no longer effectual.

Let me add that although they occur in middle age, when people begin to talk about Anno Domini, and when, as the Australian Committee remind us, some vascular changes are generally recognised, they do not appear to me to bear any of the characters of normal involution or senescence. They are, on the contrary, violent breaks in the continuity or equilibrium of health—storms which under favourable circumstances are often followed by many years of good weather. I must leave to others who are more competent the task of tracing the links of causation underlying such conditions. The present analysis is very tentative and incomplete. But we may ask, does it, so far as it goes, throw any light on the treatment of these disorders?

Some Conclusions.

(1) That periodical *cessation of work* and *change of scene* are not only the best preventives of breakdown, but also curative in slight cases. This will be readily admitted. One of the most gifted and public-spirited men in a great city, still leading a laborious life at 63, told me that since his severe illness at 44 he had "struggled on, by means of many holidays." Corruption, we are told, comes when even the best of customs becomes too customary. I would plead for a more scientific study of holidays. Many are worse than useless. Moreover, there is a point at which a man ceases to react pleasurably to new conditions, and when definite treatment is required.

(2) That at all stages treatment ought to be chiefly directed to (*a*) allaying the nervous disturbance, (*b*) removing the toxæmia.

(3) That the medical value of *climatic stations*, both in allaying nervous disturbance and in stimulating the healthy resistance of the tissues, is insufficiently recognised. In early breakdowns a prolonged "change of air" under judicious medical care often brings about a complete and permanent recovery. There are in Great Britain about 150 places which claim to be health resorts, and perhaps we forget both the variety and the efficacy of climatic treatment which lies at our doors.

(4) That *a properly appointed spa* unites the benefits of a holiday and of an appropriate climate, with the special effects of external treatments by baths and other applications, and also of internal treatment by some kind of medicinal waters, together with a powerful mental suggestion of health. What is called "spa treatment" is therefore obviously a complex prescription, and in serious cases needs much knowledge and discrimination.

(5) That *almost all cases of breakdown are curable* at an early stage, and that the experience of many good observers at spas and climatic stations shows encouraging results of treatment, even in what appear to be serious and even hopeless cases. It may be added that one of the most useful functions of the health resort is to prolong the active life of the brain worker.

(6) May I here interpolate from my own experience some suggestions for those who are engaged in treating the disorders of middle life by means of waters and baths?

(*a*) Increased elimination, as already stated, comes first. Saline waters are rightly esteemed, but of equal or even greater importance for the relief of chronic toxæmias are, in my opinion, the *diuretic waters* which produce a greater output from the kidneys than the intake of water. When combined with sedative or derivative baths, such waters are certainly beneficial in many cases of arterial hypertension. It is interesting from this point of view to remember that some endocrine secretions are believed to be powerfully diuretic.

(*b*) The *sedative treatment* of nervous disturbance comes next, and ought to be axiomatic in dealing with the results of overstrain. Apart from sedative climates, a long range of external applications is available. Winternitz was justified in his belief that by means of baths, still or effervescent, and graduated in point of time and temperature, it is possible to bring to bear in neuro-vascular disturbance almost any desired degree of sedative action.

(*c*) *Stimulating forms of external treatment* (cold salt frictions, contrast douches, &c.) increase the resistance of the tissues and fortify the body against microbial infections.

(*d*) *Blood formation can be stimulated* by the same means, especially in pure air and at a certain elevation. Moreover, if certain waters are at the same time taken internally, still better results in the restoration of the blood are obtained. Spa treatment of this type has therefore been recommended, I think justly, for anæmia, and is worthy of trial also for the changes induced by exposure to X rays.

(*e*) The remedies of the health resort are, of course, not admissible in the acute phases of disease. But let us not forget in these days of specialism the unity of medical practice. He who studies and practises the methods of the health resort is perhaps after all a specialist of another kind, for he devotes himself to the investigation of incipient and chronic maladies and to the application of physical remedies (in the words of Hippocrates, "airs and waters and places") to their relief.

(7) Lastly, though first in importance, I would submit that the systematic periodical *measurement of the health of middle-aged persons*, especially those engaged in mental labours and responsibilities, is greatly needed, especially now after the long strain of the war, and would be the means of averting many critical illnesses and prolonging many lives.

A Note on Measurements.—(1) The rapid development of vascular hypertension and hyperpiesis and the frequent occurrence of cerebral hæmorrhage in comparatively young men are, I believe, generally preventable. For this purpose careful records of pressure readings might well be kept during the danger period, especially in families showing a tendency to such accidents. (2) Is it possible in the same way to measure immunity or resistance? It is a familiar experience that in health the application of cold to the skin after an initial contraction of the vessels brings an increase of blood to the part, with vascular dilatation and a pleasant glow. I suggest that sluggishness or absence of this normal neuro-vascular reaction to cold is one clear sign of lowered resistance in the tissues. (3) The measurement of nervous sensibility and reflexes affords some criterion of nervous stability. Auditory hyperæsthesia is often a sign of overstrain, and any local ailment long in abeyance may be suddenly exaggerated. (4) On the mental side, the measurement of attention, concentration, memory, &c., may reveal the beginnings of serious disturbances.

All must agree that under an ideal dispensation of preventive and curative medicine these breakdowns in the mid-career of life would not take place. Ought they to be so common now? We cannot measure the tragic losses that they entail—the support of families, the slowly ripened fruit of experience, the gathered knowledge, applied in the very prime of life to the advancement of science and in the public service. I would ask you, cannot we do more to detect the danger and avert the blow?

"ANGELS ON THE WINDOW-SILL."

THE author of "The Corner of Harley Street" has written and illustrated a wholesome and delightful book of fairy stories for the modern child. "Half-past Bedtime" (by H. H. Bashford. London: George G. Harrap and Co., Ltd. 5*s*.) contains 14 chapters, each with a thrilling story that keeps the child spell-bound for 20 minutes and leaves him with something to ponder and wonder about. Town and country life, sea travel, winter sport, the garden of Eden, fairy land are all well-known to the author and are introduced to the child with quaint detail and little touches of medicine and psychology which are never allowed to obtrude unduly. Gwendolen's exceptionally large tummy, ascribed to sitting about eating marzipan, cured by a long voyage undertaken to return a monkey to his Southern island home. The dead son, longed for so ardently by the lonely judge, that he became visualised at play to the onlooking children. The blind painter whose blighted life was rendered happy again by the development of an acute sense of hearing which he was able to transmit to others. These are three examples of many. Dr. Bashford gently scoffs at the blindness of men in cities:

"Long ago they lost their eyes
Under bags of merchandise;"

and his stories will help to keep alive and direct into healthy channels the childish imagination which knows that

". . . . there are still
Angels on the window-sill."

PUBLIC HEALTH IN SWAZILAND.

ACCORDING to the Census taken last year the European population of Swaziland consisted of 1239 males and 966 females—total 2205, representing an increase of 103·6 per cent. since 1911. The native Bantu population numbered 52,761 males and 57,534 females—total 110,295, being an increase of 5·34 per cent. as compared with the previous Census. Coloured and other races other than Bantu also showed an increase. The general health of the territory in 1921 was fairly good. Amongst the natives small-pox, in epidemic form, broke out; but, with systematic vaccination, the disease did not spread to an alarming extent and there were few deaths; the Europeans were not affected. Malarial fever was milder than usual, due largely to the natives realising more and more the value of quinine, which is distributed amongst them. Scabies and syphilis continue to be prevalent amongst the native population, chiefly on account of the conditions of life in their kraals. The arrest of syphilis is somewhat hampered by the high cost of the latest forms of treatment, but with the coöperation of the police in notifying cases, everything is done that is possible. At the only hospital in the country (at Mbabane), where a gift of £500 from the Red Cross Society enabled the erection of a new building and three wards for Europeans, 177 cases were admitted. There were two deaths; 4209 out-patients were treated. The climate of the high veld has been likened to that of the south of France. The air is bracing and invigorating; light frosts are prevalent during the months of June and July; the mean temperature in winter is 57° F.; the summer is pleasantly warm. The average annual rainfall recorded at Mbabane over 18 years has been 53·04 inches. The middle veld is well watered by streams rising in the ranges on the west. Lying as it does some 2000 feet below the mountains, the summer temperature of this area is warm and humid, but in winter is cool and refreshing. The high veld is free from malaria, which is, however, prevalent in the low veld and in a slight degree in the middle veld during the summer months, but it is not of a virulent type and is easily avoided by taking the precautions ordinarily considered necessary in any subtropical country.

CALCULATING PRODIGIES.

To the Editor of THE LANCET.

SIR,—In your columns the reviewer of my pamphlet on "Calculating Prodigies"[1] has well brought out the point on which I wanted to attract general attention—namely, that the whole question is much more related to psychology than to pure mathematics. With regard to cases of mentally deficient children endowed with certain powers of calculation and mentioned in the letters of Drs. Bernard Hollander, G. A. Auden, and W. McAllister[2] as being instances unfavourable to the theory that early environment is mainly the cause of the powers of calculating prodigies and also instances seeming to suggest a relation between weakness of intellect and capacity for arithmetic, I should offer the four following considerations:—

1. Since Dr. Bernard Hollander is of opinion that there must be an anatomically distinct brain centre for arithmetical capacity, he should not wonder when a child, *in spite* (and not because) of his weak intellect, has that special centre *unimpaired* or well developed, whilst the other centres are altered or neutralised by physical malformation or disease.

2. By constantly using the word "environment" scientists have a tendency to consider environment as a well-defined entity, when, in truth, what is meant is the thousand and one details, circumstances, incidents, and accidents comprised in even the simplest round of daily life in any given place. Environment, in so narrow a field as an institution or asylum, has all the same this complex character, and some of the details and circumstances (extremely difficult to disentangle one from another) are likely to make an impression, and a strong one, on an inmate. The very fact, for a child, of being shut out from the big world, either by blindness (as in the quoted case of Fleury) or by disease, may bring into play tremendous psychological forces, which act so much the more powerfully that the child is younger.

3. Pathological cases, no doubt, give valuable indications to the psychologist and must not be neglected; but so it is with healthy cases, and medical men are, at times, apt to forget these.

4. Psychologists state that cases of arithmetical prodigies are strictly confined to boys or men. In my pamphlet, which mentions three of such calculators now living, I have drawn attention to the fact that one of them *is a lady*—a unique case, most probably, but one indicating that not too much stress should be laid on the so-called character of sex-limitation.

The mention of two native Fijian boy mental calculators by Dr. B. Glanvill Corney in THE LANCET of Dec. 16th is, to me, an extremely interesting case and *not* one against my views on the effect of early environment. For these boys, European influence has practically been non-existent, and apparently Fiji does not seem to be a field for mathematical cultivation. But J. J. Rousseau became famous by boldly stating that civilisation had taken man away from the influence of nature and had resulted in many harmful consequences for his heart and brain; in other words, that the natural state was much more conducive to happiness and sound knowledge than the artificiality of the civilised state. His paradox is full of truth, perhaps still more so to-day than in his time. The simple minds of poor shepherds leading their simple life in our old countries, or the unsophisticated minds of Fijian boys must be nearer natural (and perhaps scientific) truth than the European mind, moulded by school and tradition, constantly developing science and art, it is true, but always doing this *in the same direction*, that shown by the roads already laid down. Is it not noticeable as, in science and art, new paths were discovered by "outsiders"—that is to say, by men free from the prejudices of the professional? Was not Pasteur an *outsider* in relation to the medical world?

We generally take it for granted that *historical* evolution conforms to *logical* evolution and are too ready to conclude that the present state of any science is the outcome of logical evolution, whereas many factors (amongst which the wars and revolutions in history) have prevented or delayed logical evolution from reaching its ultimate goal. This is precisely what happened in arithmetic, when the *Arabic* conception suddenly and *accidentally* replaced the Greco-Roman tradition, that had not yet completed its final logical evolution. The calculating prodigies, by their peculiar early environment, are the few and exceptional beings who have escaped the influence of the Arabic conception, prevalent in modern science and modern teaching, and have again advanced in the direction of logical evolution.

In any case, the chief aim of my pamphlet is to urge scientific societies to conduct a methodical and exhaustive series of researches by submitting to numerous and proper psychological tests the calculating prodigies now living. These are so very few—and not at all mentally deficient!—that it would be a thousand pities not to seize the opportunity to make a thorough study of them. Of course, mathematicians should also do the same, independently from or together with psychologists.

I am, Sir, yours faithfully,
Dean-street, London, W., Dec. 23rd, 1922. V. NUMAIR.

[2] THE LANCET, Nov. 25th, et seq.

The Library Association.—The hon. secretary of the Association is now to be addressed at the Westminster Public Libraries, Buckingham Palace-road, London, S.W. 1.

B. C. F. L.—The suggestion that the criticism represents the views of someone in South Africa is unconvincing, for the article in question did not appear until Dec. 16th, 1922. The unsigned review is recognised as the best way of obtaining just appreciations, and the editor is responsible for its terms, as well as for the choice of reviewer. If we grant that in a text-book "the practical essentials are all that are necessary for a student and practitioner"—and no such admission is made—we cannot agree that "shortcomings are always pardonable." A book of instruction must not err in "practical essentials."

An Inquiry

INTO

PYLORIC STENOSIS OF INFANTS.

By LEONARD G. PARSONS, M.D., M.R.C.P. Lond.,

HON. PHYSICIAN, BIRMINGHAM AND MIDLAND HOSPITAL FOR SICK CHILDREN; PHYSICIAN, INFANTS HOSPITAL; AND ASSISTANT PHYSICIAN, GENERAL HOSPITAL, BIRMINGHAM;

AND

SEYMOUR G. BARLING, C.M.G., M.S. Lond., F.R.C.S. Eng.,

HON. SURGEON, BIRMINGHAM AND MIDLAND HOSPITAL FOR SICK CHILDREN, AND GENERAL HOSPITAL, BIRMINGHAM.

Introduction.

The objects of this paper are to examine critically the results of treatment of this condition in the authors' series of cases, and to give some results of attempts, still in progress, to investigate the nature of the disease and some of its symptoms. The statistics quoted will be from the authors' own cases and also from cases at the Birmingham and Midland Free Hospital for Sick Children.

There is no need to give the history of the discovery of this disease, but we would point out that although Hirschsprung, in 1888, first emphasised its clinical importance, it is to John Thomson and Still that the wide recognition of the disease is due. The surgical treatment in this country owes much to the work of Stiles, Burghard, Nicol, Dent, and recently to Tyrrell Gray, whose theory of "hyper-adrenalism" we criticise later on in this paper.

The symptoms are too well known to need discussion in detail; they can be concisely summed up as follows: Persistent and projectile vomiting, obstinate constipation, pronounced and progressive wasting in a nursling born healthy. We regard typical gastric peristalsis as characteristic of the disease, if it be accompanied by vomiting. A history only of vomiting is not always sufficient, even when peristalsis is present, for we have convinced ourselves that a very obvious and marked peristalsis of the characteristic slow type—i.e., three to four waves per minute—may occur without pyloric stenosis. One such case was admitted to hospital with a history of vomiting. On its admission vomiting did not occur, but there was very definite peristalsis of this type, and we, therefore, decided to operate upon it. An abdominal incision was made and when the pylorus was delivered it was seen to be normal and was returned to the abdomen; the abdomen was stitched up and the child made an uneventful recovery. Previous to this case we should have regarded peristalsis of this type as quite diagnostic of the disease. In spite of this error in diagnosis, we do not regard palpation of the pyloric tumour as essential. It can usually be felt, but the examination is often painful. As pointed out by Miller, palpation is usually only possible during the time of obvious peristalsis, because the stomach in diastole falls over and obscures the pylorus.

Radiographic Investigation.

Radiographic examination may be very useful as confirmatory evidence of a pyloric stenosis. We have had many of our cases radiographed, not primarily for the purpose of confirming the diagnosis, but to give some idea of the size of the stomach and as a means of investigation of the disease. The method used by Dr. C. G. Teall, the radiographer at the hospital, is to give a drachm of barium sulphate in a mixture of an ounce of milk and an ounce of water. The baby is spoon-fed, because it is found that there is thus less liability to vomit than if the mixture is given in the bottle. Cases have been radiographed before and after operation, and very striking differences have been observed. Variot [1] states that radiographic examination is the best single evidence of pyloric stenosis, and Strauss [2] also says that it is the most important means of making an actual exact diagnosis. The latter states it not only shows whether or no the case is one of pyloric stenosis, but decides for us immediately whether the patient is to receive medical or surgical treatment. We find we cannot agree with these dicta, because in the first place it is quite easy to make a diagnosis without an X ray examination, and in the second place X ray evidence of stasis, even of extreme stasis, is not certain evidence that pyloric stenosis exists. In a certain case which clinically was not a pyloric stenosis the X ray examination suggested that such stenosis was present, because in plates taken one or two hours after a meal nearly all the barium was retained in the stomach, very little having passed into the intestine. When this case came to autopsy the pylorus was found to be normal, thus agreeing with the other clinical signs. This appears to us conclusive evidence of the existence of pylorospasm, a fact which has been denied by many writers.

One of the advantages of Rammstedt's operation is that for a time it appears to eliminate a large part of the sphincter action of the pyloric musculature. For instance, in a case aged 11 weeks, before operation X ray examination showed very deep waves of peristalsis, all the food was in the stomach one hour after the meal, and after two hours two-thirds of the meal was in the stomach. Three weeks later, after Rammstedt's operation had been performed, X ray examination showed that at the end of 15 minutes half of the food had left the stomach, and at the end of 1 hour and 15 minutes the stomach was almost empty.

Five months later, when the child was aged 9 months, X ray examination showed that at the end of 15 minutes after the meal some food had left the stomach, and one hour after the meal half the food was present, and two hours after the meal the stomach was empty. It is true that in other wasting conditions of infancy, as will be shown later, emptying is very rapid, but in spite of that we think that the facts detailed are strong evidence for assuming that the sphincteric control is greatly diminished immediately after operation, and recovers some months later.

Chemical Investigations.

These are part of an investigation into the stomach contents of wasted babies by the fractional test-meal method. This investigation was undertaken to determine if it is possible by such means to define certain groups of cases amongst wasting babies, and to determine if Miller and Willcox's [3] conception of a pylorospasm due to hyperacidity was a correct one. It is hoped to publish the results of these investigations later. In the present communication only those referring to pyloric stenosis will be dealt with.

The test-meal is a 2 oz. meal, consisting of equal parts of milk and water. An interval of three hours is allowed between the last meal and the giving of the test-meal, and the stomach contents are withdrawn every half hour. We have not found it practicable in babies to remove the contents as frequently as at 15-minute intervals. The contents are removed by passing into the stomach a No. 6–7 Jacques soft rubber catheter, and withdrawing them by means of a record syringe. We should like, as a routine, to have had a longer interval between the giving of the test-meal and the previous meal, but as the cases investigated were those of wasting babies this was not thought advisable. Bile is rarely found in the withdrawn stomach contents in these subjects. We have never found it in pyloric stenosis, and its presence in the stomach contents or in the vomit we believe completely negatives the condition. The rate of emptying varies considerably in wasting babies. For instance, it may be impossible to obtain milk half an hour after feeding, but the average rate appears to be such that it is not possible to obtain milk from the stomach after a longer interval than two hours. In pyloric stenosis milk can still be withdrawn three hours after the test-feed; indeed, in one case milk was obtained five hours after a feed. The character of the resting juice is also interesting. In pyloric stenosis there is usually present milk-clot in considerable quantity, and there is a high rennin content, high total acidity, and high free acidity. Milk-clot, however, is rarely found in the stomach in cases which are not pyloric stenosis.

The method of examining the stomach contents has been as follows: The rennin has been estimated by the method described by Miller and Willcox,[3] and we have used both Topfer's method for estimation of free and combined acids and Volhard's method for the estimation of total chlorides. Except for what has been stated above we have so far not been able by Topfer's method to determine any curve of stomach secretion which could be regarded as typical of pyloric stenosis; Volhard's method has, however, shown (in the few cases in which it has been used) an absence of duodenal regurgitation when the curves were examined in the light of Bolton and Goodhart's[4] work.

HYPERADRENALISM IN THE MOTHER.

In a paper published recently Gray and Reynolds[5] elaborated Gray and Pirie's[6] theory that pyloric stenosis is due to hyperadrenalism in the mother, and they set forth this theory as an explanation of two things—viz., the hypertrophy of the pylorus and the diarrhœa which occurs in many cases after Rammstedt's operation. Their statement runs as follows:—

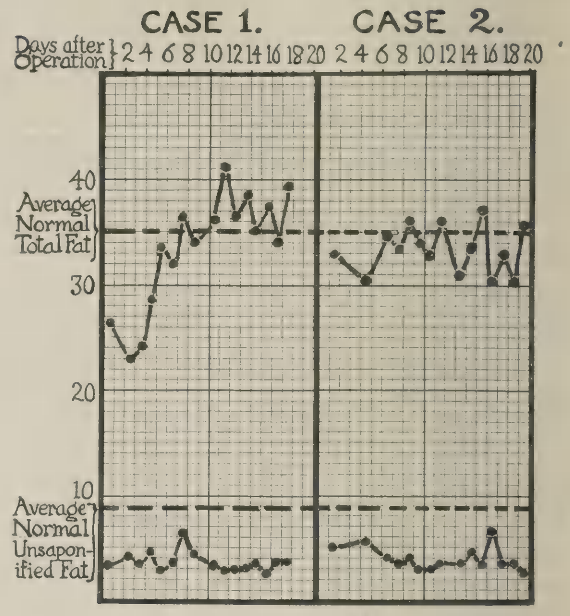
> "There is only one cause of localised hypertrophy of a muscle, and that is over-use. Clinical evidence appears to us to support the view that closure of the pyloric sphincter is controlled by stimulation of the sympathetic nerve-supply and by its hormone (adrenalin), and the logical inference is that the pyloric hypertrophy is associated with hyperadrenalism, the result of excessive sympathetic stimulation . . . Now there is no evidence of hyperadrenalism in the child, but since it is generally conceded that the hypertrophy takes place in utero, it is probable that the hyperadrenalism is maternal in origin. . . . Adrenalin being antagonistic to pancreatic function, it would be expected that pancreatic insufficiency (one manifestation of which is a failure to digest fats), would be a feature when obstruction is relieved. . . ."

They then go on to say that this failure in the digestion of fats is the cause of diarrhœa.

> "We feel the balance of evidence to be in favour of the view that both pyloric hypertrophy and pancreatic insufficiency are separate, but interacting manifestations of original hyperadrenalism, a view further supported by the fact that the size of the pylorus bears no relationship to the severity of the symptoms or the course of the disease. Thus the surgical breach of the vicious circle, by pyloric section, cures the obstruction immediately, but leaves untouched the pancreatic defect, which takes roughly as long to be re-established to the normal as the duration of the original symptoms. This has an important bearing on post-operative feeding."

Now the effect of adrenin on the pancreas is transient, and its results are hyperglycæmia and glycosuria. Assuming pancreatic insufficiency, the result of hyperadrenalism, did occur, it therefore follows that the hyperadrenalism must be a continuous condition and, therefore, must be present in the child, for hyperadrenalism in the mother could not produce this condition in the child after birth, and yet Gray and Reynolds state that there is no evidence of this in the child, and with this we quite agree. But, as a matter of fact, glycosuria does not occur and the blood-sugar figures are similar to those found by Guy[7] in other wasting infants—i.e., hyperglycæmia is not present, but there is a hypoglycæmia. In one case where vomiting was extremely severe the blood-sugar three hours after a meal was only 0·021 per cent., the highest figure we have obtained three hours after feeding being 0·069 per cent.

Further, if pancreatic insufficiency were present in these cases, and if that gave rise to diarrhœa as suggested, two results should follow. First, diarrhœa should be a frequent symptom in the history as detailed by the mother. This is not the case, and diarrhœa, when it occurs in cases treated by medical means, it is a late symptom in the disease. Secondly, in every case, after relief of the pyloric obstruction, whether diarrhœa be present or not, fat-splitting should be deficient, with the result that the percentage of unsplit fat in the stools should be high. To investigate this point we have analysed the stools of cases on which Rammstedt's operation has been done. The total fat and unsaponified fats in the dried fæces has been estimated in all stools passed for three weeks, commencing with the day of operation. For the purpose of this investigation the first stools can be regarded as what they are in reality—namely, the stools formed before operation. The accompanying graphs show two of the cases in which this investigation has been carried out, and it will be seen that the fat-splitting is normal; in fact the amount of unsplit fat is well below the normal line. It should be pointed out that the lower curve really gives a reading that is somewhat higher than the true unsplit fat reading because it includes free fatty acid.



Graphs from two cases of pyloric stenosis showing the percentages of total and unsaponified fat in dried fæces for three weeks following Rammstedt's operation. The normal in each case is shown by the dotted line and is calculated from Holt, Courtney, and Fales,[8] and from H. S. Hutchison.[9]

We would once more emphasise the point that if Gray and Pirie's theory be correct it must apply to every case; if it can be disproved in one or two cases it must be disregarded. These investigations show, we think conclusively, that the pancreatic function, as far as fat-splitting and carbohydrate metabolism is concerned, is normal and that the pancreas is not a factor in the production of diarrhœa, which may occur in cases treated either medically or surgically. We submit, therefore, that it is proved that there is no evidence of hyperadrenalism or of pancreatic insufficiency in the child.

Swale Vincent[10] has also criticised this theory from the standpoint of a physiologist, and it may be of interest briefly to recapitulate his points. He says that the evidence that adrenin constricts the pylorus is not convincing, and assuming that adrenin did act on the sympathetic, if there were hyperadrenalism its effects on the heart, blood-vessels, organic secretion, &c., would be so great that any increased constriction of the pylorus would not be noticed. He also says, in answer to a suggestion of Gray and Reynolds that emotionalism in the mother may be the cause of hyperadrenalism, that the emotional theory of adrenin secretion has never been firmly established, and asks the pertinent question, why is the mother herself unaffected by this hyperadrenalism?

CAUSATION OF DIARRHŒA.

The liability of these cases to diarrhœa is, however, a very important factor in treatment, and to ensure successful results it is essential to find out its cause. We believe that the diarrhœa may be due to one of two causes—viz., (1) faulty absorption, or (2) infective enteritis, a condition to which cases of pyloric stenosis, in common with other wasting conditions of infancy, are very prone. That absorption, not digestion, is at fault is, we think, obvious from the results quoted above—namely, that although fat may be in excess in the stools, it is present, not as undigested fat, but as split fat. Further, it is known that such stools are common in other wasting conditions, and, indeed, they may even occur without diarrhœa.

If faulty absorption be the essential factor, the condition of the small intestine is very important. If this is at all atrophic from disuse (which appears to be the case from post-mortem evidence) it cannot absorb any bulk of food, and, therefore, in treatment one should give frequent small feeds, leaving but little residue. We have found that diarrhœa is less frequent when such feeds are used in cases treated either medically or surgically. In cases where fat is present in the stools in excess, we give feeds having a low fat content—i.e., skim milk or a weak sweetened condensed milk mixture such as ½ dr. sweetened Nestlé's milk to 1 oz. of water.

Following on the results we have obtained we do not think it necessary to pancreatise the food before giving it to the child, and this is helpful in treatment because peptonisation of the milk imparts to it a taste which many infants dislike. The liability to infective enteritis is not greater in pyloric stenosis than in other cases of wasting from food disorders in infancy, and the methods of combating it are the same—e.g., scrupulous care in feeding, barrier system of nursing, limitation of number of such cases in a ward, avoidance of too long a stay in hospital, &c.

MEDICAL TREATMENT OF PYLORIC STENOSIS.

This was carried out in these cases on the usual lines, and on the principle that the chief exciting cause of the symptoms is pyloric spasm with blockage from swelling of the mucous membrane, although the underlying cause is the hypertrophy of the pylorus, which is of congenital origin. There are two great pitfalls to be avoided in medical treatment—first, the collapse that follows large vomits, by preventing such large vomits; and secondly, the getting of too large a quantity of food through the pylorus into the intestine which produces in many cases a fatal diarrhœa.

The indications for treatment are therefore three: (1) to relieve the gastritis; (2) to give food leaving a small residue—if this be done and the gastritis is relieved the result is the relief of the pyloric spasm; (3) to give frequent but small feeds.

The gastritis was relieved by washing out the stomach. Depending on the amount and frequency of the vomiting, the stomach was washed out once, twice, or three times in the 24 hours. If there was only one large vomit in the 24 hours the stomach was only washed out once; if more than one large vomit occurred the stomach was washed out twice or even three times, and the number of wash-outs diminished with the diminution in the vomiting. Wash-outs should not be left off too early, because of the liability to a large vomit which may be followed by a fatal collapse. After the first few wash-outs the child may be collapsed, but this should be guarded against by giving a dose of brandy after the wash-out. The wash-out should be given just before a milk feed is due; after the washing is clear the stomach tube may be used to introduce the feed. Wash-outs are given with an ordinary soft rubber catheter (No. 7 Jacques); a 1 per cent. sodium bicarbonate solution at 100° F. is used for this purpose.

Diet in Medical Treatment.

The diets given have been varied; if the child was fortunate enough to be breast-fed at the time of coming under observation—a rare occurrence—the milk has been withdrawn and 1 to 2 dr. have been given every hour. The breast milk is withdrawn because the effort of sucking may cause vomiting, and it is said also that it causes more pyloric spasm. Artificially-fed babies, who do not tolerate milk well, have been started on whey, veal broth, or a combination of raw beef juice and whey with or without cream (we should not now use cream) or even albumin water or plain water. If these were used, milk feeds have been started as soon as possible and the amount of food slowly increased. Our preference has been for citrated milk, starting with 1 to 2 dr. hourly; occasionally peptonised milk has appeared to suit better. Dried milks like Glaxo have also been used in a few cases. Beginning in this way, the diet was slowly increased and the intervals between the feeds lengthened. If vomiting became marked the amount was diminished, and when diarrhœa occurred weaker mixtures and smaller feeds were given. In addition to this treatment we have tried nasal feeding to diminish the frequency of the vomiting. This was suggested and practised successfully in one case by the late Dr. F. E. Batten. Subcutaneous and rectal salines have been given, and inunctions of cod-liver oil have occasionally been tried. As in all cases in wasting infants the necessity for warmth has been insisted upon.

Results of Medical Treatment.

The results of this treatment rigidly carried out have been in our hands very disappointing. The actual figures are 36 cases with 5 cures, which gives a recovery rate of 13·8 per cent. We must admit that these figures contrast very strikingly with those of John Thomson,[11] who gives a recovery rate of 42·5 per cent. in 61 cases treated by medical means. He states that his hospital statistics have been considerably worse than his private cases. We have seen very few cases in private, but not one has recovered on medical treatment only. On the other hand, Warren[12] gives 30 cases in the East London Hospital, treated medically, and all died but one, and that, he states, was a doubtful case. Gray and Pirie give Great Ormond-street statistics for 1915–16–17, and out of 54 cases, the mortality was 80·5 per cent., this included a certain number of cases operated upon, the latter giving a death-rate of 100 per cent.

Treatment, even in the cases that recovered, was a very long process, lasting three to four and even six months. The course of recovery was marked by a succession of ups and downs, a long period of time in which no increase in weight occurred, or in which the gains were very slight and frequently did not neutralise the losses. At any time during the treatment a fatal attack of diarrhœa or fatal collapse after a vomit might occur. In the fatal cases death occurred from: (1) asthenia, after progressive wasting or after a long period of more or less stationary weight; (2) sudden collapse following a large vomit, or occurring at times without vomiting; (3) diarrhœa, either an infective enteritis, or of the non-absorptive type. In any case treated by medical means, if the child can be kept alive until about six months old, improvement will occur, and after that age set-backs are rarely seen.

SURGICAL TREATMENT OF PYLORIC STENOSIS.

Owing to the war an opportunity was given to review the results of medical treatment whilst away from civil practice. During this period better methods of combating shock were evolved and the necessity for speed was realised more than previously. We were determined on returning to children's work that all cases of pyloric stenosis should be operated on, in order to see if better results could be obtained than by medical means, and also because to make operative procedure the routine in every case was the only way in which a real comparison could be made with medical treatment, and to give us an answer to the question—Does surgical or medical treatment offer the better chance of success?

Prior to this, surgical treatment was adopted in a few of our cases, but all of these had been unsuccessfully treated by medical means, and it was only after a varying period of such treatment and owing to its lack of success, that surgical treatment was undertaken. The operation in each case was gastro-enterostomy; in all, eight cases were operated upon with two recoveries. We decided to make this the operation of election. However, before we were able to put this determination into practice, Gray and Pirie's[6] paper on Rammstedt's operation appeared and we were so impressed by it that we determined to make use of this operation. Until recently surgical treatment of these cases has not been generally resorted to. Procedures such as pyloroplasty, forcible dilatation of the canal (Loreta), and gastro-enterostomy have been tried tentatively by surgeons, usually in cases that had done badly under medical treatment; altogether a fair number of cases have been operated on by one or other of these methods. Thus Fisk,[13] in a review of 71 cases which had been operated on by various surgeons up to the time of his paper, gives the following figures: 42 gastro-enterostomies, mortality 43 per cent.; 11 pyloroplasties, mortality 45 per cent.; 18 divulsions, mortality 50 per cent. Total 71 cases. Mortality all methods 46 per cent.

These figures probably represent the best results that are to be obtained by these methods. Gastro-enterostomy was the method of choice in the majority of cases, though the exposure of the abdominal contents involved, and the length of time taken by the operation, make it unsuitable for these patients, and it is not free from the occasional post-operative risks. An otherwise successful case, upon which Mikulicz performed gastro-enterostomy, died from peptic ulcer of the jejunum two months after operation. The introduction of Rammstedt's operation has given us a procedure at once simple and efficient to deal with the mechanical problem presented by the condition.

Examination of transverse and longitudinal sections of the pylorus shows that its mucous membrane is compressed by the thickened circular muscular coat, so that its lumen is stellate or U-shaped on transverse section, and longitudinal incision of the serous and muscular coats down to, but not through, the mucous layer allows prolapse of the imprisoned mucous membrane and restoration of the lumen of the canal. Such a procedure is easily and quickly carried out, involves little exposure of the abdominal contents, and, moreover, appears to have no deleterious effects on gastric or duodenal physiology, as the food passing by the natural channel over the duodenal mucous membrane supplies the normal stimulus to pancreatic secretion and permits effective neutralisation of the acid chyme—functions interfered with by a short-circuiting operation such as gastro-enterostomy. As the result of increasing experience with this operation we have gradually superseded purely medical treatment in the greater number of cases, and believe that the best results will ultimately be obtained, if relief of the stenosis is considered essentially a surgical problem. The dieting of cases after operation presents many difficulties to the physician, and careful preparation for operation and skilful and devoted nursing in the post-operative period are as essential as a carefully executed operation if success is to be achieved; the margin of safety being a very limited one in many of the cases.

Pre-Operative Treatment.

After the diagnosis is established two or three days should be allowed to elapse in order to get the patient in the best possible condition for operation. During this period weight may be gained to a small extent, though frequently it remains stationary or falls in spite of ideal conditions. Lavage of the stomach twice a day diminishes gastritis and lessens the swelling of the mucous membrane of the embarrassed pylorus, and prevents absorption of decomposition products. Feeding along lines previously indicated is carried out up to within four hours of operation. It should be supplemented, if possible, by the addition of glucose and water between feeds. In patients who are very wasted, subcutaneous saline may be given daily in small amount (5 oz.), and one hour before operation fluid should always be thus given into the axillæ. Five hours before operation a rectal wash-out is given, lavage of the stomach performed two hours before operation, whilst by mouth a drachm of glucose in 1½ oz. of water may be given one hour before operation. The patient's limbs should be bandaged in cotton-wool and atropine 1/400 gr. administered half an hour before operation.

Operation.

Every attempt must be made to diminish shock, by gentleness, conservation of heat, and speed. A theatre temperature of 75° F., and hot-water bottles in proximity to the patient are necessary, whilst careful planning of the details of the operation allow it to be carried out in an unhurried manner in from 7 to 9 minutes. A mixture, two parts of ether, one part of chloroform, has been used to anæsthetise the majority of our patients. Latterly the use of nitrous oxide and oxygen has been tried as suggested by Gray and Reynolds, and we now favour it as the anæsthetic of choice and hope to diminish the mortality by its further use. Great care must be taken to keep the infant well oxygenated throughout, whilst to assist relaxation at the appropriate moment the mixture may be bubbled through the ether-chloroform mixture mentioned for a few moments prior to suture of the abdominal wall.

The abdominal incision should be two inches long and commence half an inch below the right costal margin, at the junction of the lateral one-third with the medial two-thirds of the right rectus. When the peritoneum is opened the liver appears in the upper two-thirds of the wound, and on retracting the lower angle the dilated pyloric segment of the stomach is seen. This is gently drawn out and held by the assistant with a mop. Along the slightly tautened lesser curvature the operator's finger seeks the pylorus to the right of the spine. The fixation of the pylorus varies very much. At times it lies closely applied to the posterior abdominal wall; at others it can be readily drawn up to the wound. Traction on the pylorus should be avoided as far as possible, and in seeking to bring it into view when it is fixed, the operator must depress the margins of the wound down to its site. With the pylorus held firmly between forefinger and thumb of the left hand, its anterior surface is in full view and the longitudinal incision can be delicately made when resting the knife hand on the abdomen to the left of the wound. The incision is placed as near the upper border of the pylorus as possible. Its length is about three-quarters of an inch, but varies with the length of the thickened pylorus. Starting a third of the length of the pyloric segment from the duodenum, it deepens as it reaches the middle of the thickened portion and becomes shallow as the stomach is approached. When the centre of the wound reaches a depth of about 3 mm., the whitish mucous membrane comes into view and is easily distinguishable. It is our custom to complete the operation by a blunt dissection, and for preference we use the rounded end of a Watson Cheyne dissector. With this instrument the thickened muscle at the two ends of the wound is gently torn through, allowing the mucous membrane to prolapse till it is almost flush with the serous coat throughout the length of the wound. Towards the duodenal end the greatest care must be taken, as the muscular coat thins abruptly and the mucous coat here is thin and adherent and may easily be torn through in deepening the incision. At the proximal end of the incision the thickened pyloric muscle gradually shades into the musculature of the stomach and no difficulty is found in carrying the section in this direction. Prolapse of the mucous membrane is favoured by gently squeezing the pylorus with the finger and thumb and by undermining the mucous membrane on either side of the incision. Bleeding is usually very trifling, but at this stage the pylorus should be released and then watched for a few moments. Occasionally bleeding is free, generally at the gastric end of the incision; if touched with a mop moistened with hydrogen peroxide the oozing ceases and a fine catgut suture should underpin any point which is still bleeding. We lost one case in our series from such hæmorrhage before the danger was recognised.

The pylorus is now allowed to fall back into the abdomen and the wound sutured in three layers. In three cases we covered the wound of the pylorus by an omental graft, but this measure prolongs the operation and appears to offer no special advantage; post mortem, in cases where no graft is applied, the incision is found filled with organised lymph and flush with the serous coat. In addition to the variation in fixation of the pylorus which has been noted above, it will be found to vary in size and in vascularity, points which are of importance in carrying out the operation. The thickened muscular cylinder of the pylorus is characteristically hard in all cases, but varies in length from about three-eighths to three-quarters of an inch, in the short type the mass will feel almost spherical, whilst the long variety will be definitely cylindrical. The length of the incision through the serous and muscular coats must vary with the type. We are, however, unable to correlate any variation in symptoms in the two types. Typically the pylorus is white and avascular, but from time to time specimens are seen which are red and bleed freely on incision. Apart from this, occasionally a vessel is divided in the incision in the avascular type, which gives rise to troublesome bleeding.

POST-OPERATIVE MEASURES.

After operation the patient, on being placed in bed, is warmed up by being put beneath a cradle, from which two or three electric lights are suspended, and is given a small rectal saline containing 1 dr. glucose, before coming fully round from the anæsthetic. This is repeated four-hourly for 12 hours, and then six-hourly for 24 hours. If the rectal salines are retained they may be administered eight-hourly for another day. Two hours after the anæsthetic 10 minims of brandy in 1 oz. of water may be given by the mouth, and this is repeated two-hourly until at 12 hours after the operation the first feed of milk and water is given. This feed consists of half an ounce of milk and half an ounce of water, or if the child is breast-fed 4 to 6 dr. of breast-milk previously withdrawn, to which is added 4 to 6 dr. of water. This is given two-hourly for 24 hours, and during this period the dose of brandy is dropped to 5 minims, or may be stopped altogether. The milk is now increased slowly until 1 oz. of breast-milk or 6 dr. of milk and water are being taken two-hourly. In addition glucose and water is given if the child is thirsty.

After an interval of three days from the operation, feeds are made three-hourly ones, and the amount at a feed is continuously but cautiously increased by about a drachm at a time; at the end of a week after operation the child should be having about 1½ oz. of milk and 1½ oz. of water, or a 3 oz. breast-feed. We do not aim at getting a rapid increase in weight, but prefer a slow and steady rise; indeed, some of our cases which have recovered have shown very little increase in weight for the first fortnight. Originally we gave larger feeds, as advocated by Gray and Pirie. By this method considerable increases in weight occurred very soon after the operation, but the risk of diarrhœa appeared to be appreciably more than by the method we now adopt. Indeed, diarrhœa is largely eliminated by this method of giving small feeds. We keep the cases in hospital about four weeks, and they are usually sent home taking equal parts of milk and water, about 2 oz. of each, or 3 oz. of breast-feed.

RESULTS.

Fifty cases in all have been operated on, 42 males and 8 females. Of these 43 were hospital cases and 7 were private cases, two of the latter being children of medical men. Of the 50 cases, 26 were cured and 24 died, giving a recovery-rate of 52 per cent. All the private cases recovered.

It has been our rule during the period under review —1920, 1921, and part of 1922—to operate on all cases of the disease which have come under our care, and it will be seen from the weights of the cases that many of the hospital cases were extremely asthenic when they were first diagnosed. The average weight of the "cured" cases was 7 lb. 1 oz. at operation, whilst that of the "died" cases was 5 lb. 12½ oz., the lowest weight being 4 lb. 6 oz. One case (our first), which was 5 lb. 5½ oz. at operation, gained 10½ oz., and then died three weeks after operation of enteritis. With improved after-treatment it is believed that such a case might now be saved. This particular case was cyanosed and cold when first admitted to hospital, and improved greatly at first in the post-operative period.

In the fatal cases the survival period after operation was as follows: Under 24 hours, 9; 24 to 48 hours, 3; 48 hours to 1 week, 4; 1 to 2 weeks, 3; over 2 weeks, 5. Total 24.

The last five cases died between the fifteenth and thirty-fifth days after operation, enteritis being the cause of death in all cases but one, this case dying of pneumonia. The post-operative gain of weight was as follows in three of the above cases: 8 oz., 5 oz., and 10½ oz. and we attribute death in these cases chiefly to the too rapid increase in the post-operative diet, a danger which has been considered above in discussing after-treatment. Twelve cases died within 48 hours of operation. In one of these hæmorrhage at the site of incision was the cause of death, though one bleeding vessel had been underpinned at operation. Another case died of convulsions, which were present both before and after operation, and one patient, after doing well for 24 hours, developed hyperpyrexia (105°), and died the second day. A case dying at the end of 12 hours showed at post-mortem collapse of both lung bases with early left-sided broncho-pneumonia. In other cases death appeared to result from post-operative collapse without definite post-mortem findings. Two other cases which survived from two to three days died after rallying from severe post-operative collapse, and may reasonably be included amongst those dying of the effects of operation. In one case which lived four days, the duodenum was accidentally opened at operation, and in another case re-suture of the abdominal wound had to be performed on the eighth day and the patient afterwards died of broncho-pneumonia. One patient died suddenly on the eleventh day without assignable cause, after a quiet convalescence up to the time of death.

In judging the mortality of the operation as presented in this series of cases, due consideration must be given to the fact that all cases of the disease presenting themselves were operated on without selection. Representing, too, as they do the first cases operated on by a new method, improvement should follow familiarity with the operation, and improvement in technical details, and such operative accidents as hæmorrhage from the incision and opening the duodenum, should be eliminated by experience. Gas and oxygen as an anæsthetic appears eminently suitable and should reduce the high mortality resulting from post-operative collapse. Above all, we feel that only by early diagnosis and early operation can the mortality of the disease be radically lessened, and in this connexion we would point out the great difference in the average weight of the cases that recovered, compared with that of those that died; though for the most part babies who develop the condition are well nourished at birth. Also the difference in the recovery-rate of our private cases (100 per cent.) and hospital cases (44 per cent.) is significant.

In a series of 38 cases operated on by Gray and Reynolds the mortality is given as 55 per cent. They exclude, however, four fatal cases, because two of them died of an epidemic which was prevalent at the time, and two died from accidental causes early in their experience. If these four cases are included, as they should be if the series is to be contrasted with ours, it gives them a recovery rate of 41 per cent. Taking into consideration their figures and our own, we think that a fair estimate would be that in cases diagnosed early, whose weight was about 7½ lb., at least 80 per cent. could be cured by this operation.

POST-OPERATIVE PHENOMENA.

Occasional vomiting after operation is usual and may occur from time to time during the first fortnight in cases that are otherwise convalescing satisfactorily. The vomits, however, in frequency, in amount, and in character, in nowise resemble those seen in the cases before operation. We were at first inclined to regard them as due to an operative error—that in over-anxiety to avoid opening the duodenal mucosa we had left a ring of pyloric muscle untouched by the incision. We have seen no ill-result following from this cause, however, provided the mucosa on the stomach side of the pylorus and of the greater part of the canal is well freed. The vomiting is rather the result of an over-acting and hypertrophied stomach accompanied by gastritis, and a stomach wash-out will sometimes relieve this vomiting absolutely.

Post-operative pyrexia is common and in the cases that recovered varied from 100° to 102·4°. In three cases that died within 48 hours of operation, the temperature reached 104·8°, 105°, and 106°, and such hyperpyrexia appears to constitute a danger, although Gray and Reynolds quote a case with a temperature of 106° which recovered. In discussing this question they consider this hyperpyrexia to be almost wholly due to the anæsthetic, and that it is almost entirely eliminated by the use of gas and oxygen. We feel that the risk both of post-operative pyrexia and vomiting will be diminished by careful pre-operative preparation.

The dangers of post-operative diarrhœa have already been mentioned, but we would like once more to emphasise the point that we treat the diarrhœa when present by giving small and well-diluted feeds, and also we administer the mist. ol. ric. cum hydrarg. of the Great Ormond-street pharmacopœia. If soapy stools are present, then milk with a poor fat content—e.g., skim milk or Nestlé's condensed sweetened milk—is used as previously indicated.

Our earliest cures were operated on over two years ago and in all who survived, digestion, growth, and development have been satisfactory once the initial difficulties of the post-operative period have been passed, and the operation, relieving as it does the temporary obstruction of the pylorus, yet appears to inflict no permanent injury on the sphincter action of the pyloric muscle, which is shown by X ray examination to have recovered its function after some months.

SUMMARY.

1. The paper is based on an analysis of 94 cases of the disease, of which 36 were treated by medical means, 8 by gastro-enterostomy after failure of medical measures, and 50 by Rammstedt's operation.

2. The results of medical treatment alone are very unsatisfactory.

3. Relief of the obstruction by Rammstedt's operation preceded and followed by a careful medical regime offers the best means of reducing the high mortality of the disease.

4. Rammstedt's operation allows the redundant mucous membrane to bulge and for a time abolishes the sphincteric activity of the pylorus.

5. Given early diagnosis and resort to treatment as above, we believe the mortality can be reduced to 20 per cent.

6. Functional test-meal examination of the stomach shows high rennin, high free acidity, and high total acidity in the resting juice, delayed emptying and absence of duodenal regurgitation.

7. Chemical analysis of the stools negatives the suggestion that these patients are suffering from pancreatic insufficiency.

8. This and other evidence is opposed to the hyper-adrenalism theory of the cause of hypertrophy as put forward by Gray, Pirie, and Reynolds.

We wish to express our thanks to our colleagues at the Birmingham and Midland Free Hospital for Sick Children for allowing us to make use of their records, to Mr. L. C. Brookes, assistant in the bio-chemical department, for his kindness in carrying out the chemical analyses, and to Dr. Henry Featherstone, honorary anæsthetist to the hospital, for his skilled assistance in the performance of operations.

ADDISON'S ANÆMIA.

BY HASTINGS GILFORD, F.R.C.S. ENG.,
FORMERLY HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AMONG the many explanations for the origin and nature of Addison's, or pernicious, anæmia, one is so simple and yet so sufficient that I venture to bring it forward for the consideration of those who are interested in the subject.

According to this theory Addison's anæmia is no more than a premature degeneration or senescence of the red blood organs. At first sight nothing can seem wider of the mark than the suggestion that a disease characterised by the extreme youth and vigorous growth of cells should be a manifestation of a time of life we associate with sloth, atrophy, and decay. Evidently for such a theory to be entertained we must have a conception of the nature of the senile change different from that now usually held. Elsewhere[1] reasons have been given for regarding the degeneration of old age as a reversal, whereby the body as a whole, or its organs individually, roughly speaking retrace the steps of their development and resume their young state. In other words, not only is there a second childhood of the body as a whole, but each organ is liable to become less complex, to fall back into a state of simplicity reminiscent of the earlier stages of its development. In the case of some organs the occurrence of such a cycle is fairly obvious. Thus both the male and female reproductive organs, which begin their active life at adolescence, tend to resume their infantile forms in old age. Cell systems of the brain also lose their arborescent processes and return to a simpler form; and similar reversal may be witnessed in the jaw and other organs.

Senility and Pernicious Anæmia of the Aged.

But in normal conditions we know nothing of a blood state at 70, or even at 100, in any way comparable with that of the embryo or of the fœtus. There are at least two reasons for this. The first is that the blood, unlike the reproductive system, being one of the first of the tissues to develop, is therefore one of the last to decline. Its life cycle is indeed so long that in normal circumstances it is never completed. Other vital organs with shorter cycles begin and finish earlier, and so put an end to life before the blood has arrived at senescence. The second is that among the old a blood state which is either that of Addison's anæmia, or is on the verge of Addison's anæmia, is more common than is generally supposed. I have myself seen examples of this pernicious anæmia of old age only because I have been on the look-out for it for many years. I believe that in each case death would ordinarily have been certified as due to "senile decay." In the very old the symptoms of the anæmia so merge into those of senility that, failing a special blood examination, the blood disorder is not easily to be recognised. I regard this as strong evidence that Addison's anæmia is no more than an anticipated senescence of the erythrocyte organs. As might be expected of a diseased state due to premature senescence, the younger the patient, or, in other words, the earlier the degeneration, the more malignant the disease.

---

[1] Gilford, H.: Disorders of Postnatal Growth and Development, 1911.

Probably in order that there should be a degenerative overgrowth of the red marrow it is essential that it should occur prematurely. There must be not only degeneration of the one system of organs but comparative youth of the body in general.

Predisposing Factors.

For Addison's anæmia to arise one of two things is necessary. One is some strain on the red blood organs such as is calculated to break them down, to render them senile before their time. The other is an inherent disposition of these organs to become prematurely aged. And this poorness of stock, conducive to a short life, may be hereditary. As a matter of fact, properly to understand the abnormal state we are now considering we must regard it in its biological or genetic aspects rather than as a problem of pathology. For if it be a manifestation of premature senescence, Addison's anæmia is evidently in the first place a biological extreme, and only in the second place a disease. Now the biological term for such extremes of normal processes is "variation," and if Addison's anæmia be of such a nature we may expect it to occur in one, or both, of two forms. We should anticipate that there is a form in which a tendency or predisposition to early senility so coöperates with certain external or exciting agents as to produce the variation. We have no difficulty in recognising these two factors in the production of Addison's anæmia.

Among these external, active, environmental agents are any circumstances calculated to worry, or irritate, or poison the red marrow as an organ, causing it to live a short life, to break down prematurely. Among them we must above all include such poisons as act constantly and over long periods so as insidiously to overcome, less by the vigour of their attack than by its persistence. Chief among them are certain toxins poured out constantly into the intestinal tract, the toxins of syphilis, lead, and occasionally arsenic or X rays. Prolonged bleeding may also apparently so exhaust the vitality of the red marrow as to bring about its degeneration, especially if the body in general be debilitated by cancer, by age, or other cause. Probably in every case the passive, intrinsic, or predisposing factor is also present, acting with an intensity which varies from that of a slight predisposition at the one extreme to an irresistible bias at the other.

Addison's Anæmia a Variation.

This is tantamount to saying that Addison's anæmia is a variation. It is that form of variation which is the outcome of inborn tendencies acted upon by an environment congenial to degeneration. It is a fluctuation. Regarded in this light any evidence of heredity is of importance, for the more definitely such transmission occurs the more convinced are we that we have to do with a disorder which has its springs in something inherent to the body. Now it cannot be said that instances of the hereditary transmission of Addison's anæmia are common; indeed, if we may judge from the number recorded, they are decidedly rare. Yet so uncommon is the disease that every case has so much the more significance. Only a few weeks ago I was consulted by Dr. A. N. Hooper about a lady of 65 who had advanced Addison's anæmia, for which no cause could be found, and from which she afterwards died. I then heard that two of her first cousins had died from the same complaint, and that a sister had died in childhood from purpura hæmorrhagica.

Some 12 years ago I recorded[1] a still more definite example of this kind of heredity. In a family of ten brothers and sisters, one brother died at 26 and a sister at 20, both from Addison's anæmia. An uncle had also died from Addison's anæmia at 63, and his mother had died from "extreme nervous prostration" at 60, no other cause being known. In each case the nature of the anæmia had been verified by blood examination. Since then another brother has died at the age of 35 from the same complaint, and a post-mortem examination failed to reveal any cause for the anæmia. Nor could any cause be found among the other cases. G. L. Gulland[2] has "come across three cases in people in middle life whose fathers had died of pernicious anæmia, in one case 10, in another 12, and in the third eight years before." Gulland and Goodall[3] write that "it is quite common to get a history of one other case in the family, and in one instance a patient's father, paternal uncle, brother, and sister had all died of the disease." Still more recently a convincing instance of heredity has been recorded by A. J. Patek,[4] in which in the same family an uncle, his niece, two nephews, and one cousin died from Addison's anæmia. In one of these nephews the disease took the aplastic form and was associated with sclerosis of the spinal cord. Blood examinations were made in each case.

It is characteristic of biological variations that when heredity takes place the variation which is transmitted is apt to begin earlier and to occur in a more malignant form in each succeeding generation. Such "intensification" and "anticipation" may be observed in some of these instances of hereditary pernicious anæmias. But it is hardly to be supposed that a disease coming on intensively in a youth will be manifested in the same way as when it arises in an old man. Hence we must expect that Addison's anæmia will sometimes be much modified by its occurrence in the young. Now there is good reason to regard aplastic anæmia as such a modification, and it will have been noticed that one of Patek's cases was aplastic. Moreover, in my first example of heredity a niece died from "purpura hæmorrhagica," with symptoms highly suggestive of aplastic anæmia. A good deal of evidence has been gathered to show that hereditary weakness in an organ, such as leads to premature senescence, is manifested in the form of a delay or arrest of progressive development. In other words, what is a premature senescence in the father may appear as a defect of development when anticipated in the son. Hence it is suggestive that Addison's anæmia occurs with all degrees of severity according to the age of its onset. In the old it is a comparatively benign complaint. In the young it is much more severe and may assume a malignant and fulminating form in aplastic anæmia. In this disease there is every indication of an arrest of development or infantilism of the red blood organs culminating in premature degeneration or senilism.

In aplastic anæmia the halt in the development of the red marrow may be so obvious and the absence of an exciting cause so complete as to suggest that the disorder is a germinal variation or mutation rather than a fluctuation. But so far the evidence of heredity is not strong enough to enable us to be sure on this point.

Developmental Origin of the Disease.

The picture of Addison's anæmia which now presents itself is as follows. Owing to an inherent defect in the red-blood-forming organs of the body, assisted in varying degrees by a debilitating and ageing environment, these organs become prematurely worn out and senescent. Nothing is more conducive to such a shortened life than a shortened period of progressive development whereby the whole cycle first of progress and then of regress is curtailed. The red marrow passes through its second infancy to a phase of regressive development comparable with that of its fœtal condition in progressive development. Its cells now simulate those of the embryonic marrow, but apart from their primitive aspect there is no ground for assuming that they are really embryonic. There are notable differences between the marrow filled with genuinely young cells engaged in constructive work, such as may be observed in young life or after severe hæmorrhage, and the marrow of Addison's anæmia. So also is the destiny of the cells different. Those of the marrow engaged in the repair of blood tissue are not destroyed, but fulfil their proper task as members of the newly formed blood community. In Addison's anæmia, on the other hand, the swollen marrow behaves far more like a neoplasm than like a normal organ. Its tissue is in a state of insanity, for its cells multiply incoherently without method, and are poured into the blood-stream apparently for no purpose but that of destruction. They are not really embryonic, but are quasi-embryonic or embryonoid. Such retrograde cells, incapable of improvement, are to all intents foreigners. As Woods Hutchinson long ago pointed out, they are comparable with the blood discs of some lower animal, and therefore go the way of all alien cells when introduced into the blood. Some of the salient features of Addison's anæmia perpetuated in its various names are also indicative of a disease of developmental origin. Thus it is a "primary" or "essential" anæmia, for it is self-dependent and not a manifestation of some other morbid state. This is consistent with the view that it has its basis in a physiological process, rendered pathological by occurring before its time. For the same reason its causes are obscure. It is "cryptogenetic." Then, like all developmental processes, Addison's anæmia is "progressive." And as development is never in a straight line, but is always variable or rhythmic, so also is the course of this disorder uneven or wavy. And as there is but one ending to normal senescence, so also is every case of Addison's anæmia "pernicious," "malignant." and fatal.

[3] Gulland, G. L., and Goodall, Alex.: The Blood, p. 101.

[4] Patek, A. J.: Jour. Amer. Med. Assoc., 1911, lvi., 1315

If the view now advanced be correct, then the place which Addison's anæmia should hold among diseases is with the errors of development. We are too prone to assume that development can go wrong only in its opening phases, for there can be no shadow of doubt that its closing phases must also be open to mistakes. Moreover, as every organ is liable to such errors of omission and commission it is hardly possible that such an important organ as that which forms the red blood should be exempt. Failure of the red blood organs to develop we recognise in aplastic anæmia; too early senescence in pernicious or Addison's anæmia.

The above, then, is a rough sketch of the theory. It is believed that by its means every fact that is recorded about Addison's anæmia can be naturally and easily fitted into its place in relation to other facts. Furthermore, there are other diseases closely allied to Addison's anæmia which can readily be explained in a similar way. For instance, if one makes allowance for differences in structure and function, the same explanation will apply equally to leukæmia as to Addison's anæmia. In leukæmia there is also an enormous over-production of cells—though in this case it is of leucocytes, not of chromocytes—and the same blight of degeneration which produces such a copious supply of inferior, embryonoid, cells interferes with the mechanism which would ordinarily ensure their destruction. In Addison's anæmia the degenerated red blood discs, so lavishly poured out by the bone marrow, are prevented from accumulating by the enhanced activity of their destructors. In leukæmia the decrepit white cells are hoarded away in the spleen and in nooks and crannies in other parts of the body until they disintegrate and their débris litters the blood-stream.

In all other fundamentals of origin, cause, course, and treatment there is no essential difference between Addison's anæmia and leukæmia, and the explanation now brought forward does away with the necessity for attempting to account for these two similar disorders in totally different ways.

It is now recognised that leukæmia is a neoplastic disorder, in no essential respects different from other neoplasias. Some 12 years ago a book[1] was written with the object of showing that there is a large and important class of diseases characterised by the return of cells or tissues to a quasi-embryonic state and by possessing certain other basic characters of form and function in common. Among these were Addison's anæmia, leukæmia, and the cancers, and the evidence that has been collected since this book was written has tended to confirm the truth of this theory. Thus what can be more suggestive than some recent results of unintended experiments with radium and X rays? Under their influence the skin may become prematurely senescent and cancerous, the blood organs leukæmic or affected with Addison's anæmia.

AN INVESTIGATION OF SECONDARY INFECTIONS COMPLICATING PULMONARY TUBERCULOSIS

AMONG SANATORIUM PATIENTS.

By R. C. WINGFIELD, M.B., B.Ch. Oxf.,

MEDICAL SUPERINTENDENT, BROMPTON HOSPITAL SANATORIUM, FRIMLEY.

The problem of the clinical importance of secondary infections in pulmonary tuberculosis is one to which a great deal of time and work has been devoted; the generally accepted conclusion has been reached that all cases of open pulmonary tuberculosis are secondarily infected, and that this secondary infection becomes more obvious and of greater clinical importance if the patient is living in a town, tending to disappear when the patient is placed under sanatorium conditions. The disappointing results of the use of vaccines as a method of treatment have led physicians to abandon them as a routine and to regard secondary infection as an unavoidable complication in a large percentage of cases. The grave disturbances of health caused by the infection of areas of abnormal lung tissue by pyogenic organisms cannot be denied when the course of the ordinary case of simple bronchiectasis is considered; yet in pulmonary tuberculosis, with equally large abnormal lung areas thus infected, this complication is often overlooked, or, if recognised, ignored, because of uncertainty as to its clinical importance in an individual case and the lack of success in treating it.

It is my object in this article not to advocate the administration of autogenous vaccines in every case of pulmonary tuberculosis where the character and bacteriology of the sputum lead one to suspect a secondary infection, but rather to try to show that there are certain types of cases in which, even under sanatorium conditions, secondary infection of clinical importance can be recognised and will respond to autogenous vaccine treatment.

The Problem of Lack of Progress.

I am convinced that a careful consideration on the lines that I am going to suggest, of all cases that "hang fire" under sanatorium conditions, would suggest a secondary infection, amenable to vaccine treatment, as the cause of the lack of progress in a certain percentage; and further that this percentage could be recognised with sufficient certainty to warrant the lengthy procedure of the preparation and administration of a vaccine with a reasonable hope of success.

The chance that two or three of these cases came under my notice together emphasised the problem of their lack of progress, and the fact that they had so many features in common induced me to group them together for further investigation. A detailed description of one case will suffice for it to be recognised by anyone who has had charge of a tuberculosis sanatorium as one with which they are quite familiar.

Female, aged 32, suffering from pulmonary tuberculosis with tubercle bacilli in the sputum; disease of three years' duration; under sanatorium treatment for about the last six months. Gross disease of left lung, with well-marked fibrosis, some cavitation, extensive pleural adhesions, and a few small deposits in the right

TABLE I.

SERIES I.—*Cases with Secondary Infection of Clinical Importance Treated with Autogenous Vaccines.*

P.A. = Pyrexial attacks.

Nature and duration of disease.	Sputum organisms in order of preponderance.	After-history.
1. C. G. T.B. +. 3 years. Extensive one-sided lesions. P.A. every 4–5 weeks. (See Charts 1 and 2.)	Two types strep. Vaccine dosage 5–50 mill.	Disappearance of sputum. One mild P.A. in 8 months. Gain of weight. Able to do hard work.
2. O. G. T.B. +. 2 years. Extensive disease r. l. lobe. Offensive sputum. P.A. at irregular intervals. (See Chart 3.)	Pure strep. Vaccine dosage 5–50 mill.	Diminution and disappearance of fœtor from sputum. Left too soon to show any further result.
3. S. H. T.B. +. 4 years. Dense disease l. base. P.A. very acute every 6 weeks.	Two types strep. *Staphylococcus aureus.* Vaccine mixed strep. Dosage 5–50 mill.	No further P.A. at sanatorium. Sputum decreased. Able to return to work in town and continue for 15 months. Previously too ill to work for 3 years. Relapsed again after 15 months.
4. W. G. T.B. +. 2 years. Extensive l.-sided disease. P.A. every 4–5 weeks.	Two types strep. *Staph. aur.* Vaccine mixed strep. Dosage 5–50 mill. Two courses.	During first course of vaccine P.A. disappeared. Sputum unaltered. Attacks started again and controlled by second course of vaccine, but general progress of disease unaltered. Patient went slowly down-hill.
5. R. E. T.B. +. 2 years. Dense disease r. side, apical cavity. P.A. short and without symptoms.	Strep. 1 and 2. *M. catarrhalis. Staph. aur.* Vaccine mixed strep. Dosage 5–50 mill. *M. catarrhalis.* Dosage 20–200 mill.	Cessation of P.A. and levelling of a rather marked temperature swing. Disappearance of sputum.
6. W. R. T.B. +. Extensive lesions both lungs. Previous sanatorium treatment. Rather long drawn out P.A.	*Staph. aur.* Strep. Vaccine mixed *Staph. aur.* and strep. Dosage 5–50 mill. strep., 50–500 mill. staph.	Diminution in intensity and then disappearance of P.A. Disappearance of sputum. Gain in weight. Ability to do full day's work.
7. R. W. T.B. +. 5 years. Extensive lesion l. lung, following an operative broncho-pneumonia. Rather prolonged bouts of pyrexia, 7 days.	Strep. 1; *M. catarrhalis,* strep., 2; *Staph. albus.* Vaccine mixed catarrhalis and 2 strep. Dosage 50–500 mill.	Diminution of amount of sputum, becoming less purulent. P.A. almost negligible and very short, 1 or 2 days. Still under treatment.
8. W. B. T.B. +. 1 year. Extensive l.-sided disease. P.A. very acute and apparently connected with weather conditions.	*M. catarrhalis.* Strep. 1 and 2. *Staph. albus.* Vaccine mixed catarrhalis and both strep. Dosage 50–500 mill.	Diminished sputum and a great feeling of increased well-being, but vaccine treatment too short for accurate conclusions.
9. V. B. T.B. +. 3 years. Pyrexial bouts 5 in 8 months. Rather drawn out. Large scattered lesions both lungs.	*M. catarrhalis.* Strep. 1 and 2, hæmolytic. *Staph. albus.* Vaccine mixed catarrhalis and both strep. Dosage 50–500 mill. of each.	Gain in weight. P.A. 3 in 5 months, much slighter. Sputum unaltered. Feels much better. Doubtful as to result of vaccine.
10. W. S. T.B. +. 4 years. Extensive scattered disease l. lung. No definite evidence of cavitation. Rather prolonged P.A.	*Staph. aur.*, hæmolytic. Strep. 1, hæmolytic. *M. catarrhalis.* Vaccine mixed staph. and strep. Dosage 50–500 mill.	No P.A. since commencement of vaccine. Sputum decreased. No gain of weight for 3 months previous to vaccine. Gain of 8 lb. during next 3 months. Able to do full carpenter's work.
11. J. W. T.B. +. 2 years. Extensive disease r. lung with deposits on left. Very frequent P.A., accompanied by much bronchitis.	Strep. 1 and 2. *Staph. aur.* Vaccine mixed strep. Dosage 5–50 mill.	Diminution in intensity and number of P.A.; after full course of vaccine well enough to do light work.

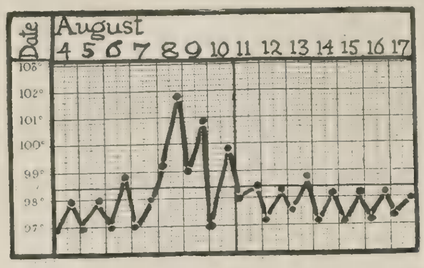
TABLE II.

SERIES II.—*Other Cases with Secondary Infection of Slight or No Clinical Importance Unaltered by Vaccine Administration.*

Nature and duration of disease.	Sputum organisms in order of preponderance.	After-history.
1. C. P. T.B. +. Dense r. lung disease with apical cavity. Long bouts of fever, accompanied by hæmoptysis.	Strep. 1 and 2. *Staph. albus.* Vaccine mixed strep. Dosage 5–50 mill.	No definite result during course of vaccine, but improved later.
2. K. M. T.B. +. Gross disease with cavitation l. lung after expansion of lung collapsed by artificial pneumothorax. No definite P.A., but long bouts of slight fever. (See Chart 4.)	*Staph. aur.* Strep. 1 + and 2. Vaccine mixed staph. and strep. Dosage 5–50 mill. strep., 50–500 mill. staph.	No result.
3. R. O. H. T.B. +. 2 years. Gross disease both lungs with apical cavitation. Continuous slight fever with exacerbation.	*M. catarrhalis* + Strep. 1 + *Staph. aur.* Vaccine mixed catarrhalis. Dosage 20–200 mill. and 5–50 mill.	No result.
4. R. T. T.B. +. 18 months. Extensive lesions r. lung, complicated by asthma and smouldering P.A.'s influenced by weather conditions.	*M. catarrhalis.* Strep. 1. Friedländer's bacillus, very few. Vaccine mixed catarrhalis. Dosage 50–500 mill. and 50–500 mill. strep.	No result.
5. F. E. T.B. +. 2 years. Dense disease r. lung with apical cavitation. Pyrexial bouts long drawn out.	Strep. 1 and 2. *M. catarrhalis,* very few. Vaccine mixed strep. Dosage 5–50 mill.	No result.
6. A. M. T.B. +. 4 years. Lesion extensive and dense both lungs, with cavitation in lower lobe. Continuous pyrexia.	Strep. *Staph. aur.* Vaccine strep. Dosage 5–50 mill.	No result.
7. F. F. T.B. +. 4 years. General condition and progress excellent. Extensive r. lung lesion. Sputum very excessive and purulent. Vaccine given to control sputum.	Strep. 1. + + +. Vaccine of strep. Dosage 5–50 mill.	Slight diminution in sputum.
8. H. T. T.B. +. 1½ years. Extensive r. lung lesion. General condition and progress very good. Influenced by weather conditions.	Strep. 1 and 2. *Staph. aur. M. catarrhalis,* fairly equal proportions.	No vaccine given.
9. S. D. T.B. +. 7 years. Very dense and extensive lesion l. lung with apical cavitation. General health and condition excellent. On full work (country). Sputum ʒi daily, purulent.	Strep. 1, pure culture.	No vaccine given.
10. A. D. T.B. +. 6 months. Slight pyrexia very frequently, but not in definite attacks. General condition good, but no progress.	*Staph. aur.* Strep. 1 and 2, very few. Vaccine dosage, staph. 100–1000 mill.	Vaccine only just started.
11. J. M. T.B. +. 1 year. Disease slight in both lungs. Continuous pyrexia.	Strep. 1 and 2. Vaccine mixed strep. Dosage 5–50 mill.	No result.
12. A. H. T.B. +. 1 year. Dense disease r. lung, collapsed completely by artificial pneumothorax. No recognisable disease in left. General health and condition excellent. On full work. Sputum daily purulent.	Strep. 1 and 2. *Staph. alb.*, a few. Vaccine of strep. 1. Dosage 50–500 mill. for control of sputum.	Vaccine only just started.

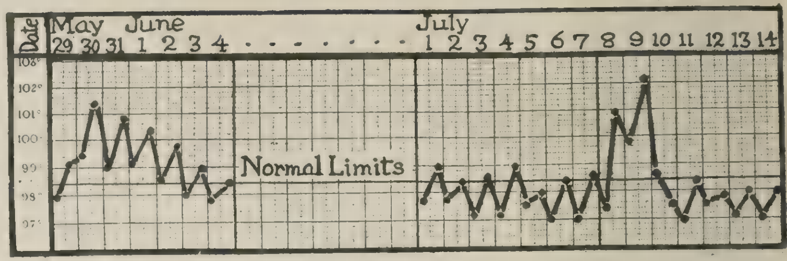
lung. Temperature and pulse within normal limits. General condition good and weight steady. Exercise to the amount of four to six miles daily. Sputum about 1 oz. daily; purulent; tubercle bacilli present. At recurring intervals of four to five weeks this patient suffered from a pyrexial attack lasting four to six days, with a sudden onset and temperature reaching between 100°–103° F.; subsiding by lysis. The attack was accompanied by general body pains, headache, malaise, and an increased quantity of sputum. The patient remained in this condition, neither gaining or losing weight nor making any progress for from four to five months. On bacteriological examination of sputum a streptococcus was isolated and was regarded as the predominant organism of the secondary infection. An autogenous vaccine was made and administered. The patient's condition during the next eight months was as follows: One mild pyrexial attack, disappearance of sputum, and an average gain of 2 lb. per month, and an ability to work five or six hours daily on a small poultry-farm without any constitutional symptoms. At the end of this time, feeling perfectly restored to health, but with physical signs in the lungs practically unaltered, the patient elected to leave the country and to go back to London. There was an immediate return of sputum and of pyrexial attacks, with exacerbation of all the symptoms. I believe the patient has been almost entirely bed-ridden since, during a period of 14 or 15 months.

CHART 1.



Showing a typical pyrexial attack. (Series 1, Case 1.)

CHART 2.



Showing two typical pyrexial attacks. (Series 1, Case 1.)

Features Common to this Type of Case.

Comparing this case with others whose clinical history was similar, it was noticed that they had the following features in common: (1) Old-standing lesions; (2) periodical pyrexial attacks, with sudden onset and short duration, from which they apparently completely recovered; (3) extensive lesions, usually with evidence pointing to cavitation—that is, large areas of abnormal lung and bronchial surfaces; (4) streptococci, usually predominant among micro-organisms isolated from their sputa; (5) pyrexial attacks, usually controlled or materially altered by the administration of autogenous streptococcal vaccine.

TABLE III.—*Bacteriology of Sputum.*

Case.		(*a*) Before vaccine.	(*b*) After vaccine.
W. R.	Series 1 Case 6 ..	*Staph. aur.* Strep. 1.	Strep. 1 and 2. *Staph. albus.*
K. M.	Series 2 Case 2 ..	*Staph. aur.* Strep. 1 and 2.	Strep. 1 and 2. *Staph. aur.*
A. M.	Series 2 Case 6 ..	*Staph. aur.* Strep. 1.	*Staph. aur.* Strep. 1.

A bacteriological examination of many other cases in the sanatorium with extensive lesions was undertaken at the same time, and vaccines were prepared from the micro-organisms isolated; but it will be seen from the detailed reports on the previous page that only in those cases where the above five points were exhibited did vaccine treatment give satisfactory results, although the type of secondary infection was the same in both series of cases.

Auto-inoculation or Secondary Infection?

It might be argued that these pyrexial attacks, of which typical examples are illustrated in Charts 1, 2, and 3, were due to tuberculous auto-inoculations, but they never coincided with any increased exercise, nor did a careful questioning of the patient bring to light any of the usual reasons for a pyrexial attack. Sudden pyrexia in a hitherto afebrile case, if due to tuberculous infection, can usually be connected with some definite indiscretion or with an extension of disease capable of recognition by physical examination. No gross alteration in the condition of the lung lesion was noted during these pyrexial attacks.

I think it may be suggested that, in the first series of cases, the secondary infection was of such a nature as to have a definite effect upon the patient, that in time it would have undermined the general resistance and the specific resistance to tuberculosis and caused an increase in the activity of the tuberculous infection, and that appropriate autogenous vaccine treatment was the best method of dealing with it; while in the second series of cases, although the bacteriological findings of the sputum were similar to the first series, there was no definite evidence that it was this infection, rather than the tuberculous infection, which was causing the pyrexia, and that, at any rate, it was not amenable to vaccine treatment.

Apparently we may expect to find much the same bacteriological content in any purulent sputum from a patient with an extensive lesion, and no conclusions can be drawn from this alone as to the importance of the secondary infection, which must be estimated mainly from the clinical data. It is interesting to note that vaccine treatment, whether successful or not, although followed by diminution or disappearance of sputum in some cases, did not materially alter the bacteriological content of the sputum if it still persisted.

Bacteriological Examination of Sputum.

A suitable method had to be found whereby accurate bacteriological examination of sputum could be made. Prof. L. S. Dudgeon very kindly gave me full particulars of a method which he had been using for some time which had given very satisfactory results, and this method was used in practically all cases.[1]

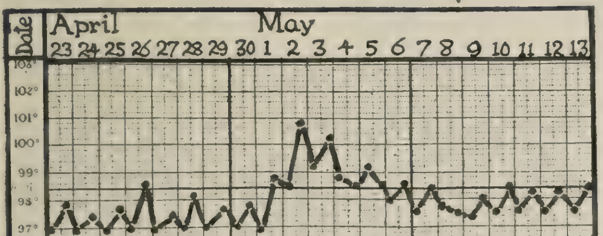
All the work was done inside a large glass box provided with silk side curtains and armholes, serving as a protection to the worker and also a preventer of air-borne contamination. Morning sputum was collected, with precautions to avoid contamination &c., and spread on a sterile tile of unglazed porcelain, 3 in. by 3 in. This was left for 20 minutes, scraped off in a viscous condition, respread on a second tile, and left till dry and powdery. Two casein-digest or meat agar-digest plates, adjusted to an alkalinity of pH 7·6, to which a small quantity of fresh human blood had been added, were prepared, and some of the powdery sputum was taken on the point of a knife, shaken on to these plates, and distributed evenly over the surface with a sterile glass rod. These plates were examined after 24 hours and showed a fine growth of discrete colonies, easy to pick off for examination and subculture. A detailed examination was made of all the different micro-organisms growing, with a note as to the relative quantities of each, and from the first plate the composition of the proposed vaccine was determined. The only drawback experienced in using this method was the difficulty during the summer of excluding air-borne contamination, which probably occurred during the exposure of the sputum while drying on the porcelain tiles. The micro-organisms found were: (*a*) streptococci, (*b*) staphylococci, and (*c*) *Micrococcus catarrhalis*. These were present in various proportions in different specimens. It is interesting to note that in no case was the pneumococcus found, although the morphology of the micro-organisms forming some of the colonies suggested it, but these were always proved on subculture to be streptococci; I think it may be taken that the pneumococcus was not present, for Urquhart,[1] using this method and these media, obtained free growth of the pneumococcus in pulmonary infection, both acute and chronic. Friedländer's pneumo-bacillus, or any of the mucous-capsulatus group only appeared once; from previous experience of bacteriological examination of sputa in London I have seen this type of organism in three cases of pulmonary tuberculosis which responded to vaccine treatment.

---

[1] Urquhart: Journal R.A.M.C., March, 1922. Wordley: Journal of Hygiene, July, 1921.

A determination of the micro-organisms present in the specimen having been made, fuller attention was given to the streptococci as the most likely to be of importance in the secondary infection. These appeared to be mainly of two types: (1) long chains of coarse cocci, and (2) short chains of fine cocci. These could readily be recognised by the difference in their cultural characteristics. They were isolated and tested for hæmolytic power and pathogenicity to guinea-pigs. Except in very few cases they proved to be non-hæmolytic when grown in peptone water with fresh human blood corpuscles added, even though they occasionally showed signs of hæmolysis in the original blood-agar plates, but this phenomenon was also noted with some of the *Staphylococcus aureus* colonies. They were non-pathogenic to guinea-pigs (intraperitoneal inoculation) in all cases. Some strains were injected into rabbits intravenously and produced no effects.

CHART 3.

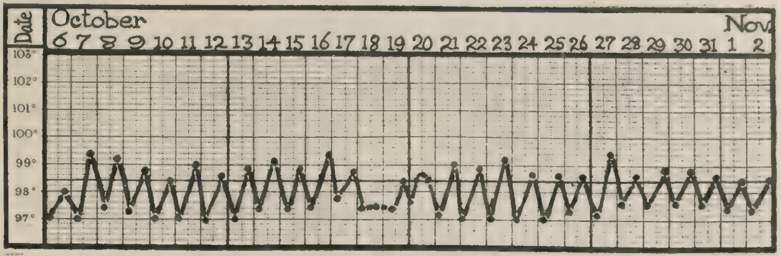


Showing a typical pyrexial attack. (Series 1, Case 2.)

Preparation of Vaccines.

The vaccines were first prepared by using a 24-hour broth culture, centrifugalising, washing, and re-emulsifying the organisms, and killing them by heat. Of these vaccines the dosage used was small, beginning at 5 million and working up to 50 million. Latterly I have used a method suggested to me by Prof. Dudgeon, in which the vaccine is prepared by washing the culture grown on agar slopes with 1 per cent. formalin in normal saline solution, allowing the formalin to kill the micro-organisms, counting, and making a suitable dilution from this. Vaccines prepared by this method are capable of being used in much larger doses, beginning at 50 or 100 million and working up to 500 or 1000 million. The details of the two series are given in the accompanying tables, setting forth the type of case, the type and dosage of the vaccine, and the course of the case after vaccine administration.

CHART 4.



Case of pyrexia unaltered by vaccine. (Series 2, Case 2.)

The size of the initial dose depended on the method of preparation. Injections were given every five to seven days provided that there was no fever and no premonition of a pyrexial attack. The dose was gradually increased and reactions were avoided as far as possible. If reactions occurred the vaccine was not given until this had entirely subsided and recommenced at a smaller dose and increased more gradually. If a case improved under treatment and relapsed, treatment was begun again. About three or four months' duration of treatment was aimed at, but unfortunately this was often curtailed by the patient having to leave the sanatorium. The ordinary sanatorium routine treatment was not modified during the vaccine treatment, the patients being put through such a course of graduated labour as their condition warranted.

The results of treatment of tuberculous patients of the working class in London, from which class these patients came, are influenced strongly by so many personal, social, and economic factors that I am doubtful whether any very valuable conclusion can be drawn from the history of the cases after their return to ordinary life. The results would be certainly disappointing, and I think they can only be relied on for patients of this class while the patients are under institutional conditions.

I wish to record my indebtedness to the Medical Research Council, with whose help this work was carried out; to Prof. Dudgeon, for advice and help throughout; and to Mr. L. G. Wilson, for his many months of assistance in the laboratory.

INFANT CARE.—A course of advanced lectures on Infant Care for infant welfare workers, teachers, and mothers will be held at 117, Piccadilly, London, W. 1, on Mondays, from 6 to 7 P.M., from Jan. 22nd to Feb. 26th, and at the Infants Hospital, Vincent-square, Westminster, London, S.W., from March 5th to April 23rd. The first half of the course will be given by Dr. H. C. Cameron and the second half of the course by Dr. Eric Pritchard.

LONDON INTER-COLLEGIATE SCHOLARSHIPS BOARD.—Twenty-three scholarships and exhibitions of an aggregate total value of about £3035, open to men and women, and tenable in the faculties of arts, science, medical sciences, and engineering of University College, King's College, East London College, and Bedford College will be offered for competition on May 1st. Fifteen medical entrance scholarships and exhibitions of an aggregate total value of about £1530, tenable in the faculty of medical sciences of University College and King's College, and in the medical schools of Westminster Hospital, King's College Hospital, University College Hospital, the London (R.F.H.) School of Medicine for Women, and the London Hospital will be offered for competition on June 26th. Full particulars and entry forms may be obtained from the Secretary of the Board, Mr. S. C. Ranner, Medical School, King's College Hospital, Denmark Hill, London, S.E. 5.

SULFARSENOL IN THE TREATMENT OF SYPHILIS

AND OF SOME OF THE COMPLICATIONS OF GONORRHŒA.

BY F. CARMINOW DOBLE, M.R.C.S. ENG.,
TEMPORARY CAPTAIN, R.A.M.C.; OFFICER IN CHARGE GONORRHŒAL DIVISION, MILITARY HOSPITAL, ROCHESTER ROW, S.W.

SINCE my last article on Sulfarsenol appeared in THE LANCET over two years ago,[1] the medical press in America and practically every country in Europe has published the result of the treatment of syphilis by this drug, but the English medical press has been almost silent on the subject.

Therapeutic Action.

Very few experts will disagree with the statement which has always been maintained by Colonel L. W. Harrison, that the therapeutic effect of any of the arsenobenzol group is always better when given intramuscularly or subcutaneously, than when the same dose is given intravenously. The only one of the arsenobenzol compounds at present on the market which can be given by injection into the muscles or subcutaneous tissue without causing great pain is sulfarsenol. Besides the increased therapeutic effect, there is no need for the patient to starve before an injection can be given. This starvation, besides being objected to by the patient, also renders him more liable to jaundice. The results which many others besides myself have obtained with sulfarsenol have been uniformly good.

Effect of Sulfarsenol on Spironema Pallidum.

The disappearance of *Spironema pallidum* from the lesions, as shown by the dark ground examination 24 and 48 hours after an injection of this drug, compares very favourably with intravenous injections of the same dose of neosalvarsan and neokharsivan. This was not my experience in the few cases I had treated, when I wrote my last article, but possibly the potency of the drug may have been increased in the meanwhile. In only one case was the spironema found on the third day.

Effect of Sulfarsenol on the Complement-fixation Test.

The clinical results and the effect on the complement-fixation test of the blood equals those of any other drug. The action on the cerebro-spinal fluid is not so marked as that obtained by silver-salvarsan. Even most of those cases whose blood shows what Colonel Harrison calls "an inveterate Wassermann reaction" can in time be made to give a negative result.

Sulfarsenol Treatment in Cases that React Badly to other Forms of "914."

I have treated a dozen or more cases who have reacted badly to the other arsenobenzol compounds, and who have been refused treatment by syphilologists on account of dermatitis, jaundice, or other complications. These unfortunate individuals could only get treated with potassium iodide and mercury. By starting with small doses of sulfarsenol and gradually increasing the dose, I found that the lesions cleared up and the complement-fixation test became negative and remained so. One of these cases had been taking mercury for over a year and still had moist papules on his scrotum. His mouth was in a dreadful state from mercurial stomatitis. He was in a suicidal frame of mind until his lesions rapidly cleared up and he realised that he was being cured.

Clinical Side Effects.—A Herxheimer reaction occurred in under 1 per cent. of all the cases. It was never severe and, apart from two instances, was only found in cases of advanced secondary syphilis with a well-marked rash, treated with an intravenous injection. These two instances occurred after a subcutaneous injection. I have never seen any clinical side effects, and have only heard of one, that was a slight vasomotor disturbance which took place shortly after an intramuscular injection. It only lasted a few seconds and never occurred again, although larger doses of the same batch were given subsequently.

Primary Cases.

Dark-ground *S. pallidum.*—Cases 1 and 2: Present 24 and absent 48 hours after first injection. Case 3: Abundant. Present 24 and absent 48 hours after first injection. Cases 4 and 5: Abundant. Absent 24 hours after.

W.R. = Wassermann reaction. S = Sulfarsenol. NAB = Novarsenobillon. NK = Neokharsivan. NS = Neosalvarsan. Iv = Intravenously.

Treatment of Infants and Pregnant Women.—In the treatment of infants there is no drug to touch sulfarsenol. Full courses can be given without fear of severe consequences or fatal results, as long as the dose is regulated by the body-weight of the infant. Pregnant women can be treated right up to the birth of the child, and then mother and child can be treated separately.

Cause of Pain after Injections.—Some batches give more pain than others, but it is never very severe. The distilled water that the drug is dissolved in must be absolutely fresh and sterile. The water is to blame in cases with high temperature and with the great pain sometimes complained of in the site of the injection.

Routes of Injection.

It seems quite unnecessary to give intravenous injections of sulfarsenol in the treatment of syphilis, a larger dose has to be given, the patient has to starve before, and starve and rest after each injection;

Dark-ground *S. pallidum.*—Case 1: Present. Absent 24 hours later. Case 2: Present 24 and absent 48 hours after first injection. Case 3: Absent. Case 4: Abundant. Present 24 and 48 hours later. Case 5: Present. Absent after.

* Then had 3 × 0·42 g. S., 4 × 0·6 g.

this is bound to interfere with his or her work, and possibly results in the treatment being interrupted or even stopped altogether. With the other methods of injection, especially the subcutaneous, the patient is able to carry on his ordinary work without the fear of anything untoward happening. Any form of exercise can be taken directly after an injection.

Results of Treatment.

The accompanying notes on five cases of primary and five of secondary syphilis show the result of treatment by sulfarsenol. Space limits the details, but they are enough to give a very good idea of the therapeutic effect of the drug. In tertiary syphilis the results are equally good, but again space precludes one from showing them in this article. It will be seen that in some of the cases a preliminary intravenous injection of neosalvarsan, neokharsivan, or N.A.B. has been given. This was done with the idea of rendering the patient non-infectious in the quickest possible time. It now appears evident that sulfarsenol has quite as lethal an action on the spironema as any of the other arsenobenzol compounds used. All the injections were given by the intramuscular route, unless otherwise stated. The cases that only had a few injections were either transferred to another hospital or were demobilised and instructed to attend a civil clinic. All cases were treated concurrently with intramuscular injections of mercury.

It will be seen from the following table what is the effect on the Wassermann reaction on cases of primary and secondary syphilis after the first course of 4·2 g. sulfarsenol. The total number of cases of which I could obtain the figures was 230.

—	W.R. – before treatment.	W.R. + before treatment.	W.R. + after 4·2 g.
Primary ..	60 per cent.	40 per cent.	0
Secondary ..	0	100 per cent.	12·5 per cent.

The Complications of Gonorrhœa.

For the treatment of the complications of gonorrhœa the intravenous route is the best. I have tried this drug on patients with most of the complications that are to be met with, such as arthritis, rheumatism, hyperkeratosis, and epididymitis. The results were remarkably good, but the effect in epididymitis was extraordinary. I have treated nearly 300 cases of this complication with sulfarsenol, and have never failed to stop the pain in a few hours and reduce the temperature and swelling in a few days, the average time in bed being 4·5 days. Patients previously in very great pain who had to be given morphia, slept peacefully a few hours after an injection of sulfarsenol. It has been my custom to give a dose of 0·12 g., followed in 48 hours by an injection of 0·18 g. In all but four cases no more injections were necessary. In these cases the temperature went up a day or so later, and the pain returned. I then gave an 0·18 g. followed by another injection 48 hours later of 0·3 g., with the result that the temperature dropped to normal and the pain disappeared. They did not relapse again. (See chart.) These cases of epididymitis were free from gonorrhœa in the average number of days of cases with no complications.

All the cases were treated either privately or at the Military Hospital, Rochester-row. For permission to publish the results of the hospital cases my best thanks are due to the commanding officer, Major A. T. Frost, and also to Major G. Petit, officer in charge of the syphilis division.

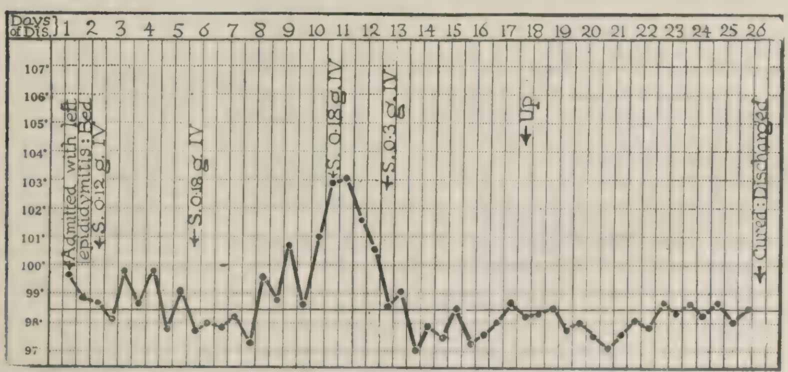

Chart showing temperature of case requiring more than two injections of sulfarsenol. After two further injections the temperature fell to normal and the pain disappeared. No relapse followed. IV = Intravenous.

THE NON-DIARRHŒIC TYPE OF CŒLIAC DISEASE:

A FORM OF CHRONIC FAT-INDIGESTION IN CHILDREN.

By REGINALD MILLER, M.D., F.R.C.P. Lond.,
PHYSICIAN TO PADDINGTON GREEN CHILDREN'S HOSPITAL; SENIOR PHYSICIAN TO OUT-PATIENTS, ST. MARY'S HOSPITAL, LONDON;

WITH

HERBERT PERKINS, F.R.C.S. Eng.,
PATHOLOGIST TO PADDINGTON GREEN CHILDREN'S HOSPITAL.

The objects of this communication are, first, to describe a group of young children who show certain symptoms and who fail to thrive owing to an inability properly to absorb their dietetic fat, and yet who differ from the ordinary cases of cœliac disease in that they show neither pallor of the stools nor (in its popular sense) diarrhœa; secondly, to give the evidence for regarding them, in spite of these notable differences, as examples of cœliac disease in mild form; and finally, in the light of these cases to offer some comments on the characteristics of fatty stools in general and on the pallor of cœliac stools in particular.

To refer for a moment to the terms of my title, I mean by "cœliac disease" a disorder showing as its essential feature malabsorption of fat, which disability is not referable to gross disease of the pancreas, liver, or intestine. I have elsewhere produced evidence to show that the "disease" is, as Gee and others conceived it to be, essentially a digestive fault and not an organic disease.[2] The term diarrhœa is used in its popular meaning of loose and frequent stools, and not in the stricter sense of merely excessive intestinal elimination; the latter is present in the group of cases I am describing.

Classical (Diarrhœic) Type of Cœliac Disease.

The symptoms of cœliac disease usually make their appearance first in the second year of life and often develop rapidly. In classical form they consist of (1) enlargement of the abdomen without signs of organic abdominal disease; (2) the passage of stools which are large, pale, unformed, obviously fatty, very offensive, and more frequent than normal, the diarrhœa at times being very severe and leading to grave illness and wasting; (3) on analysis the percentage of fat in the fæces is found to be very much above the normal for the child's age and diet, such figures as 30, 50, or even 80 per cent. being obtained; and the fæcal fat is thus distributed: fatty acid in greatest excess, soaps in considerable excess, and neutral fats in small proportions only; (4) retardation of physical development. To these most important symptoms may be added as frequently present (5) fickleness of the appetite with periods of refusal of food; and (6) some persistent low fever or bouts of rather higher temperature.

Non-diarrhœic Type of Cœliac Disease.

The non-diarrhœic form resembles the classical type in most particulars, but it must be emphasised that it resembles (and, indeed, constitutes) a *mild* variety of the disorder. Thus it appears to start at about the same age, but it develops so insidiously that its onset is dated with difficulty. The abdomen is enlarged, definitely but so moderately that it may be regarded as a peculiarity of the child rather than as an indication of disease. There may be some retardation of growth, or, more commonly, merely a failure to gain any weight even for months at a time. Anorexia and fever may be present. The stool, as in the ordinary type, contains a considerable excess of fat, but in appearance and composition it is very different from the classical cœliac stool. In both types of the disorder the stool is large, but in the non-diarrhœic type it is formed, well-coloured (and the colour deepens on exposure), and not particularly offensive. In frequency there may be one, occasionally two, daily. The size of the stool is increased because it contains an abnormal amount of fat (20–50 per cent.). The difference in its appearance from the classical cœliac stool seems due to a difference in the distribution of the fæcal fat; for, instead of the greatest proportion of the fat being in the form of fatty acids, showing as masses of white crystals under the microscope, in the non-diarrhœic type the fat is chiefly in the form of soaps which show microscopically as pigmented flakes. Thus in this type of the disorder, although on very close examination a cut surface of the fæces may appear greasy in texture and perhaps rather grey in colour, the stool as a whole on ordinary inspection looks very normal in consistency and colour though rather large in size. It will be argued later that the soaps take up the bile-pigment rendering the stool coloured, whereas in the presence of a great excess of fatty acids the pigment is masked.

Table of Comparison between the Classical and Non-diarrhœic Types of Cœliac Disease.

—	Ordinary type.	Non-diarrhœic type.
Onset.	Rapid.	Insidious.
Symptoms.	Severe.	Mild.
Stools.	Very large. Unformed. Very pale. Offensive. Obviously fatty. Frequent (2–8).	Large. Formed. Well coloured. Not offensive. Greasy on section. Not frequent (1–2).
Fæcal fat.	Great excess (30–80 %) Mainly fatty acids.	In excess (20–50 %). Mainly soaps.

Cases of Non-diarrhœic Type.

The following are cases of non-diarrhœic type:—

Case 1.—Molly C., aged 4 years, referred to me by Mr. G. Elphick for attacks of fever. One year ago her tonsils were removed for local reasons. Three months later she had a bad cold in the head which was followed by attacks of fever lasting from three to five days, and starting off with a temperature of 103° F. After three months of these attacks she was found to have a chronic streptococcal maxillary antrum. This was drained and for the next three months no febrile attacks occurred. However, for the last three months they had again been present and at the time of my first seeing the child they were occurring about every three weeks. They were not accompanied by either constipation or diarrhœa, but they were preceded by a day or so during which the child appeared sallow, refused her food completely, and had a coated tongue. No cause for these febrile attacks could be traced. During the last six months she had lost weight (3½ lb.) and had ceased altogether to grow.

Condition on Examination.—On seeing the child I was at once struck by her doll-like appearance. In weight she was 34 lb., and in height 40 in., but she looked more *petite* than these figures suggest. Her abdomen was distinctly large, showing particularly when she stood up, and I was told that it had "always" been so; at all events, at the age of 2 it was definitely prominent. The lack of growth, the enlargement of the abdomen, the very poor appetite with periods of refusal of food, and the attacks of unexplained fever together made me consider the possibility of cœliac disease. I went, therefore, carefully into the question of the stools but could obtain no history of diarrhœa or pale stools at any time. On the other hand, the statement was volunteered that the stools were always large and would remain so even after a day in which almost no food was taken. The bowels were opened once every day without fail; very occasionally twice. Before inspecting the stool I inquired into the diet. Several diagnoses had been made on the case, ranging from hysteria to abdominal tuberculosis, and on the latter hypothesis the diet at that time, in addition to ordinary food in as large quantities as the child could be prevailed upon to take, contained milk and cream from a Jersey herd on the parents' estate, and also cod-liver oil. Yet the stool was perfectly formed and quite good in colour.

Fat Analyses.—Considering the diet I felt that the appearance of the stool quite negatived the possibility of cœliac disease in such a stage as to be productive of symptoms. But when the fæces were being manipulated for the purpose of a bacteriological examination it seemed that they were rather greasy and under the microscope many coloured flakes of soaps were seen, so that an analysis for fat was made. This showed no less a proportion of fat than 56·8 per cent., of which 57 per cent. was in the form of soaps. Protein digestion was good, and there was no evidence of catarrh or inflammation of the bowel. The bacteria were normal, mainly coliform organisms with a few streptococci. No other possible cause for pyrexia could be found, but I did not yet feel certain that the diagnosis of cœliac disease was correct. I remembered that I was seeing the child during an apyrexial period and that the amount of the fat in the diet was very excessive. I therefore had another analysis made when the cream and cod-liver oil had been omitted from the diet. The percentage of fat in the stools only sank from 56·8 per cent. to 52 per cent. (analysis B). This looked still more suspicious. I therefore had all milk skimmed by hand (gravity method) and all butter omitted from the diet. This brought the percentage of fat in the fæces down to 34 per cent. (analysis C). This high percentage on a low fat diet I considered diagnostic, and this opinion was confirmed by the improvement in the child's complexion, spirits, and appetite, and by the cessation of the feverish attacks.

Result of Treatment.—Proceeding then to find her optimum diet in fat, I had all her milk machine-skimmed. The percentage of fat in the stool dropped to 28 per cent. and the administration of bile-salts reduced it further to 24·8 per cent. (analyses D and E). Further improvement was shown in the appetite and in every way the child seemed extraordinarily better. But on this diet she lost a little weight. Some more fat was therefore added to the diet and weight was gained (analyses F and G). During the ten months of treatment the child's improvement has been remarkable and is steadily maintained. There have been no febrile attacks at all. She has gained 5¼ lb. in weight and has grown 3 in. She now eats with relish and mentally has altered into a bright cheerful child. In January, 1923, the stool contained 22% of fat, of which 70·9% was in the form of soap.

CASE 2.—C. B., aged 2¾ years, daughter of a colleague. She was well and strong until 20 months, when she had a feverish attack with greenish, frequent stools, lasting about four days. Since then she has lost her appetite, the abdomen has become big, and for a year she has gained no weight at all and has now stopped growing. She has had three other feverish attacks, one accompanied by a convulsion. The explanation of these attacks has appeared quite obscure. Her appetite is now extremely bad, she chews but will not swallow; a meal will take up to two hours; she will not touch fish, chicken, or meat. The stools are large, one a day, and well coloured. On analysis on ordinary diet, containing 1¼ pints of milk, they were found to contain 31·2 per cent. of fat (analysis A). On diets containing modified amounts of fat they contained 14·7 per cent. and 21·2 per cent. (analyses B and C).

This patient has only been under treatment for six months, It has been instructive to note how regularly any excess of fat in the diet has been accompanied by increase in the size of the abdomen and a complete loss of appetite. After some six weeks of feeding on a very low fat diet the appetite improved wonderfully, and meat and fish are now taken for the first time in the child's life. The administration of bile-salts here seems to have helped the appetite. Growth has restarted (1¾ inches in height and much weight have been gained).

CASE 3.—Male, aged 7, sent to me by Dr. Hunter Dunn. The boy had no definite symptoms except that he was not developing well and was extremely tiresome over his food. He had been diagnosed in Ireland as suffering from rickets and hypothyroidism, and was taking thyroid. I could find no evidence of these conditions except that his abdomen was definitely large and was stated to have been always so. I suggested that the thyroid should be omitted (in agreement with Dr. Dunn) and that the stools be carefully watched for any pallor or signs of excessive fat. After a month I saw the patient again, and in spite of the absence of any naked-eye abnormalities of the stool I had an analysis made for fat. This showed 27·2 per cent., an excessive amount for an ordinary mixed diet. In this case there was no history of diarrhœa or pale stools at any time.

CASE 4.—Male, aged 9, also referred to me by Dr. Hunter Dunn. The prominent symptom here was unexplained fever. Five months previously he had had influenza, and on recovery of his usual health it was found that his temperature remained between 99° and 100°. At times he becomes dark round the eyes and his tongue gets coated, but he does not suffer from constipation or diarrhœa. No signs of disease could be found anywhere, but it was noticeable that his abdomen was definitely large. On analysis of his stools the proportion of fat in the dried fæces was found to be 22 per cent., of which 56·4 per cent. was in the form of soaps.

This case seems less definite than the preceding one, but I am inclined to think it is a very mild example of the non-diarrhœic type. I advised that the use of the thermometer be stopped and that should any worse symptoms develop the fat in the diet be reduced. If the condition of the temperature be disregarded the boy has continued in very good health.

CASE 5.—Male, aged 6, seen with Dr. P. Bott. Child has always been thin and has had a large abdomen since he was 2 years old. His appetite is persistently poor; he is very slow over his food and at time eats very little. His physical development has been slow. His stools are always rather large, but he is not subject to diarrhœa. He has never passed pale stools. Six weeks before I saw him he had had an attack of diarrhœa with fever in Athens, and since then his condition has been less satisfactory than before. His stools are very large but of good colour; the abdomen is definitely large. The stool showed very numerous cysts of *Lamblia intestinale*, but the bacteria were normal. On a mixed diet with one pint of milk the percentage of fat in the fæces was 24·8, of which 67·8 per cent. was soaps. In the absence of any other digestive disturbance this proportion of fat in the stool is distinctly suggestive.

Table of Analyses of Fæces in the Five Non-diarrhœic Cases of Cœliac Disease.

Case.	Analysis.	Per cent. fat in fæces.	Per 100 g. of fæcal fat.		
			Neutral fat.	Fatty acids.	Soaps.
1	A.	56·8	14·1	28·9	57·0
	B.	52·0	13·1	40·8	46·1
	C.	34·0	14·1	21·2	64·7
	D.	28·0	15·1	42·1	42·8
	E.	24·8	16·2	40·3	43·5
	F.	26·8	9·0	40·3	50·7
	G.	34·3	3·1	42·6	54·3
2	A.	31·2	8·9	32·1	59·0
	B.	14·7	23·1	29·2	47·7
	C.	21·2	9·5	37·7	52·8
3	—	27·2	5·9	29·4	64·7
4	—	22·0	7·3	36·3	56·4
5	—	24·8	9·6	22·6	67·8

Evidence for Including these Cases as Cœliac Disease.

Although it has been noted by S. Gee and G. F. Still[3] that the development of cœliac symptoms may be preceded by constipation, yet, so far as I know, a positive diagnosis of the disease has always rested upon the occurrence of the classical cœliac stool, pale, unformed, and frequent. In the present group of cases this characteristic feature is entirely absent, and the question arises whether it is proper to class the non-diarrhœic cases as examples of cœliac disease. As this malady cannot be identified by any specific morbid anatomy or histology [2] the only evidence by which I can support my thesis is necessarily of an indirect kind.

(*a*) *General Similarity.*—The symptoms in the non-diarrhœic form are similar to those of the classical type, though less severe in grade. In my view the essential feature of the disease is the conspicuous failure to absorb fat, a failure out of all proportion to any other impairment of digestion. If this be allowed, then the non-diarrhœic type is essentially the same malady as the diarrhœic cases. In both there is the excessive fat-loss in the stools, the failure to thrive and develop, the enlargement of the abdomen without signs of organic disease, the perversion and loss of appetite, and the tendency to pyrexia. But this similarity depends upon the recognition of the fact that an excessive fat-wastage may be present in the absence of diarrhœa or pallor of the stools. The difficulty that may thus arise in diagnosis is well illustrated in the first case quoted above.

(*b*) *Consideration of Quiescent Stages of Classical Type.*—Further evidence is afforded by the consideration of the diarrhœic cases in their quiescent or convalescent stages. From this two facts emerge: first, that in the non-diarrhœic stages of cases which may have shown typical diarrhœa alba for years, the stools still contain a large excess of fat, mainly in the form of soaps—that is, they are exactly similar to those found throughout in the non-diarrhœic type which I am describing; second, that, contrary to what is usually held to be the case, the disappearance of the classical pale stools by no means indicates that the disease has "cleared up," for analysis will still show a great impairment of fat-absorption. These two important facts are demonstrated in the following cases, the first of which is of considerable interest to me, as it was the first case in which I realised that a stool might be hard, dark, and constipated and yet contain a great excess (39·6 per cent.) of fat.

CASE A.—G. W.,[2] born October, 1909; first seen April, 1920. From the age of 2 until January, 1920, had suffered from typical pale diarrhœa. She could not walk until 4 years old. Has grown little and for three years not at all. Her abdomen has been very large throughout. Since January, 1920, there has been no more diarrhœa, the stools being dark and formed and only one daily. During this time she has improved in every way and growth has restarted. When first seen she was well nourished, but 6 inches below the height proper for her age; in dentition she was two years behindhand; her abdomen was still large. When I first saw her I determined to await a fresh attack of diarrhœa before getting the stools analysed, but none supervened. After waiting nearly a year an analysis was made—i.e., 15 months after the cessation of all symptoms. The report of the stool was as follows:—March, 1921: Stool is very dark brown, hard, and formed; fat in fæces, 39·6 per cent. (neutral fat, 7·0; fatty acids, 28·3; soaps, 64·7 per cent.). During this period of observation, and since, progress has been in every way satisfactory on a slightly low-fat diet. In two years she has grown 6¼ inches.

CASE B.—Doris F.,[1] born October, 1911. This case up to January, 1920, has already been reported. She had suffered from typical cœliac diarrhœa since the age of 2 and has been under my observation since she was 3. At 7 she developed late rickets. In January, 1920, her weight was 24 lb. 6 oz. (normal for age 52 lb.) and height 36½ in. (normal 47 in.). At that time she was given a constant diet containing about 25 g. of fat, and analyses were made of the stools before and after the administration of bile-salts (analyses A and B). Since this time progress has been vastly better and since September, 1920, there has been no diarrhœa at all. Her appetite has greatly improved and there has been good development. In September, 1922, her weight was 47½ lb. and height 42½ in. Nevertheless analyses made March, 1921, and June, 1922 (analyses C and D) show still a considerable excess of fat in the stool mainly in the form of soaps.

Analyses, Case B.

Analysis.	Per cent. fat in fæces.	Per 100 g. fæcal fat.		
		Neutral fat.	Fatty acids.	Soaps.
A	52·4	15·3	75·4	9·3
B	33·7	7·7	49·3	43·0
C	26·8	8·9	37·4	53·7
D	33·2	7·2	40·9	51·9

CASE C.—John R., born April, 1908. Severe cœliac symptoms since the age of 18 months leading to diminished growth. During the last few years has made better progress than previously. For the last two years has been at boarding-school on an ordinary diet and has kept free of diarrhœa, and the stools are persistently well coloured. Growth has been resumed and is at the rate of rather more than 2 in. yearly. An analysis of the stool made in April, 1921, shows still some excess of fat, mainly in the form of soaps. Fat in fæces, 22·8 per cent. (neut. fat, 17·5; fatty acids, 24·6; soaps, 57·9). He has now passed into a public school.

CASE D.—Albert C.[1]; case previously published in detail. Analyses were made on various diets during a time when the stools were coloured and formed. The percentage of fat in the fæces was above the normal (average of four analyses, 27·1 per cent.) and the proportion of soaps high (average 66·7 per cent. of fæcal fat). For the last two years he has kept perfectly well, having grown 6 in. and gained 8½ lb.

(*c*) *Consideration of the Variation in Cœliac Stools.*—Going a step further we gain some information on the matter in hand by considering the variations which occur in cœliac stools from day to day. It is no uncommon thing to be able to note in a case of cœliac disease that the stool one day is pale and unformed, and the next is formed and coloured. This may occur even on a diet containing a constant amount of fat. Indeed, I have several times seen a stool of which the first portion passed is hard and coloured and the latter part pale and "porridgy." For a long time these variations puzzled me, as they cannot well be explained on the supposition that the colour and consistency of the stool depend entirely either on its fat-content or the bile-flow. I have therefore come to think that these variations depend largely upon the distribution of the fats present in the stool; where the proportion of soaps is high the fæces will be coloured, but where the fatty acids are chiefly in excess the characteristic cœliac pallor will be present.

Summary.—My contention that these non-diarrhœic cases are true instances of cœliac disease has been supported by two main lines of argument. First, I have demonstrated that in them, as in the classical type of the disorder, the essential feature is the excessive fat-wastage in the stools. Secondly, I have shown that cases of the classical form of the disease, during their most favourable phases, pass stools which in appearance and on analysis are exactly similar to those passed by the non-diarrhœic cases throughout their course. I therefore conclude that the cases here described are truly cases of cœliac disease in a mild but persistent form.

Diagnosis.

Once it is admitted that cœliac disease in mild form may exist without ever showing diarrhœa or pale stools, the chief difficulty in diagnosis consists in separating such cases from those of general enfeeblement of digestion. It is not easy to lay down any absolute rules in the matter, but if opportunities are given for watching any doubtful case for a while in time the true diagnosis can usually be made. There are suggestive features: 1. The abdomen is enlarged without positive evidence of organic disease; this enlargement varies in individual cases and tends to be at its worst in the evenings, being usually more noticeable when the child is standing than when it is lying down. 2. The appetite is nearly always very poor—there is a very characteristic difficulty in feeding cœliac children; the meals present a domestic problem which at its worst is most distressing. 3. Unexplained pyrexia may be present.

The diagnosis must ultimately turn upon the character of the stool in the presence of these suggestive symptoms. The most constant abnormality of all fatty stools is in their size. They are large for the size of the child and very large for the size of the appetite. A chemical analysis shows that the percentage of fat in them is above the physiological maximum considering the age of the patient and the dietary taken; and this excess of fat is present (in the non-diarrhœic type) without any other grave defect in digestion being noticeable on microscopical examination.

What, then, may we regard as the maximum physiological percentage of fat in the fæces of children? From my own experience I take 20 per cent. as the figure above which the proportion should not go in a child of 3 years or more on an ordinary mixed diet. For children between 2 and 3 years another 5 or perhaps 10 per cent. may be allowed as not abnormal. The diagnosis will be confirmed by watching the effect of treatment. With a reduction in the fat of the diet the child's abdomen will become less prominent, the appetite will usually improve, the patient's temper and spirits will alter for the better, and the stools will become obviously less bulky. Analysis will show that the percentage of fat in the fæces is much reduced but it will remain high for the small amount of fat in the diet.

Treatment.

The treatment of the non-diarrhœic cases follows the same lines as that of the classical type. In principle it consists in ascertaining the optimum intake of fat for the individual case—that is, the amount of fat upon which the child best gains weight and health. Experience teaches me that although there are wide variations between individual cases the best results are obtained when the fæces contain from 20 to 30 per cent. of fat. If the fat in the diet is unduly restricted the child will lose weight, but if too much is allowed the original symptoms will return.

The routine I at present observe is on the following lines:—

1. Analysis of the fæces for fat before altering the diet.
2. Rapid reduction of the fat in the diet to a minimum, hoping to see a reduction of all symptoms and an improvement in the appetite and general condition of the patient; and the ordering of an alkaline mixture of magnesia or rhubarb and soda with the idea

of aiding the saponification of fats in the intestine. In the diet for this stage all milk should be carefully skimmed. This is most thoroughly done by having the milk heated to 200° F. for 20 minutes and then left to stand for four hours. The cream thus clotted is carefully removed. Butter should be replaced by anchovy paste, potted meats, jams, syrup, or honey. Suet and meat fat are not allowed. The child may have eggs, lean meat, chicken, fish, tongue, vegetables, bread, and toast. The chief difficulty is over the puddings: milk pudding made with skimmed milk, boiled rice, sandwich and sponge-cake puddings, stewed fruit, cocoatina, and coloured jellies may be allowed. For drinks, skimmed milk flavoured with tea, cocoatina, or bovril may be given. After two or three weeks of this diet a second analysis is made which gives the minimum practicable percentage of fat in the case.

3. If there is a diminution in the symptoms but at the same time some loss of weight, more fat may be gradually introduced into the diet. The most welcome relaxation is "scrapes" of butter; then the milk may be skimmed more lightly or a little suet may be used in cooking. Each addition should be made separately and, if necessary, controlled by analyses.

4. When the diet seems the most suitable, as judged by freedom of symptoms and gain of weight, I order "kapsols," prepared for me by Messrs. Allen and Hanburys, containing ½ gr. each of sodium glycocholate and taurocholate, prescribing one or two after the three meals of the day to be taken with the alkaline mixture. If, without any alteration in the diet, the percentage of fat in the stools drops or constipation becomes troublesome some more fat may be permitted. I give courses of the bile-salts for alternate months.

5. During the alterations in the diet the child should be weighed every week and its height measured quarterly. It is useful to get the mother or nurse to keep notes on these points.

Characteristics of Fatty Stools.

The various types of fatty stools may be compared and contrasted in tabular form as follows:—

Stool.	Excess of fæcal fat.		
	Neutral fat.	Fatty acids.	Soaps.
Size	Large.	Large.	Large.
Formation ..	Unformed.	Unformed.	Formed.
Consistence ..	Oily.	Greasy.	Soapy.
Appearance ..	Pale.	Pale.	Coloured.
Homogeneity ..	Oil droplets or separated grease.	Homogeneous.	Homogeneous.
Offensiveness ..	Marked.	Marked.	Not marked.
Microscopically	Oil globules.	Masses of crystals.	Coloured flakes of soap.

The stools in all cases of excessive fat-wastage are larger than normal, but apart from their size their other characteristics depend upon the form in which the fat is chiefly passed ("fat-distribution"). Fat may be passed in the fæces mainly as unsplit (neutral, unchanged dietetic) fat, or as split fat (fatty acids and soaps). The characteristics of those containing the two forms of split fat have already been described, and it may be useful to contrast with them the stool containing an excess of neutral fat.

It is generally considered that the proportion of neutral fat in fæces should not exceed 25 per cent. of the total fæcal fat. A greater proportion than this is suggestive of failure on the part of the pancreatic lipase, and the stool indicative of pancreatic insufficiency is often very characteristic. It is very soft and oily and usually abnormally frequent. It is pale, although there is no obstruction to the flow of bile into the intestine. But the most characteristic feature is the occurrence of fat separated out from the fæcal material, either as oily droplets or larger areas of separated fat rapidly congealing on cooling (butterstuhle). To this phenomenon is applied the term of true or pancreatic steatorrhœa. This type of stool is never seen in cœliac disease. Here fat-splitting seems unimpaired. In one case under my care, although the percentage of fat in the stool was as high as 77·2 per cent., only 7·5 per cent. of the fæcal fat was passed unsplit.

On the Pallor of Cœliac Stools.

One of the views advanced to explain the pallor of the stool characteristic of cœliac disease has been that of deficiency of bile excreted into the intestine. Although various writers have issued warnings against the judging of the amount of bile in fatty stools solely by their colour, I do not know that anyone has definitely decided against this theory. In my own mind I have no doubt that bile-pigments pass freely into the intestine, and that the pallor of the stools is due not to their absence but to their being masked by the excess of fat, if present chiefly in the form of fatty acids.

My reasons for this belief are as follows: 1. Colour is quickly restored to the stools if the fat in the diet is rigorously cut down. 2. The appearance of coloured stools in the non-diarrhœic type of cœliac disease. 3. As mentioned above, the remarkable variations in the colour of the fæces from day to day even on a constant diet. 4. I have once seen a case of cœliac disease suffer from an ordinary attack of catarrhal jaundice. 5. It is not really possible to imagine the liver refusing to deal with blood-pigment for months at a time as we should have to do if we are to suppose that no bile-pigment is passed into the intestine. 6. In pancreatic steatorrhœa, although there is no interference with the bile-flow, the stools are pale owing to the masking of the pigment by the excess of fat. This was commented upon by T. J. Walker so long ago as 1889.[3]

On these grounds I therefore conclude that the pallor of the classical cœliac stool does not depend upon an absence of bile-pigment; but this statement must not be taken to imply that the action of the bile on fat absorption is unimpaired. There is no reason why the excretion of bile-pigment and the secretion of bile-salts should necessarily be so bound up together that one cannot be deficient without the other.

Summary and Conclusions.

1. A group of children who fail to thrive owing to their inability to absorb fat properly has been described and the principles of treatment for the condition discussed.

2. It has been shown that in spite of the absence of diarrhœa (in the popular sense of the word), and in spite of the absence of the typical pale, unformed, and stinking cœliac stool, this group is nevertheless cœliac disease in a mild form.

3. It is suggested that the group may be conveniently termed the "non-diarrhœic or dry form of cœliac disease."

4. It has been shown that a stool may contain a large excess of fat (even over 50 per cent.) and yet be formed and coloured if the fat in it is chiefly in the form of soaps; whereas, when chiefly in the form of fatty acids, the excess of fat causes the stool to be pale, unformed, and offensive. The soapy stool is found in the non-diarrhœic group and the fatty-acid stool in the classical diarrhœic form of cœliac disease.

5. Recognition of the non-diarrhœic group suggests that the diarrhœic cases may show considerable naked-eye improvement in the stools without there being a return to the normal power of fat absorption—in other words, that during the quiescent and convalescent stages in cœliac disease the essential failure in fat-absorption will still be recognisable by analysis of the stools. Examples are quoted to prove this point.

6. Its recognition also affords strong evidence against the view that cœliac disease is due to an enteritis or that it has any essential connexion with intestinal disease.[4]

7. A consideration of the two sorts of stool in cœliac disease—the pale fatty acid and the coloured soapy stools—leads to the view that the pallor of the

classical cœliac stool is due not to an absence of bile-pigment, but rather to a masking of the pigment by the excess of fat present as fatty acid crystals.

INJECTION OF ALCOHOL IN THE TREATMENT OF PROLAPSE OF THE RECTUM

IN INFANCY AND CHILDHOOD.

BY LEONARD FINDLAY, M.D., D.SC.,

AND

J. B. DOUGLAS GALBRAITH, M.B., CH.B.

(*From the Medical Department, Royal Hospital for Sick Children, Glasgow.*)

THAT rectal prolapse in infancy and childhood is a troublesome condition to treat no one who has had much experience of out-patient practice at a children's hospital will deny. It is a condition, too, of some seriousness, as it not only causes the patient and his parents much inconvenience, but at times so undermines the general health, especially during infancy, that severe and occasionally fatal complications ensue. These, I have no doubt, are dependent on the accompanying diarrhœa. Though it must be admitted that in a proportion, perhaps even in a majority, of the cases the condition cures spontaneously, this salutary result may be delayed for many months, as the appended table shows, and during this interval much damage to the nutrition of the child may have been caused.

Many devices have been suggested for its cure. These range between simple replacement and strapping of the buttocks and rectopexy or rectococcypexy. Our experience of simple replacement and strapping of the buttocks has been disappointing. We have seen cases treated in this fashion and kept lying prone in bed for weeks without any benefit resulting, in marked contrast to the results of the method described in this paper.

The Method Described.

The method was first seen in practice by one of us (L. F.) in the clinic of Prof. A. D'Espine, of Geneva, and consists in the introduction of a small amount of absolute alcohol into the loose areolar tissue surrounding the rectum. In April, 1921, one of us (L. F.) published a note[1] on the results in some 22 children. Since then we have had a more extended experience of the method, and our first favourable opinions have been fully justified. As the operation is so simple in its technique, so efficient in its results, and apparently so devoid of all danger, we consider that it should be more widely known; hence we are prompted to make this further communication.

The operation must be performed under full anæsthesia, and it is advisable to empty the lower bowel by means of an enema. The prolapse, if down, is reduced and the perineum washed and sterilised with iodine. With the finger in the rectum, to act as a guide, 1·5 c.cm. of absolute alcohol are then introduced on each side into the peri-rectal tissue at a depth of 2 in. to 2½ in. An ordinary exploring syringe is employed, the needle being inserted on each side about ¼ in. from the anal margin. The needle punctures are sealed with collodion, a pad placed in the perineum and kept in position by strapping the buttocks firmly together. Instructions are given that the child must only move the bowels while in the recumbent position, the fæcal matter escaping by the side of the dressing. The pad and strapping are reapplied daily for a week; by this time it has been found, as a rule, quite safe to discard all appliances.

In the cases treated by us there has been no selection. Some of them were exceedingly severe, the prolapse being constantly down, and that to the extent of 4 to 6 inches. Diarrhœa would seem to be no contra-indication. In our opinion the prolapse is more often the cause of the diarrhœa—or at least of persistence of the diarrhœa, probably in consequence of irritation and ulceration of the bowel—than that the diarrhœa is the cause of the prolapse, as is so frequently stated. Should, however, a polypus be present as the exciting cause, it is, of course, necessary that it be removed in the first instance.

Details of Cases.

Details of the cases and results are given in the following table:—

No.	Sex.	Age.	Duration of prolapse.	Date of operation.	Date of last report.	Result of prolapse.
1	F.	10/12	1 m.	5: 5:20	28: 8:22	Returned during whooping-cough. N.R. after 2, 3/12.
2	F.	1, 9/12	19 m.	5: 5:20 11: 9:20	1: 9:22	N.R. after 2 y.
3	F.	5/12	5 d.	7: 8:20	28: 8:22	N.R. in 2 y.
4	F.	3 y.	18 m.	26: 8:20	5: 3:21	Down once with severe straining
5	M.	1, 11/12	1 m.	31: 8:20	29: 1:21	N.R. in 5/12.
6	M.	1, 8/12	2½ m.	20: 9:20	26:10:21	N.R. in 1, 1/12.
7	F.	2, 5/12	3 w.	29: 9:20 2:10:20 20:10:20	26:10:21	N.R. in 1 y. after last injection.
8	F.	4 y.	2 y.	2:10:20	30: 8:22	N.R. in 1, 11/12
9	F.	2 y.	5 m.	6:10:20	2: 8:22	N.R. in 1,10/12.
10	M.	3 y.	1½ y.	16:10:20	31: 8:22	Much improved; still comes down.
11	M.	5½ y.	S.I.	20:10:20	31: 8:22	N.R. in 1,10/12.
12	F.	2½ y.	S.I.	20:10:20	28: 8:22	N.R. in 1,10/12.
13	F.	5/12	1 w.*	26:10:20	27: 8:22	N.R. in 1,10/12.
14	M.	2½ y.	3 m.	27:10:20	4: 9:22	N.R. in 1,10/12.
15	F.	3 y.	1 y.	10:11:20	28: 8:22	N.R. in 1,9/12.
16	F.	3 y.	3 w.	24:11:20	15:12:20	N.R. in 3 w.
17	M.	1, 6/12	2 m.	1:12:20	29: 9:21	N.R. in 10/12.
18	F.	1, 1/12	2 m.	15:12:20	27: 8:22	N.R. in 1, 8/12.
19	M.	3, 1/12	1 y.	15: 1:21		Improved; still comes down occasionally.
20	F.	2, 8/12	2 m.	26: 1:21	12: 3:21	N.R. in 6 w.
21	M.	3, 5/12	1 y.	5: 2:21	28: 8:22	N.R. in 1, 7/12.
22	F.	2½ y.	3 w.	15: 2:21	10: 9:22	N.R. in 1, 7/12.
23	F.	4, 3/12	6 d.	4: 2:21	1: 9:22	N.R. in 1, 7/12.
24	F.	1, 10/12	2 m.	4: 2:21	28:10:21	N.R. in 8/12
25	M.	5 y.	6 m.	23: 2:21 2: 4:21	28: 8:22	N.R. in 1, 5/12.
26	F.	3, 4/12	8 m.	5: 3:21	1: 9:22	N.R. in 1, 6/12.
27	F.	2 y.	14 m.	5: 3:21	29: 8:22	N.R. in 1, 6/12.
28	M.	4 y.	1 y.	12: 3:21	1:11:21	No improvement.
29	F.	3 y.	9 m.	19: 3:21	31: 8:22	N.R. in 1, 5/12.
30	F.	10/52	3 d.	23: 4:21	1: 5:21	N.R. in 8 d.
31	F.	2, 8/12	4 m.	23: 4:21	1: 9:22	N.R. after 1, 4/12.
32	F.	3 y.	2 m.	9: 5:21	1: 9:22	Not down for 7 months (*a*).
33	M.	2, 5/12	6 m.	18: 5:21	4: 6:21	N.R. in 17 days.
34	F.	1, 4/12	3 m.	21: 5:21	3: 9:22	N.R. during past 10/12 (*b*)
35	F.	2 y.	5 m.	1: 8:21	15:10:22	N.R. in 14/12 (*c*)
36	M.	3 y.	3 m.	13: 8:21	15:10:22	
37	F.	2½ y.	4 d.	17: 8:21	28: 8:22	N.R. in 1 year.
38	F.	2, 3/12.	4 m.	4:11:21	1: 9:22	Remained up for 6 m. (*d*).
39	F.	1, 3/12	3 w.	5:11:21	12:11:21	N.R. after 7 days.
40	F.	3 y.	3 m.	5:11:21	30: 8:22	N.R. in 10/12.
41	M.	3 y.	4 m.	9:11:21	1: 9:22	N.R. after 10/12

* Constantly down for 1 week to extent of 3 or 4 inches.
y = years, m = month, w = week, d = day. S.I. = Since infancy.
N.R. = No return.

(*a*) Previously came down a few times during measles and whooping cough.
(*b*) Came down a few times with diarrhœa.
(*c*) No improvement. Child never returned after injection.
(*d*) Then developed measles. Down frequently since.

We have treated 41 children in all. In seven cases the prolapse had been in existence for less than a month; in ten cases it had been present for more than a year. In two cases the operation had to be repeated once, and in one case twice, but in all the other examples only one treatment was necessary to obtain a cure. In 37 (90 per cent.) of the cases a cure was obtained; in 17 of these cases a report was obtained regarding the condition as long as from 18 months to two years after the operation. In two cases the condition was much improved, the prolapse still occasionally coming down. In two cases no improvement was obtained, but in these instances it may be remarked that the operation had only been performed once, the parents refusing further treatment. In no case have we seen any untoward after-effects—in fact, we have been agreeably surprised at the absence of all bladder trouble, which is such a common consequence of any rectal operation.

---

[1] Brit. Jour. Child. Dis., 1921, vol. xviii., p. 83.

It must be admitted that it is somewhat difficult to understand the modus operandi of the treatment. We suggest, however, that the chief factor may be inflammation occurring at the seat of the injection with consequent cicatrisation and anchoring of the bowel, though probably the return of tone to the sphincter ani, which is permitted to take place during the period of strapping, also plays some part.

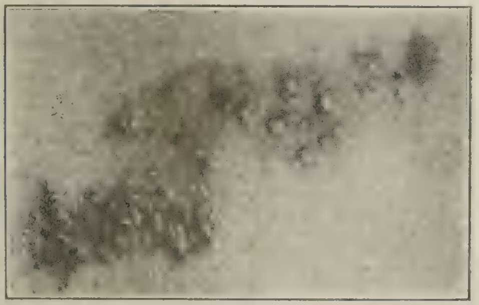
A SKIN ERUPTION DUE TO A MOULD.

By CHARLES RUSS, M.B. LOND., M.R.C.S.

THIS eruption affected a small group of workers employed in sorting and packing various kinds of dried foods—foods, however, which would not be consumed without cooking. The firm was long established, and had no previous experience of a similar occurrence. Some of the workers attended one of the skin hospitals, and presently, in view of the uncommon type of lesion, it was decided to have a bacteriological inquiry made. After infection there appeared on the fourth day a raised red papule, which became vesicular on the sixth and pustular on the eighth day.

I took material from several of the affected workers. In smear preparations few bacteria were visible—viz., a few micrococci and diphtheroid bacilli, and rarely, a spore-like body. Although a number of cultivations were made from several cases there was only a negligible diphtheroid colony obtained from one case. By observation, however, of these apparently sterile cultures a growth occurred after 14 days' incubation of a fine filamentous growth resembling a mould. Microscopic examination of this growth showed a freely branching mycelium bearing endospores. Inoculation of this culture into my arm produced the eruption (Fig. 1). The eruption was highly irritating, and a rather strong burning feeling was experienced at the spreading edges. Dr. Graham Little was interested in the experiment, and successfully prescribed a salicylic ointment to clear up the condition. I recovered the mould in pure culture also from the experimentally produced lesions.

FIG. 1.

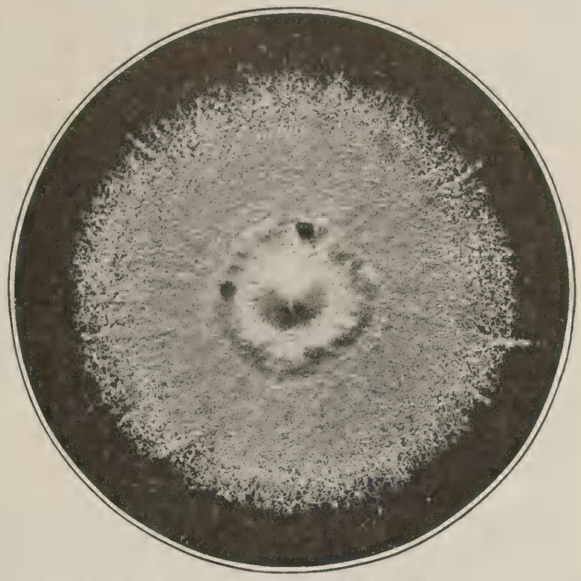


Eruption on forearm. (About natural size.)

A pure culture was submitted to Prof. G. Massee, who reported it to be a typical cercosporella, but one which does not correspond to any described variety. He suggested the apt name for it of *Cercosporella vexans*. It has apparently a resemblance to the asteroid tricophytons.

After the introduction of antiseptic and preventive measures at the works there were no more cases amongst the employees. Before measures were taken no germicides were used in the lavatories, and only one nail-brush had been in common use.

FIG. 2.



The mould after five weeks' growth and before the development of the cotton-wool change in the core.

Location and Character of the Organism.

The next object of the inquiry was to locate the offending organism in the foods or in the sacks in which they arrived from all parts of the Colonies and the Orient. I may mention that the workers were all affected on the palmar surfaces of the forearms only. The work was chiefly done on benches which were usually covered with sacking which had functioned as the container of the goods. There had obviously been inoculation of the workers' skin by friction over the sacking, particularly in the limbs traversing the bench edge. The organism grew well on Sabouraud's medium, which was used for the first 24 hours; after that the cultures were continued at laboratory room temperature.

The characters of the growth were as follows: Second day, a heaped gelatinous mass; fourth day, short silky spines developed on the core; fifth day, a skirting of filaments growing from the edge of the core on the surface of the medium. Eighth to tenth days, three zones are apparent in the growth: (1) the core covered with filaments, (2) dense skirt of filaments, and (3) a halo of filaments at the periphery. Tenth to fourteenth days: (1) the core becomes a snowy growth, (2) this is covered by snowy growth, (3) the peripheral zone consists of long filaments. Fourteenth to eighteenth day, the periphery of the colony cleaves into radially divergent filament groups. Fig. 2 shows the appearance after five weeks' growth. After two months, *duvet* (Sabouraud) change is manifest in the core. The growth is pure white, and after a few months becomes a pale fawn colour.

Extensive cultivations were made from the goods, from the sorted decayed specimens, and from their corresponding sacks, in an attempt to find the source of the organism. I was, however, unable to locate it in any of the numerous samples examined; but the exhaustive search showed, from the number and variety of moulds found and subcultured even from samples under observation for six months, that such a mould might be viable for a long time. In this work I was impressed with its similarity to many other moulds. Several hundred suspected colonies were subcultivated, and further observed on Sabouraud's medium. So close was the resemblance of suspects in the early stages of growth that often it was not until the tenth day that a pale green coloration of the growth signalled the ultimate rejection of a suspect that had copied the pattern for that period.

Microscopy itself I found of little use compared with culture identification. I concluded that the mould was probably contained in some of the sacks, and that there was, of course, direct inoculation by friction into the workers' arms.

Note by E. G. GRAHAM LITTLE, M.D., F.R.C.P. Lond.

My friend Dr. Charles Russ showed me a small patch of a vesicular eruption on his forearm, the nature of which puzzled me considerably. The vesicles were grouped and showed an inflammatory areola, and were accompanied by intense itching. The statement that they had appeared in the site of an experimental inoculation of course removed all difficulty of diagnosis, and the cultures obtained made it certain that the fungus was a ringworm.

Clinical and Laboratory Notes.

A NOTE ON THE TREATMENT OF WHOOPING-COUGH.

BY FRANK PARRY, L.R.C.P. IREL.

THE therapeutic measures in vogue for whooping-cough fall into two categories, the effective but unbearable, and the tolerable but inefficacious. In the first division are antiseptic nasal douches and intramuscular injections of ether. Though these can sometimes abort pertussis, they terrify the little patients, and consequently are so repugnant to their patients that the physician who employs them will find that however beneficial they may be to the sufferer, their effects upon his practice will prove almost lethal. In the second category may be included antispasmodic drugs, of which benzyl benzoate is the best. This symptomatic form of treatment is but palliative, and does not materially shorten the illness or avert its complications. Vaccine therapy is uncertain, being only of use when employed at an early stage, and not invariably then. It is of value chiefly as a prophylactic.

In a recent epidemic I have employed lactic acid bacilli preparations, of which I have found lacteol to be the best. A few grains were blown up the patient's nostrils with an insufflator four times daily. If used more often, slight epistaxis may be caused. This procedure has never been resented by the young or timid. Within 24 hours the puffy appearance disappeared from the face, and vomiting, if present, subsided. The whoop disappeared invariably in a period of from two to eight days. Sometimes a persistent irritating cough at night time has been complained of afterwards. In every instance this was found to be due to a dribbling of mucus from the posterior nares on to the back of the pharynx; it invariably ceased when a sleeping posture was adopted that caused the floor of the nasal fossæ to incline forwards.

The first experiment was made on the hypothesis that *B. acid lactici* might overwhelm *B. bordet*, but this explanation of the action of this remedy can hardly be accepted, the improvement in the symptoms taking place so quickly. Possibly the effect is in the nature of a protein reaction. My series of cases (30) is small, but the results were so marked and so uniform that I feel justified in calling without more delay for the verdict of others better equipped for making observations and with ampler clinical material than myself, on this simple, unobjectionable, and, in my experience, speedily effectual method.

Birmingham.

THE CHRONIC ANTRUM.

BY T. B. JOBSON, M.D., B.CH. DUB.,

EAR, NOSE, AND THROAT SURGEON, ROYAL SURREY COUNTY HOSPITAL, GUILDFORD; REGISTRAR, CENTRAL LONDON THROAT HOSPITAL.

THERE appeared in THE LANCET of Nov. 18th last an article by me on The Acute Antrum, in which I pointed out that nasal sinus suppuration is much commoner than is generally recognised, that it is responsible for many of the toxæmias which are labelled neuritis, rheumatism, nasal catarrh, dyspepsia, &c., and that the signs indicating the septic focus in the sinus may be slight or altogether absent. I urged the importance of bearing in mind the possibility of sinus infection in obscure cases where a cause for toxæmia—either acute or chronic—could not be found.

On Nov. 19th a lady came to consult me; she gave a history of neuritis and had had a slight post-nasal discharge. I inquired the name of the doctor who had referred her to me. "No doctor," she replied, "I read your article in THE LANCET and formed the opinion that I might have an 'antrum.'" "You are a doctor, I presume?" "Oh no, I just take an interest in medical matters—and so I read THE LANCET."

I examined her nose. There was no sign of pus visible by anterior and post-anterior rhinoscopy. The mucous membrane of the nose looked pink and healthy. Transillumination showed the shadows equal and fairly clear on both sides. I informed my patient that so far I had found no evidence of sinus infection, but to make certain I should have to puncture the antrum and wash it out. She was eager to have this done. After cocaining the left side I washed out from the antrum through a Lichtwitz cannula several blobs of muco-pus.

This was rather a wonderful diagnosis for a laywoman. In her the medical profession missed a keen diagnostician! The story goes to prove that nasal sinus suppuration is unobtrusive and that if the possibility of its presence is not borne in mind, and unless it is carefully searched for, it will escape detection, much to the detriment of the patient.

HEMILARYNGECTOMY FOR CARCINOMA.

BY FRANCIS MUECKE, C.B.E., F.R.C.S. ENG.,

ASSISTANT SURGEON, EAR, NOSE, AND THROAT DEPARTMENT, LONDON HOSPITAL.

THE following unusual case illustrates the value of hemilaryngectomy for carcinoma:—

The patient was a thin, frail woman aged 48, who had suffered from two months' hoarseness. Examination showed definite growth of the anterior half of right vocal cord, about the size of a haricot bean, and slightly encroaching on subjacent tissue. There was slight movement of the right arytenoid only. With the bronchoscope a small piece was removed for examination and found to be epitheliomatous.

After a preliminary tracheotomy, a window was removed from the right wing of the thyroid cartilage (after Lack), leaving only a thin rim with the muscle attachments undisturbed. With the window all the subjacent tissue were removed. The vessels were easily ligatured coming from under the external rim, and an excellent view of the left side of the larynx obtained. The growth was seen to be well included on the inside of the removed window. The thyroid and hyoid muscles were then sewn over the opening and the wound closed. The tracheotomy tube was left in five days and the patient was discharged on the eighteenth day with a fairly audible voice.

Seen six months later, the patient had increased in weight and was stated to be in excellent health. The voice was good, well above an audible whisper, and could be understood across the room. The muscles had protruded slightly into the larynx, and a distinct ridge was seen where the left cord impinged. There was no sign of any growth or ulceration.

One of the benefits claimed for this method is that the operation can be speedily performed and so greatly assist in the prevention of broncho-pneumonia so favoured by long anæsthesia. The total time of the above operation was 25 minutes. Furthermore, subsequent movements of the larynx are little interfered with and the mucus therefore easily dislodged and expectorated, and not allowed to lie about and become septic. The patient should be made to sit up immediately following recovery from anæsthesia.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY.

A meeting of this section of the Royal Society of Medicine was held on Jan. 3rd, with Mr. James Berry, the President, in the chair.

Mr. W. Sampson Handley opened a discussion on

The Pathology and Operative Treatment of Renal Calculi.

He said that it was commonly held that renal calculi were formed only in the pelvis or calyces, but his own observations in two cases suggested that a stone might originate in a cyst in the substance of the kidney unconnected with a calyx. In the first of these cases calculi were removed from one kidney successfully, but death occurred after the removal later of a number of stones from the other kidney. The necropsy showed a small cyst in the second kidney containing turbid fluid and lined by gritty débris. The cyst was not connected with the calyces. The second observation occurred during an operation; a number of calculi were removed by subcapsular pyelotomy, but two small calculi known to be present could not be detected by a finger within the pelvis. Bi-digital palpation revealed slight induration at two points, and on incising the kidney at these points the calculi were found, each lying in a smooth-walled cyst unconnected with a calyx. A specimen (No. 3618) in the museum of the Royal College of Surgeons of England showed a calculus in the renal pelvis, while there was an empty cystic cavity close to the capsule communicating by a narrow neck with a long dilated calyx. He suggested that the stone had formed in the cyst and ulcerated into the calyx, from which it passed to the pelvis. Again, kidneys which were the seat of calculi were often described as having calyces extending almost to the surface, although the kidney substance was not greatly atrophied, while normal calyces ended at the apices of the pyramids. He was unable to form any estimate of the frequency with which stones were formed thus, but he suspected that it was not uncommon. It was evident that the conditions within a urinary cyst of the kidney favoured precipitation.

Pyelo-lithotomy v. *Nephro-lithotomy.*

Mr. Handley considered the splitting of the kidney to be a procedure only to be adopted as a last resort, since it sometimes caused dangerous bleeding and always caused permanent injury to the secreting substance of the kidney. Nephro-lithotomy was, however, the only possible procedure short of nephrectomy in some cases, such as very large stone, or in cases with a short pedicle and a deep loin. Restricted nephro-lithotomy—i.e., the extraction of stones through small incisions in the kidney—was advocated by Hartmann when a stone could be plainly felt in the kidney near its surface. This had the merit of rapidity, directness, and simplicity. During the operation the kidney pedicle should be compressed by an assistant, and the incisions should be closed by catgut sutures. Bipolar nephrotomy (Legueu) was advocated by some surgeons when the stone could not be palpated externally. In this operation the kidney pelvis was reached by incisions in the upper and lower thirds of the kidney-splitting incision into the upper and lower calyces. It was claimed that the whole kidney could be explored thus, but the speaker had found it useless for exploring the pelvis. Albarran's "Unipolar nephrotomy" was open to the same objection. The plumber seeking a defect in a drainage system opens first the manhole into which the accessory drains converge, and from which all are accessible. For similar reasons Mr. Handley maintained that the kidney should be explored from the pelvis in all cases with the limited exceptions already made. Pyelotomy should be the routine first step in the operative examination of the kidney, and nephro-lithotomy regarded as a last resort.

Pyelotomy.

Pyelotomy was an operation of comparatively recent introduction; it was not mentioned in the 1904 edition of Cheyne and Burghard's Manual of Surgical Treatment. The operation consisted of the opening of the renal pelvis by a longitudinal incision in its posterior aspect after delivering the kidney and clearing the fat from the pelvis. A posterior branch of the renal artery and irregular vessels should be avoided. Through this incision a stone in the pelvis could be extracted and the interior of the pelvis and calyces explored by means of a probe—a stone so discovered being extracted with forceps. The wound in the pelvis could be closed by interrupted catgut sutures or, as Thomson Walker advocated, by suturing over it a flap of fibrous capsule turned down from the kidney. Mayo originally used a flap of fatty tissue for a similar purpose, but had now, according to Hartmann, given up any form of suture as unnecessary. While there could be no doubt that suture of the pelvis was unnecessary and tedious, and might reduce the size of the pelvis, the speaker considered that the accurate closure of the wound was desirable if it could be simply and quickly done. In order to attain this he had devised and practised the operation of

Subcapsular Pyelotomy.

The kidney, with its capsule intact, having been delivered from the lumbar wound, an incision three inches in length was made in the fibrous capsule on the posterior surface of the kidney parallel to its convex margin. The capsule was then stripped off the kidney in the direction of the pelvis until the hilum of the kidney was reached. The pocket thus formed was enlarged by blunt dissection until the line of entrance of the pelvis to the kidney was reached; the pelvis was then incised in the line of the long axis of the kidney. Forceps, or the finger if necessary, could now be inserted into the pelvis, its interior explored, and any stones removed. The opening in the pelvis could then be rapidly and effectively sealed by three catgut stitches in the original incision in the capsule. This method of approach had the merit of simplicity, and the flap tended to prevent the soiling of the peri-renal tissues in septic cases. The security from a urinary fistula was apparently absolute. Mr. Handley had performed this operation about a dozen times without any complications. He did not carry his incision in the pelvis too high for there was a theoretical risk of wounding a posterior branch of the renal artery, although he had not had any trouble from this source. Cases of compound branching pelvis did not present the difficulty they might theoretically be expected to do, for the branching did not occur until the pelvis had entered the renal sinus, so that an incision made as described would generally open the main renal pelvis.

Bi-digital Exploration of the Kidney.

When a calculus, known to exist, could not be detected by a probe the incision in the pelvis should be cautiously enlarged until it would permit the introduction of the gloved forefinger; it was then possible by palpation between an external finger and the finger within the pelvis to detect even stones lying in cysts within the renal substance. When a stone had been detected in a calyx thus, it was probably safer to remove it through a small incision in the renal substance, keeping the finger in the pelvis as a guide, than to attempt its extraction through the pelvis and a probably constricted calyx. Mr. Handley urged this method of exploration in preference to nephrotomy, and claimed that while it did less damage it provided a more certain method of discovering a stone than the complete splitting of the kidney. The increased danger of urinary fistula, said by some authorities to follow pyelotomy, was obviated by employing the subcapsular method of approach.

Discussion.

Mr. Frank Kidd agreed that splitting the kidney was a dangerous procedure, and stated that the bimanual method of exploration had been employed by urinary surgeons for several years, and stones extracted by limited nephrotomy. He did not like the idea of subcapsular pyelotomy, however, as there was often a large artery low in the pelvis which ran a risk of being wounded by a transverse incision; he thought it safer to perform pyelotomy by an incision in the long axis of the renal pelvis. He had not seen fistula occur after pyelotomy in over a hundred cases; when it did occur it was due to fragments of stone being missed and blocking the ureter. Attempts made to ensure the complete removal of stones by the use of a portable X ray apparatus in the operating theatre had not been very successful in the past, but the Mayos had now an efficient plant for this purpose, although it was still highly dangerous. For bilateral cases he preferred to operate on both sides at one sitting.

Prof. F. HOBDAY said that stone in the kidney or bladder was not uncommon in certain animals, such as the horse and dog, while it was rare in the sheep, pig, and cow, which had shorter lives. In veterinary practice nephrectomy was the only operation employed; he intended to give subcapsular pyelotomy a trial.

Mr. SWIFT JOLY thought it inadvisable to decide on any type of operation beforehand, but chose the operation which best suited the conditions disclosed when the kidney was exposed. In a fat patient pyelotomy was often difficult, but it was to be preferred when possible. Large size was not a contra-indication to pyelotomy when the stone was in the pelvis, and even a branched stone could be removed if naturally divided into two parts and faceted. A large branched single calculus was best removed by nephrotomy and the same operation was necessary for stones in strictured calyces, although calyx stones might readily be removed through the pelvis when there was no stricture. It was becoming unusual not to be able to locate a stone, but when this occurred he opened the pelvis and explored the calyces with the little finger; if this failed he opened the lower calyx from the kidney. He believed that all stones had their origin in a calyx and the cysts described by Mr. Handley were merely parts of calyces which had been shut off; this was known to occur in tubercle.

Mr. HAROLD WILSON emphasised the danger of secondary hæmorrhage after nephrotomy; it had occurred four times in his own practice and he had seen four cases after this operation performed by other surgeons. When this happened nephrectomy was the only recourse. Limited nephrotomy was less dangerous, and he had once been able to wash 60 small stones out of a calyx after incising it from the kidney. He closed an incision in the kidney by two layers of catgut sutures in order to minimise the risk.

Mr. R. H. JOCELYN SWAN said he had reported a case where a stone was found at operation to have been formed in the kidney substance, in which it was firmly gripped. He agreed that it was better to decide on the type of operation when the kidney was exposed, although his preference was for pyelotomy on account of the danger of hæmorrhage after nephrotomy. When he could not feel the stone he opened the pelvis by a longitudinal incision and proceeded to the bi-digital exploration and limited nephrotomy described by Mr. Handley. He made no attempt to suture the pelvic wound accurately and thought there would be no risk in leaving it completely open. No urinary fistula had occurred after pyelotomy in his practice.

Mr. J. E. ADAMS also preferred pyelotomy, but employed a transverse incision in the pelvis when the stone was large. Fistula when it occurred was due to portions of a stone left behind, or to sepsis.

Reply.

Mr. HANDLEY, in reply, said that he believed the branch of the renal artery referred to by Mr. Kidd was pushed aside in stripping the capsule in his operation, since he had not encountered serious hæmorrhage in any case. The case of bilateral stone which he had described was too ill to have stood a bilateral operation. The subcapsular operation was easier to perform than direct pyelotomy when the kidney could not be delivered completely. For hæmorrhage from the kidney he had found plugging with vaselined gauze more effective than suture in one case.

LIVERPOOL MEDICAL INSTITUTION.

A MEETING of this Society was held on Dec. 21st, 1922, with Dr. C. THURSTAN HOLLAND in the chair.

Dr. OSCAR DE JONG read a note on the

Ætiology of Dermatitis in Bakers.

He said that baker's dermatitis occurred in bakers employed in bakeries where the hands are used in mixing, not in bakeries where machines are used. Investigations showed that the flour used was not responsible, as no cases of dermatitis were found in men employed in flour-mills, though these were constantly handling flour. Similarly, no cases were found in men handling or preparing yeast. Dr. de Jong said that the condition was due to immersing hands and arms in the salt solution which is added to the flour, which is about 3·6 per cent. in strength. Owing to the temperature of the bakehouse and the ovens the salt crystallised on the arms of the workman, and the process of kneading worked the crystals into the skin, setting up a dermatitis in susceptible individuals. Cure was obtained by rest from work and local treatment. Dr. de Jong suggested prophylaxis by the use of a spray of fresh water after mixing the salt solution and at periods during kneading. The condition relapsed as a rule, on return to work.

Dr. FRANK H. BARENDT alluded to the terminology of this affection and showed that it was well known in bygone ages. He emphasised the fact that the proportion of those suffering from baker's itch was but slight. In spite of the number of possible excitants and a too vigorous use of soap and water in ablution this circumstance should not be overlooked; one was compelled to admit the presence of idiosyncrasy. Nevertheless, all the necessary preventive measures to which Dr. de Jong had drawn attention should be taken.

Dr. DOBBIN CRAWFORD read a paper on

Clean Milk.

She said that America was the pioneer of the clean milk movement. In England the National Clean Milk Society was founded in 1915, with the following objects: (*a*) To examine the condition of milk as received by the consumer; (*b*) to furnish a standard of clean milk; (*c*) to create a demand for clean milk. It was found in 1915 that the average sample of London milk contained more than 3,000,000 bacteria per c.cm. Tubercle bacilli were present in 10 per cent. of the samples and over 99 per cent. contained *Bacillus coli*—absolute evidence of contamination with manure. A standard of clean milk was furnished in the licences issued by the Ministry of Health in 1921 for the production of Certified Grade A milk, which must contain no *B. tuberculosis*, no *B. coli*, and not more than 30,000 bacteria per c.cm. at any time before reaching the consumer. It must be delivered within two days after the day of production, and every animal in the herd must be examined by a veterinary surgeon and give a negative reaction to the tuberculin test at intervals of three months. Dr. Crawford proceeded to give the following statistics of Liverpool milk, which were quoted from the report of the public health department: Of 943 samples examined in 1921 from 9 to 15·6 per cent. contained tubercle bacilli. The veterinary inspectors in 1921 found 31 cows with tuberculosis of the udder supplying milk to the city. From 80 to 90 per cent. of the samples tested contained *Bacillus coli*, and in that year diarrhœa and enteritis killed 683 infants in Liverpool.

Dr. Crawford considered that the practical effect of grading milk was rapidly to raise the standard of the whole milk-supply, it tended also to increase the consumption of milk. The cost of certified milk was

7½*d*. a pint, just double that of ordinary milk. The need of the moment was the education of the consumers so as to increase the demand for clean milk. Dr. Dobbin Crawford showed a number of lantern-slides to illustrate clean methods of production and their effect. These were taken at the Storms Farm Dairy, Keswick, from which she had received certified milk during the present year. The reports of this milk by the Ministry of Health showed that when 17–18 hours' old it contained no *Bacillus coli* and an average of only 242 bacteria per c.cm. She had persuaded a dairyman in Wallasey to retail this milk, but owing to lack of demand it was not procurable in Liverpool.

Mr. W. A. Thompson read a paper on the

Acute Abdomen in the Child Based on 100 Consecutive Cases.

These included 53 cases of acute appendicitis, 15 of which had general peritonitis; of these 5 died. There were 27 intussusceptions, the great majority occurring between the fourth and eighth months, 21 recovered, 6 died, 3 following resection and lateral anastomosis, one of which lived 19 days, and one case moribund on admission died soon after reduction had been performed. The reduction should be intra-abdominal. Many cases were associated with enlarged ileo-cæcal glands, some of which were connected by bands to the gut immediately in front of the original apex of the intussusception. Mr. Thompson explained how these might cause an intussusception and how a much enlarged gland caused a recurrent incipient intussusception. The majority of cases commenced as ileo-ileal—66 per cent.; 8 cases of acute intestinal obstruction were operated on, 5 of these recovered. Three cases of strangulated herniæ had been met with in over 1000 of Mr. Thompson's cases; they all recovered. In pyloric stenosis a plea was put forward for nepenthe ♏ $\frac{1}{6}$ to ♏ $\frac{1}{3}$ doses, and in the severe progressive type an early Ramstedt operation, to which Mr. Thompson attributed his absence of mortality. Cases of volvulus, pneumococcal peritonitis, and hernia of the umbilical cord were also described.

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

A MEETING of this Society was held in the Department of Pathology, University of Sheffield, on Jan. 5th and 6th, with Prof. J. S. C. Douglas in the chair.

S. McDonald (Newcastle) showed a remarkable spinal deformity in a small trout he had caught in a Highland loch in which the vertebral column was curved laterally and dorsi-ventrally. Similar deformities were known in other fish. Histologically there was some resemblance to human achondroplasia.

F. W. Simson (Sheffield) described a case of splenectomy for splenic anæmia in which the spleen showed nodules of fibrosis with giant cells but with no discoverable tubercle bacilli similar to those published by A. Stengel, E. H. Kettle, and others. There was also a lupoid condition of the skin which was also negative for tubercle microscopically and by inoculation.

A. F. B. Shaw (Newcastle) discussed an example of primary growth of the liver (hepatoma) showing marked nuclear vacuolation and degeneration, active bile formation, and local malignancy by the invasion of blood-vessels. He described also a solitary myeloma of the humerus composed of plasma cells; the patient showed no Bence-Jones albuminuria and was successfully treated by local excision.

M. J. Stewart and H. H. Gleave (Leeds) reviewed the Leeds experience of the relation between cirrhosis and carcinoma of the liver. In 166 post-mortems showing cirrhosis there were six examples of carcinoma and three among 3600 without cirrhosis; of six cases of cirrhosis with hæmatomachrosis two had carcinoma. Allowing for sex and age, carcinoma is at least 25 times more common in cases of cirrhosis than in those without.

H. A. Haig (Cardiff) directed attention to certain granules found in the cells of malignant tumours during mitosis which by their staining reactions he judged to be of nucleolar origin.

J. Davidson (Edinburgh) had found that the repeated application of tar to the skin in rabbits produced marked changes in the liver, first necrosis and degeneration without fatty change and later nodules of regeneration with irregular cirrhosis. The lesions have no definite lobular localisation.

A. Leitch (London) discussed some points in the surgical pathology of cancer of the rectum with special reference to the permeation of lymphatics.

M. B. R. Swann (Cambridge) described the functional effects of X rays; the most marked result was a fall of blood pressure when the whole animal was radiated which might progress to a fatal issue; isolated heart, uterus, and intestine were stimulated and the heart ultimately killed in systole.

J. H. Dible and P. C. Gibson (Manchester) had found that injections of Pfeiffer's bacillus or its toxin produced the preliminary leucopenia followed by a neutrophile leucocytosis (with a curious increase in nucleated red cells) which is caused by many other organisms.

W. J. Wilson (Belfast) described media suitable for the study of the sulphur bacteria and for investigating the reduction of sulphites by many of the well-known pathogenic organisms.

J. W. McLeod, J. Gordon, and L. N. Pyrah (Leeds), in continuation of their work on the production of hydrogen peroxide by pneumococci, had found that *B. acidophilus*, *B. bulgaricus*, and other lactic acid species also produced peroxide which could conveniently be demonstrated by a benzidine-chocolate (Crowe-Penfold) medium.

J. W. McLeod (Leeds) described a fatal human case of multiple abscesses in liver and lung from which by blood culture during life he had isolated a streptococcoid yeast-like organism (blastomyces ?), pathogenic to rabbits but not to mice or guinea-pigs.

S. L. Cummins and C. M. Acland (Cardiff) brought forward the results of an extensive study of tuberculo-opsonins. Taking as an index the percentage of active phagocytes, rather than the number of bacilli taken up or the dilution of serum at which phagocytosis ceases, they drew particular attention to the occurrence of "zones of inhibition" which are shown only if various dilutions of serum are examined at each trial.

A. Gough (Leeds) described yet another method of doing the Wassermann reaction with human complement.

A. F. Watson and U. Wallace (Beckenham) showed that it was possible to produce large quantities of uniform high-grade diphtheria toxin by careful attention to the preparation of P. Hartley's modification of S. R. Douglas's horse-flesh peptic digest medium.

J. C. G. Ledingham (London) showed specimens illustrating the histology and diagnosis of tularæmia infection in animals and man.

H. H. Gleave (Leeds) demonstrated a case of multiple gastric adenomatous polypi coexisting with a carcinoma.

J. G. Greenfield (London) described the histology of the changes in the muscles in two cases of Volkmann's contracture and discussed the causation of the muscle atrophy and degeneration and the consecutive fibrosis from the periphery.

G. S. Williamson (London) exhibited a number of microscopical preparations showing what he believed to be an undescribed system of intercellular tubules in the thyroid and other secreting epithelia.

G. Wilkinson (Sheffield) demonstrated his model of the cochlea.

Mrs. May Mellanby (Sheffield) exhibited a large number of specimens illustrating her work on the effects of diet on the growth of teeth, and discussed the significance of the results which had been obtained.

Many pathological specimens of interest were shown by Prof. Douglas and the staff of the department.

Reviews and Notices of Books.

The Practice of Medicine.

By A. A. Stevens, A.M., M.D., Professor of Applied Therapeutics in the University of Pennsylvania, Philadelphia; Visiting Physician to Philadelphia General Hospital. London and Philadelphia: W. B. Saunders Company. 1922. Pp. 1106. 35*s.*

This new text-book of medicine comes as a proof that physicians are still prepared to face the task of giving a personal survey of the whole of their vast subject. Recent years have seen the appearance of several new text-books and new editions of well-known ones, a striking change in each case being the allotment of various sections to different writers. Dr. Stevens has courageously followed in the footsteps of his old master, Sir William Osler, and of other famous writers, and has produced his book almost unaided. We congratulate him on the result, and if it be said that his work shows no great advance over similar existing volumes, it is nevertheless true that the views of one master, expressed by himself, make an appeal to certain types of student stronger than the varying voices of a series of experts. An inherent disadvantage, however, of the one man-power book is that certain subjects must be less well treated than others, and we regret the stress which Dr. Stevens at times lays on aspects of pathology which are at present without the full support of considered criticism. Thus his chapter on asthma appears to pay too much attention to the chemical side of the disorder and deals very briefly indeed with the nervous factors. Rickets is placed in a section devoted to food-deficiency diseases, though the evidence adduced in favour of such classification is hardly convincing; the work of E. Mellanby is not even referred to. If in some directions Dr. Stevens appears hasty in his acceptance of new pathological conceptions, there are others in which he is more conservative than are most of the modern British writers. Thus he places diabetes mellitus amongst the disorders of metabolism and shows some reticence in accepting the pancreas as the chief seat of disease; there is no reference to the recent work on insulin. In the section on nervous diseases the description of subacute combined degeneration is somewhat inadequate, and the inaccurate term "sclerosis" is employed in describing the pathological changes in the cord.

Such inequalities as we have pointed out are an indirect tribute to the rarity of serious defects in a volume which will take a worthy place amongst the accepted text-books of medicine.

Diathermie et Diathermothérapie.

By Dr. H. Bordier, Professeur agrégé à la Faculté de Médecine de Lyon. Preface by Prof. Bergonié. Paris: Baillière et Fils. 1922. With 137 illustrations. Pp. 512. Fr.30.

This large book contains seven parts, of which the first deals with the physics of high-frequency currents and the principles underlying the production of currents of sustained oscillation capable of producing diathermy. Various types of apparatus are described in the second part, which treats of the conduction of high-frequency currents by the body, the path which they take through different conductors, and the resistance offered to them by the body. The third part deals with the physical and physiological properties of the diathermy current. Various experiments are described in order to show the rise of temperature which these currents can cause in inert conductors, excised tissue, and the living body. Some experiments on animals are included, and the influence of diathermy on the respiratory and circulatory systems is discussed. The properties of diathermy as a cauterising agent, and the ways in which they differ from those of other methods, are described in the fourth part, together with various electrodes and the ways in which the operation of cauterisation by diathermy can be performed. The different morbid conditions which can be treated with advantage by surgical diathermy are next considered, while medical diathermy forms the subject of the sixth and seventh parts, the former dealing with technique, the latter with clinical experience in the use of diathermy for the treatment of diseases of the various systems of the body.

Prof. Bordier's book is as far as we know the first book published by a French author on the principles and practice of diathermy, and English practitioners of electro-therapeutics will find much that will interest them and confirm in their minds the value of diathermy in the treatment of many maladies, and the good results obtained in the treatment of diseases such as rhinophyma, lupus erythematosus, lupus vulgaris, xanthelasma—these being conditions for which it has been used less often in this country. Of special interest is the account of the effects of diathermy applied to the abdomen for dilatation of the stomach with diminution of the hydrochloric acid; the dilatation was reduced and the quantity of acid increased, as was ascertained by means of test-meals. The author states that the use of diathermy for the destruction of malignant growths has received less attention in France than in England, and he gives full recognition to the work of English electrologists. He indicates the value of diathermy for the removal, without hæmorrhage, of enlarged tonsils. He also points out the usefulness of diathermy for the destruction of enlarged prostate, and quotes some brilliant results obtained by Luys. The operation, he says, can be performed without general anæsthesia and on out-patients, but interference must be restricted to cases in which the enlarged gland does not extend into the bladder. Altogether Prof. Bordier's work is a comprehensive yet concise treatise on its subject.

Anæsthetics.

Practical Anæsthetics. By Charles F. Hadfield, M.B.E., M.D. London: Baillière, Tindall and Cox. 1923. Pp. 244. 7*s.* 6*d.*

This is a small book, easy and pleasant to read, and gives in clear terms most of the important facts about the selection and use of general anæsthetics. Dr. Hadfield has wisely not confused his issues by a multitude of alternatives, but has generally selected what he considers the best methods, has described their use fully and plainly, and has ignored the rest. Thus he furnishes the inexperienced with a useful guide to practice. With one or two observations we do not agree. Laryngeal spasm we believe, contrary to the author's statement, to be more frequent during chloroform than during ether anæsthesia, and we do not think that the commonly used doses of atropine affect the pupil at all. In explaining post-anæsthetic lung complications, Dr. Hadfield ignores massive collapse and reflex inhibition of the diaphragm. For routine use he favours induction by means of ethyl chloride and ether with 1 in 16 of chloroform. This is used in a Clover's inhaler. It is undoubtedly a very effective and rapid method which is not unpleasant to the majority of patients. For abdominal cases open administration of ether is preferred by Dr. Hadfield.

This little book will be found useful by practitioners and students.

Anæsthesia in Children. By C. Langton Hewer, M.B., B.S., Assistant Anæsthetist to St. Bartholomew's Hospital. London: H. K. Lewis and Co. With 31 illustrations. 1923. Pp. 111. 4*s.* 6*d.*

Dr. Hewer is right in claiming that too little importance is usually attached to the giving of anæsthetics to children, and that the average medical student leaves a general hospital having little knowledge and less practical experience of that particular use of anæsthetics. Yet it is true that young children exhibit peculiarities in their reaction towards anæsthetics that are important to recognise and that can be learned only by experience. The practitioner almost inevitably is called on to give anæsthetics sooner or later to a young child. The brief operations commonly performed on the young are often thought to be just those the anæsthetic for which may safely be trusted to one not necessarily an expert in administration. Actually the opposite is the truth, and the disastrous result of not realising it may be read in the returns of the Registrar-General. Quite a formidable position will be found there occupied, for instance, by fatalities during the operation of circumcision, and we regret that Dr. Hewer does not single this common little operation out for special mention. His book gives much sensible advice, both as regards actual administration of the anæsthetic and on preparation and after-treatment. We hope, however, that his use of the verb "induce" as applied to the patient instead of to the state of anæsthesia will not become common; the patient "was induced with closed ethyl chloride" is not a happy phrase, provoking the question what closed ethyl chloride and the patient were together induced to do. Dr. Hewer's statement of the general principles to be observed in managing children is sound, and the little book is distinguished by a conciseness valuable to young practitioners. It should be a welcome addition to the library of residents at children's hospitals.

DICTIONARY OF MEDICAL TREATMENT AND DIET.

Second edition. By JAMES BURNET, M.D., Lecturer in Diseases of Children, School of Medicine of the Royal Colleges, Edinburgh. London: A. and C. Black, Ltd. 1922. Pp. 156. 5*s*.

A subtitle, "A Guide to Therapeutics for Students and Practitioners," describes well a book which contains something more than the treatment which can be derived from text-books of medicine, but much less than the large indexes of treatment from which it differs in being purely medical. It is a handy volume for quick reference on ordinary medical subjects. The author steers successfully between the difficulty of treatment without sufficient diagnoses—that is, of treating symptoms and not diseases—and that of filling too large a portion of his book with notes on differential diagnosis. It is perhaps from conviction, but perhaps from oversight, that he dismisses modern treatment of syphilis very lightly in saying, "Intravenous injections of kharsivan, neo-kharsivan, or galyl may be given in suitable cases. These injections are a valuable adjunct to the ordinary medicinal treatment." Again, X ray treatment of ringworm is dealt with in the sentence, "The most rapid and satisfactory results, however, are obtained by the use of Rontgen rays," and a warning against the use of these rays by the novice. Even if the student or practitioner does not want to use these methods he wants to know more about the technique than these brief sentences convey. The appendix on diet is short but not inadequate.

LES PHÉNOMÈNES DE DESTRUCTION CELLULAIRE.

By LOUIS BORY. Paris: Masson et Cie. 1922. Pp. 211. Fr.12.

Dr. Bory has put together a well-arranged and readable account of autolysis, cytolysis, bacteriolysis, and kindred phenomena. The information he gives is already easily available in other places, and he does not deal with it in any particularly original way; however, though the book may not throw fresh light on the subjects it deals with, it can nevertheless be read with pleasure and profit. Among a great mass of good material, we must note two topics which are badly dealt with. The account of isohæmolysins (pp. 174 ff.) fails to appreciate at all the significance of "blood-groups," either from the point of view of genetics or that of practical transfusion. In the section on the poisonousness of the products of autolysis (pp. 32 ff.), those who are familiar with the work on secondary shock, no longer very new, will be surprised to find no reference at all to Cannon, Bayliss, and Dale. It has surely been one of the greatest pieces of recent progress in general pathology to realise that the remnants of destroyed cells, which can, in small amounts, arouse the reaction which results in the healing of the wound which caused the destruction, will in increasing concentrations produce more and more substantial evidence of general poisoning until in very large amounts they are pretty rapidly fatal. Dr. Bory's book is beautifully produced.

THE THEORY OF EMULSIONS AND EMULSIFICATION.

By WILLIAM CLAYTON, D.Sc., F.I.C., Secretary to the British Association Committee on Colloid Chemistry and its General and Industrial Applications. With Foreword by Prof. F. G. DONNAN, C.B.E., M.A., Ph.D., D.Sc., F.R.S. London: J. and A. Churchill. 1923. With 22 illustrations. Pp. 160. 9*s*. 6*d*.

THE study of emulsions forms one of the most important and interesting in the domain of physical chemistry; emulsions are of great theoretical interest in connexion with the properties of emulsoid colloids, in relation to the problems of surface-tension, adsorption and Brownian movement, and furthermore, have many points of contact with biochemistry. One of the most interesting of these is the question of the inversion of emulsions, or reversal of phase, in its relation to the permeability of membranes. These properties will be found fully discussed in the present volume, which also contains much that is of importance to the technical chemist—for colloid chemistry has many applications to industry. This monograph, though representing a special branch of the special subdivision of physical chemistry known as colloid chemistry, will find a ready place in our literature, and will be acceptable to a wide circle of specialists, as well as to students of physical chemistry.

A LABORATORY HANDBOOK OF BIOCHEMISTRY.

By P. C. RAIMENT, B.A. Oxon., M.R.C.S., L.R.C.P., Senior Demonstrator of Biochemistry, University of Oxford; and G. L. PESKETT, B.A. Oxon., Demonstrator of Biochemistry, University of Oxford. London: Edward Arnold and Co. 1922. Pp. 102. 5*s*.

THIS little book is intended for the junior student. Throughout short theoretical accounts precede the practical work on the same subject. The authors appear to have carried the process of elimination, even for a junior student, a little far, for among the tests or exercises omitted are Seliwanow's test for cane sugar, Volhard's method of estimating the chlorides in urine, and the acetone method for the extraction of urea from urine. There is an error on p. 43 where cholesterin is included with lecithin as a phospholipin; it is correctly described on the next page.

DIE EPIDEMISCHE ENCEPHALITIS.

By Prof. Dr. Med. FELIX STERN, Oberarzt der Universitätsklinik für Psychische und Nervenkrankheiten, Göttingen. Berlin: Julius Springer. 1922. Pp. 228.

THIS is a monograph treating of certain features of epidemic encephalitis which have specially interested the author. It does not pretend to give a complete account of the disease. Prof. Stern has based his monograph on 105 clinical cases of epidemic encephalitis observed by him in Göttingen and nine cases anatomically examined. These cases have presented certain salient features, and Prof. Stern supports his views on their significance by quoting liberally from the literature and chiefly from the writings of his fellow-countrymen. This collated work is thorough and painstaking; it would have been of greater value if numbered references had been given to the articles of the authors quoted and if the bibliography had included all the authorities cited in the text. It is explained, however, that the last suggestion was ruled out on economical grounds.

The first section is devoted to prodromal and initial signs, the second section to symptomatology, In certain parts, such as in the article on the disturbances of sleep, the author evidently speaks from first-hand knowledge; his account, for example, of the lethargic state in children is of value and enhances our knowledge of the clinical manifestations; in other parts, however, he quotes the assertions and opinions of many neurologists without exercising critical acumen as to their relative importance. In treating of the changes in the cerebro-spinal fluid, the author draws the distinction between the changes found in acute and chronic forms of the disease, which J. R. Perdrau and others have recently observed. The section on the course and after-results of the malady is illuminating and might with advantage have been expanded, for Prof. Stern has studied carefully the after-histories of his cases. The section on pathological anatomy is as imperfect as an exposition of the subject as are the few pages on epidemiology and the more diffuse section on pathogenesis. Prof. Stern does not mention the fundamental and early researches of McIntosh and Turnbull into the pathology of epidemic encephalitis and the experimental production of the disease in animals; he errs in quoting as authoritative certain work on "filter-passers" which subsequent investigation has failed to confirm. Throughout the book Prof. Stern maintains the thesis of the close association of epidemic encephalitis and influenza, but his arguments and the nature of the evidence adduced fail to decide, conclusively, this disputed question.

The monograph is illustrated by a few photographs of actual cases, and has been prepared with much industry, while those sections of the clinical portion of the book in which Prof. Stern records his own observations make it an important contribution to the study of this complex disease.

George Moore.

A Portrait of George Moore in a Study of his Work. By John Freeman. London: T. Werner Laurie. 1922. Pp. 283. 16*s.*

Mr. Moore is an artist who has felt obliged to write, and who has been unable to write without revealing himself. His admirers read his successive books partly as stories in themselves and partly as instalments of the story of Mr. Moore. To those admirers Mr. Freeman's close and clever study may be cordially recommended.

Practical Plant Biology.

A Course of Elementary Lectures on the General Morphology and Physiology of Plants. By Henry H. Dixon, Sc.D., F.R.S., Professor of Botany in the University of Dublin. London: Longmans, Green and Co. 1922. Pp. 291. 6*s.*

An outstanding feature of this work is the remarkable amount of information conveyed within the limits of a modest volume. It consists of a series of lectures designed to illustrate the more important facts of morphology and physiology of plants in a manner suitable for medical and other students of elementary botany. Practical work is indicated at the close of each lecture. The types selected for study have been well chosen. Prof. Dixon deals first with unicellular organisms, and proceeds in an ascending series until the flowering plants are reached. While there are obvious difficulties in introducing minute forms of life to students unaccustomed to the use of the microscope, this order of study remains the logical one. Prof. Dixon sets an unusually high standard for medical students in treating so large a number of types in detail.

As a general introduction to the study of bacteria, Lectures VII. and VIII. may be cordially recommended. In his account of the ascent of the sap in Lecture XXV., the author gives without comment the cohesion theory with which his name is associated. This view has not received general acceptance, and quite recently Sir J. C. Bose has investigated the process and asserts that it is dependent on the active pulsation of living cells (*Nature*, April 29th, 1922, p. 561). The last three lectures are on general biological subjects, handled from a botanical standpoint. The concluding lecture on evolution and the theory of descent is one of the most fascinating chapters in the book and forms a fitting conclusion to a work which throughout is clear and lucid.

The Year Book of Pharmacy.

Edited by J. O. Braithwaite and C. H. Hampshire, B.Sc., F.I.C., with the coöperation of Thos. Stephenson, F.R.S.E. London: J. and A. Churchill. 1922. Pp. 546. 12*s.* 6*d.*

This useful annual publication contains a summary of all scientific work bearing upon materia medica and pharmaceutics published during the year July 1st, 1921, to June 30th, 1922, and also a full report of all the papers read at the British Pharmaceutical Conference held during July, 1922, at Nottingham.

The chemical abstracts occupy the first 176 pages, and deal with alkaloids, animal products, bacteriological and clinical tests, colouring matters, essential oils, fats, fixed oils and waxes, glucosides, ferments and sugars, gums, balsams and resins, inorganic chemistry, organic chemistry, and plant analysis. Under the heading of Materia Medica, brief notes are given about all the important new remedies that have been introduced during the year; this is followed by new applications of remedies and abstracts of papers on pharmacognosy, pharmacology and therapeutics. Pharmacy occupies the next section, the abstracts being classed under Dispensing, Galenical Pharmacy, Pharmacopœia Revision Notes, and Notes and Formulæ.

The transactions of the British Pharmaceutical Conference, 1922, fill the remainder of the book, and include the interesting and thoughtful address of the President, Prof. H. G. Greenish, upon Pharmacognosy and the Pharmaceutical Curriculum. A new feature is to be found in the compilation of the index, which is now divided into two parts—a subject index and an index of authors.

Leopold Auenbrugger's Inventum Novum.

Faksimile nach der ersten Ausgabe, begleitet von der französischen Übersetzung Corvisart's, der englischen von Forbes, der deutschen von Ungar. Herausgegeben und mit einer biographischen Skizze versehen von Dr. Max Neuburger. Wien und Leipzig: Josef Safar. 1922. Pp. 95, 51, 36, 72. £1 1*s.* 3*d.*

In The Lancet of Nov. 18th last we published a letter from Dr. Arthur Davies drawing attention to the fact that the year 1922 was the bicentenary of Leopold Auenbrugger, to whose genius we practically owe the introduction of the practice of percussion as a means of estimating the condition of the thoracic organs, and giving some account of the modest little work, a facsimile of which is now before us. It includes translations into French by Corvisart, into English by Sir John Forbes (1787–1861), and into German by S. Ungar.

Auenbrugger, who was born at Gratz in 1722 and who died in 1809, was physician to the Imperial and Royal Hospital of the Spanish nation at Vienna, and in that hospital he obtained the material for his conclusions, the results of seven years' observation and laborious and tedious exertions. The work is dated Dec. 31st, 1760, and appeared in 1761. Of its merits there is no need to speak nowadays; suffice it to say that Auenbrugger's work, together with the no less celebrated treatise on auscultation by Laennec (first published 1819), gave to modern medicine the only methods for accurate diagnosis of pulmonary conditions which existed until the discovery of X rays. Nothing is more easy than to be wise after the event, and it is not only astonishing that Auenbrugger did not hit upon auscultation, but that no one before his time had applied percussion as he did to the discovery and explanation of conditions existing in the chest cavity. In the "scholium" or note to the seventeenth section of the book, he points out that his plan is exactly the same as that employed to ascertain how full a cask may be, for casks "dum vacua sunt, resonant in omni puncto; verum repleta tanto plus sonitu suo destituuntur, quanto magis volumen aeris in iis contenti fuerit imminutum." Like many another work of great price the book and its contents fell flat at publication; Auenbrugger himself, with the modesty of the truly great, had confessed that there were many defects to be remedied, which, however, careful observation would remedy, and it remained practically unknown until Corvisart in 1808 published a translation, later (1818) republished as an appendix to the third edition of his "Essay on the Diseases and Organic Lesions of the Heart and the Great Vessels." Forbes's translation into English appeared in 1824 and that of Ungar into German at Vienna in 1843. Auenbrugger's original treatise has the directness and simplicity which also characterise such works as the Aphorisms of Hippocrates or the Principia of Newton, and the aspiration which closes the book has certainly attained in full. Here are his very words: "Cedant haec miseris in solatium, veris autem medicinae cultoribus in incrementum artis. Quod opto!"

Dr. Max Neuburger's historical sketch has the fullness and accuracy which his readers have learned to expect from him. It is pleasing to see that even in these times the memory of one who worked diligently to benefit his fellows is kept green by the labours of a dweller in a land which in common with most of Europe has been sorely stricken.

INFANT FEEDING.

Practical Infant Feeding. By LEWIS WEBB HILL, M.D., Junior Assistant Physician to the Children's Hospital, Boston; Assistant in Pediatrics, Harvard Medical School. London and Philadelphia: W. B. Saunders Company. 1922. Pp. 483. 24*s.*

WE have recently been called upon to review a considerable number of books on infant feeding; many have been excellent, a few have been indifferent, none has been better than the present volume. Dr. Hill's writing is sane and scholarly; he gives a lucid survey of the various important theories which have influenced opinion on his subject, and he preserves a personal view which is both critical and logical. Many of the foods whose analysis he gives are products not used in this country; the result is an increase in tables without advantage to the British practitioner, but the volume as a whole is so well written and attractive that it should enjoy a deserved popularity in this country as well as on the other side of the Atlantic.

Infant Feeding. Fourth edition. By CLIFFORD G. GRULEE, A.M., M.D., LL.D., Associate Professor and Acting Head of the Department of Pediatrics at Rush Medical College; Consulting Pediatrician to Provident Hospital and the Home for Destitute Children; Lecturer on Child Hygiene, University of Chicago. London and Philadelphia: W. B. Saunders Company. 1922. Pp. 397. 22*s.* 6*d.*

Dr. Grulee is one of the enthusiastic followers of the doctrines of Finkelstein, and his book has, in previous editions, found interested readers in this country. The new edition is chiefly remarkable for reproductions of charts illustrating the theories of von Pirquet, which, according to the author, "give us the essence of infant feeding." Finding these charts in the form in which they are reproduced, scarcely intelligible, we have submitted them to others whose difficulty has not been less than our own. We hope that the author will in the future correct this mistake, which must at present greatly diminish the value of his volume.

JOURNALS.

THE December number of the TROPICAL DISEASES BULLETIN contains reviews of 167 scientific papers, as well as of nine recent books and more noteworthy publications.—P. W. Bassett-Smith contributes an important review which reveals the advances made during the last ten years in tracking down the ætiological factors of some fevers of short duration; pappataci, dengue, and tsutsugamushi disease, Rocky Mountain spotted fever, Oroya fever, and verruga peruviana are adequately dealt with.—Under the heading of medical zoology A. Alcock reviews a large number of communications, ranging from protozoology to entomology.—Clayton Lane epitomises recent publications on malaria, while Warrington Yorke reviews sleeping sickness, including the four most recent papers from German and French sources upon the therapeutic action of "Bayer 205."

MADRAS CENSUS REPORT, 1921.

(FROM OUR OWN CORRESPONDENT.)

THE 1921 census report for the Madras Presidency has just been issued in three volumes. Vol. I. contains the census officer's report proper, and Vol. II. the imperial and provincial tables of statistics, while Vol. III. is devoted to provincial tables which give populations of taluks and divisions. "The first attempt to number the people of Madras appears to have been made in the year 1822 when the population of the Presidency was returned as a little less than 13½ millions." The present census returns the population as 42,794,155, as compared with 41,870,160 in 1911, or a 2·2 per cent. increase in the decennium, in contrast to an 8·3 per cent. increase between 1901 and 1911. This is the lowest rate of increase recorded since the census of 1881, when the Presidency was suffering from the effects of the great famine of 1877–78. Nine of the 25 districts have now a population of over two millions, Malabar district heading the list with a total of over three millions.

The census officer gives a brief survey of factors, such as rainfall and prices of grain, which during the past decade have exerted an influence favourable or otherwise on the population, and then proceeds to discuss the question of public health. During the early years of the decade and up to 1917 conditions were generally favourable, for the latter year the Presidency birth-rate being 32·4 per mille and the death-rate 26·2. The influenza epidemic of 1918 caused the birth-rate to fall to 28·9; while the death-rate rose to 43·1 per mille. By means of graphs it is shown that the Deccan was worse affected than any other part of the Presidency.

General Vital Statistics.

In discussing vital statistics generally the question is asked why both birth- and death-rates in Madras are lower than those in any other part of India. The report tries to answer this question and discusses it at some length. It appears from the available figures that Madras contains a smaller proportion of married women of reproductive age, and the number of female deaths per 1000 male deaths during the age-periods 5–15 and 15–30 indicates that the mortality of women before and at child-bearing ages is considerably higher in Madras than in any other province. While the report agrees with the Sanitary Commissioner's opinion that defective registration is responsible for the low rates in a number of districts, yet the conclusion is reached that, generally speaking, the registration of births and deaths in the Presidency does not appear to be badly defective. This opinion is considerably divergent from that expressed in the report of the Director of Public Health for 1921–22. In his summing up the census officer concludes that the low birth- and death-rates of Madras as compared with the rates reported in certain other provinces of India is mainly due to (1) the smaller proportion of married women at reproductive ages; (2) a great excess of deaths of women at these ages: (3) a constant flow of emigration on the part of males at these ages; and (4) possibly, in some measure, to constant in-breeding.

Influenza.

The influenza epidemic of 1918 is dealt with at some length. The increase in the actual number of deaths in that year was about 600,000, which is the number given by the Sanitary Commissioner in his report for 1918 as a moderate estimate of the number of victims. Most of the deaths were, of course, registered as "fevers," and in 16 out of the 27 districts the death-rate from fever rose over 100 per cent. above the average. In two of the ceded districts in the Deccan the increase was 1328·5 per cent. and 1410·0 per cent. respectively, the actual increase in the number of deaths being 55,000 and 41,000 in these two cases. The disease seems to have been considerably more fatal to females than to males in every district, and the common belief that the epidemic was particularly fatal to persons in the prime of life is corroborated by the figures given in a statement which compares the distribution of 1000 deaths by certain age-periods in the year 1918 with the average distribution of deaths over the five-year period, 1913–17. The great increase of deaths among persons at the prime of life naturally affected the birth-rate in succeeding years, and the birth-rate figure given for individual districts for the years 1918, 1919, and 1920 show conclusively that the birth-rate even in 1920 was still markedly below the average for 1913–17.

Infant Mortality.

The infant mortality-rate varied during the decade from 159 in 1920 to 231 in 1918, 1913 also showing the very high rate of 229. From the figures available in the report it is found that the highest rate of infant mortality is recorded in those districts which in other respects are generally considered among the most advanced—e.g., Madras, the Nilgiris, Tanjore, Tinnevelly, and Chingleput. It must be remembered that Madras is a densely populated overcrowded city, but as the report states, the conditions of city life do not "excuse Madras for showing in 1920 male and female infant mortality-rates of 290 and 275 when the rates for the Presidency are only 173 and 146." It is apparent from these figures that the child welfare scheme which has been in force in Madras city for the past five years has as yet merely touched the fringe of its problem.

Emigration.

An important factor affecting the population of the Presidency is emigration. On the balance of emigration and immigration Madras has lost one and a half millions of her natural population. The actual figure is probably much in excess of this, as complete returns were not available when the present report was written. "Thus summing up the conditions of the decade, we find that after a succession of comparably favourable years, the year 1918 was bad from the point of view of public health, from the point of view of failure of rain and consequent scarcity, and from the point of view of prices. The influenza epidemic of this year is the dominating influence of the decade; not only did it take a heavy toll of the people directly, but by causing the death of persons, especially women, in the prime of life, it has seriously affected the birth-rate in subsequent years. Moreover, scarcity combined with high prices led to extensive emigration. Thus it is not surprising that the census of 1921 gives results very little in advance of those of 1911 and that in some districts the population has gone back."

Density and Variation of Population.

A series of maps is given at the beginning of the report showing density of population, and variation in that density between 1911 and 1921, in each district, &c. The mean density of the Presidency is 297 to the square mile, and at this figure Madras stands fourth among the greater provinces of India, Bengal, the United Provinces, and Behar and Orissa taking the first three places on the list. The variation of the population during the decade was influenced by (1) the influenza epidemic and (2) the conditions of scarcity—in some places approaching famine—in the Agency, Ganjam, and the Deccan in 1919 and 1920. The figures given in the report for rainfall and area under irrigation show that the Deccani districts are terribly handicapped by the lack of rainfall and "to this natural handicap—or is it a direct consequence of it?—is added the almost perpetual scourge of epidemic diseases." These facts are reflected in the census figures. Kurnool has lost 2·2 per cent. in population during the decade, while Bellary district has lost as much as 11 per cent. In the table giving proportion of population per mille who live in towns, Madras stands second to Bombay with the figure of 124. Three places in the Presidency—Madras, Madura, and Trichinopoly—come within the Government of India's definition of a city, having a population over 100,000. The population of Madras has increased by only 1·6 per cent., that of Madura by 7·8 per cent., while that of Trichinopoly has fallen by 7·5 per cent. It was pointed out in the 1911 census report, and still holds good, that urban life appeals to the Tamils more than to the other peoples of the Presidency.

Age and Sex Distribution.

In the chapter on age the census officer has some interesting observations to make. In the first place he gives two diagrams which show most graphically how erratic the returns of age are, "the tendency to return the age as a round number, especially as a multiple of ten or five," being due to the fact that "the great majority of the population does not know when it was born or what its age is." Tables and diagrams are given comparing the present age-distribution with that in 1871, and at each subsequent census. For instance, the returns of 1871 and 1921 show a remarkable contrast. Not only was the number of children in 1871 greatly in excess of the number now, but at each age-period from 10–15 upwards, if there is a rise in 1871 there is a fall in 1921, and vice versa. In the loss of children in 1881 we see a consequence of the great famine of 1877–78, and it is remarkable how closely the curve of 1921 corresponds with that of 1881. In each of these years the population was just beginning to recover from a severe shock. A table giving the age- and sex-distribution per 10,000 persons in Madras city, other cities, towns, and villages, shows a great amount of immigration to the city of Madras and in a lesser degree to other towns and cities by persons of both sexes at ages 20–30. At the same time the overwhelming proportion of rural to total population is clearly marked by the almost exact resemblance between the age-distribution of the population of the whole Presidency and that of the rural population. As regards sex, Madras population has, since 1881, continued to show a preponderance of females to males, in this respect differing from most of the bigger provinces of India. From 1881–1911 there was a steady rise in the proportion of females, but during the last decade there was a slight set-back, the proportion falling from 1032 to 1028 females per 1000 males.

Other Details.

Other chapters in the report deal with the questions of literacy, language, civil conditions, infirmities, caste, tribe or race, and occupation and industries as revealed by the census figures, and are illustrated with the usual tables and graphs. The superintendent of census operations, in his introductory chapter, alludes to various difficulties experienced in making a census of a population which is largely illiterate. In addition, the Moplah rebellion and the non-coöperation movement were factors which could not be ignored, but all difficulties seem to have been successfully overcome, and the present census report may be said worthily to follow its predecessors.

THE LANCET.

LONDON: SATURDAY, JANUARY 13, 1923.

THE SURGERY OF INFANCY.

THERE is a widely held belief that the physiological economy of the child, and especially that of the infant, resents the affront offered by a surgical operation more acutely than does that of the adult. It is particularly regarded as a serious adventure to perform a laparotomy in an infant, where much intra-abdominal work is likely to be called for. To obtain a right perspective in this matter is not easy, for intestinal resections, anastomoses, and excisions of such viscera as the gall-bladder are rarely required in children under the same conditions as in adults. At first sight, the increased severity of these operations in the young would seem to be proved by the mortality following, for example, the resection of irreducible intussusception, or the division of the pyloric sphincter for hypertrophic stenosis. Dr. L. G. PARSONS and Mr. S. G. BARLING, elsewhere in this issue, relate their experiences of this latter operation and report a mortality of 48 per cent. for this seemingly simple procedure. These results, which are actually under, not over, the average mortality in skilled hands, would seem to justify us in taking a grave view of operations upon the very young. But a consideration of a wider operative field will not lend equal support to this view. Indeed, many surgeons would not subscribe to it; on the contrary, they would be ready to affirm that the young withstand operative insult to their physiology better than the fully grown, provided that certain precautions are scrupulously observed.

The conditions prevailing in operations upon small children are less favourable than in adults for several reasons which depend wholly upon their diminutive proportions compared with the operator and his instruments. The incision for a laparotomy has to be relatively longer than in the adult. This entails a larger exposure of the abdominal wall and the consequent larger heat-loss, whilst the severance of a greater number of sensory nerves is more conducive to shock. But of more concern than this is the fact that a larger area of peritoneal-covered surface is subjected to the nocuous influence of the manipulations necessary to carry out the intended procedure. Again, a loss of blood which is insignificant in an adult may easily be a measurably great fraction of the total blood volume of a child. Yet, despite these drawbacks, children recuperate after severe operations much better than adults because of the more than counterbalancing favourable factors. The child has a greater margin of reserve than the adult, his tissues are more capable of adaptation of function and more vigorous in repair, his hæmopoietic system exhibits greater activity, and his comparatively undifferentiated nervous system is less mobile and less unstable. The truth of this contention is the more evident if the course of events after operations for abdominal injuries in children be remembered. The recovery is often surprising in its occurrence and amazing in its rapidity.

Why, then, should Rammstedt's operation possess such a high mortality rate? There are several reasons, but the greatest of all is that the infant with hypertrophic stenosis is a starved animal with a resistance to trauma, to shock, to infection of the intestinal mucosa at a low ebb. The operation is usually performed under the worst possible circumstances, medical measures having been tried and found wanting. If the recommendation of Dr. PARSONS and Mr. BARLING to consider this disease a surgical one from the beginning were accepted generally, undoubtedly the mortality would fall considerably. These two observers in seven consecutive private patients carried out the operation without a death, an indication of the good results to be anticipated in the hands of practitioners who have ceased to regard the disease as a primarily medical one. Division of the pyloric muscle ring is the ideal procedure for congenital hypertrophic stenosis. It causes a relaxation of the sphincter which lasts just long enough for a cure to be effected; the two cut ends after some months are usually found to have united by a simple linear scar whenever an opportunity has occurred to make such observation. This temporary relief is all that is desirable, for, invariably, with the passage of time, in children who survive early infancy, the normal relation between the strength and size of the sphincteric and general gastric musculature is established. The factors of success in operating upon young children are above all gentleness in the manipulation of their delicate tissues; speed, if this does not entail roughness; the avoidance of the loss of one drop of blood more than is necessary; and an inflexible determination to diminish the intra-abdominal trauma and the exposure of the viscera to a minimum, whilst every possible heat unit in the child's body is conserved.

◆

HOSPITAL REPORTS.

WE reviewed recently the latest volume of the St. Bartholomew's Hospital Reports, which have appeared yearly, except for a short intermission during the war, since 1865. Similar reports have been published regularly by Guy's Hospital since 1836, and by other hospitals for longer or shorter periods, though in some cases they have consisted only of statistical tables. It may be doubted whether the publication of tables by individual hospitals serves any useful purpose, and we notice that they do not find a place in the volume now issued by St. Bartholomew's Hospital, but the whole question of the value of hospital reports is worth a little consideration. Their appearance has been taken for granted, while their contents seem to be fortuitous. Many important contributions to medicine and surgery, under names that have now become historic, have first made their appearance in such reports, if only because, at the times when the publications were instituted, medical and surgical periodicals were largely non-existent, and the younger men, whether attached to the great hospitals or enjoying good opportunities for acquiring experience, had far fewer opportunities to put their work before their colleagues. At the present time work of merit can find publication in one of the general or special medical journals, so that at first sight the necessity seems no longer to exist for the multiplication of volumes from the separate hospitals. But we do not feel at all clear upon this point. Even if the records of a great hospital tend to be read only by past students of the school responsible for their issue, they have an excellent *raison-d'être*, while in hospital reports there is a flexibility which may be absent at any particular time from the overcrowded pages of a medical journal. We have noted frequently that when some main statement of principle is being enunciated in our own columns, a reference, for the sake of the details, is given to a volume of hospital reports. This being so, no one need hesitate to give of his best to be "buried" in a volume of hospital reports, because resurrection is a certainty when the article calls for it.

But if hospital reports are to maintain a high standard, the traditional pride in their publication must be fostered. This difficulty has been met at the Mayo Clinic, for example, by the yearly publication of a volume containing a collection of papers which have already appeared in many different journals, but which had their inspiration from the Clinic. There would, however, be no need for any British medical school, giving signs of active life, to look outside its own organisation for the production of a yearly volume of new and valuable matter, which would be an index of the activities yearly, nay hourly, being carried on within its hospital. There will always be subjects for literary treatment, whether historical, statistical, biographical, clinical, or purely scientific, worthy to be printed in the archives of the institution, though some of them would be unsuitable for publication elsewhere for numerous reasons, some of which will immediately occur to the mind. A valuable article may, moreover, be offered to the hospital reports purely owing to the writer's loyalty to his own school, though he knows that it would be eagerly accepted elsewhere; in such a case references in literature of a wider appeal will call attention to it, and incidentally to the volume in which it appears. What has to be recognised is that only loyalty on the part of past members of a school will enable hospital reports to maintain a worthy existence. The matter must be supplied for the most part by those actively engaged on the staff of the hospital; the subscriptions must be furnished largely by old students who have gone out into the world, but who wish to maintain some link of communication with the school that bred them. We are glad to see that St. Bartholomew's is still able to maintain a high standard in its reports in spite of present difficulties introduced by the costs of production. The current issue, as we said in our review, is the first for which the medical school is responsible, former issues having been edited and published by a committee made up of members of the staff. We learn that previous to the appearance of this present volume there was a question as to whether reports should be published at all, but publication was finally decided upon. The question is not so much whether hospital reports should be published, but as to what material they should contain. The bulk of the volume will consist of summaries of the work done in the hospital along some definite lines, the articles recording with circumstance and detail the experiences which have been met with in the institution, and the general lessons to be drawn from them. For over eighty years the Guy's Hospital Reports have provided an admirable example of this form of report, and under the editorship of Dr. A. F. HURST the standard is steadily maintained. Statistical tables must, of course, form a proportion of these records, but we doubt their scientific value. It is not the bare figures that are wanted, but the reasons for their significance, and these should be put forward with every measure of proof that can be taken.

There is a side to the records of a hospital which it seems to us might be developed. Most people know of the existence of, and some have even read, the old monastic chronicles of abbeys and priories, those, for instance, of St. Albans, Jocelin of Brakelond's work dealing with the Abbacy of Samson, the Chronicles of Glastonbury and Lanercost. In such chronicles we have recorded brilliant pictures of the working of a great society, of social customs, estate matters, agriculture, Poor-law and so on, which bring the lives of our forefather vividly before us. Would it not be possible for a hospital to keep a modern chronicle, and issue portions of such chronicle as a hospital report? Most large hospitals have an interesting social story. Medical and surgical matters, also, need not always be considered from the purely professional point of view, but as matters affecting our fellow creatures and from the patient's point of view as well as that of the staff. Papers on the economics of the hospital written by the steward or bursar should find regular acceptance—the hard-worked and resisting official should be goaded to supply them. All who knew him can imagine what interesting matter the late steward of St. Bartholomew's Hospital could have put upon paper, and the contents of a book recently published by the chairman of the London Hospital would have brightened up the records of that great institution in a wonderful way. Hospital reports in their present form are read by but few—perhaps by none of those who subscribe to hospital funds. Far more persons would take an interest in hospitals if the reports were more direct and simple in their appeal, and judicious excerpts from the minutes of governors' meetings, revealing the nursing and domestic side of hospital life might lead to valuable pecuniary response. The working of a great hospital is of abiding interest, and we believe that, if some course such as we suggest were adopted, volumes of hospital reports, if not ranking among "best sellers," would appeal to many persons who do not now buy them and that thereby hospital incomes might be increased.

◆

CARBON MONOXIDE IN COAL-GAS.

THE fatal results of leakage from a main supply pipe in Bethnal Green have recalled public attention to the lethal properties of coal-gas. It is perfectly well known that carbon monoxide is the poisonous constituent. The Gas Regulation Act of 1920 gave the supplying companies no greater latitude than was enjoyed previously in regard to the percentage of carbon monoxide in the gas supplied. A departmental committee, appointed in 1898 by the Home Office, had recommended that the percentage should be limited to 12, but no legislative action was ever taken to give effect to this recommendation. The Local Government Board, however, made it a practice in approving loans to local authorities to require that the gas supplied should not contain more than 15 per cent., although no steps were taken to ensure that this limit was adhered to. What the Gas Regulation Act did was to give the Board of Trade authority to depart from previous practice and to prescribe a limit, if, after due inquiry, it thought wise to do so. A committee, of which Sir WILLIAM PEARCE was chairman, and Dr. T. CARNWATH the medical member, came to the conclusion, after careful consideration, that—on the evidence at present available and having regard to what is likely to be the trend of development in the gas industry during the immediate future—it was inadvisable to impose any limit. The departments concerned, however, were put on their guard carefully to watch the situation so that, if the freedom from limitation were accompanied by unexpectedly unfavourable results, the attention of Parliament should again be directed to the matter.

There is an impression abroad that gas companies have availed themselves liberally of their right to admix water-gas. What are the facts? The gas supplied by the South Metropolitan Gas Company contains no admixture of water-gas, and, speaking for the larger gas companies generally, there has been no material change of practice as regards the proportion of carbon monoxide supplied during recent years. The proportion of carbon monoxide in the gas supplied by the Gas, Light and Coke Company has averaged about 15 per cent. for the last twenty years. That supplied in 1919 gave an average percentage of 15·17 for the year; the Bethnal Green accident occurred on the night of Dec. 28th/29th—on the 28th the percentage was 14·8, and on the 29th it was 15·0. There can be little doubt that for several hours before the discovery was made, the concentration of gas in the air of the room in which the deaths occurred was so great that the issue would have been fatal even had the gas been "straight" coal-gas containing only 8 per cent. of carbon monoxide.

The suggestion that the gas now supplied has not such a characteristic smell as formerly seems to be devoid of foundation, although it may have been true to some extent of those supplies from which toluene and benzene were extracted during the war. The characteristic smell of coal-gas is due in the main to heavy hydrocarbons and to certain little known sulphur and nitrogen compounds; the smell of carburetted water-gas is even more penetrating than that of ordinary coal-gas. By the Gas Companies (Removal of Sulphur Restrictions) Act, 1906, the restrictions with regard to the presence in gas of sulphur compounds, other than sulphuretted hydrogen, were abolished. In practice, however, gas companies are careful to remove sulphur as completely as possible owing to its injurious effect on pipes and fittings. The great bulk of the sulphur in crude gas is present in the form of sulphuretted hydrogen; of the remainder, which averages about 40 gr. per 100 cub. ft., some 34 gr. are in the form of carbon bisulphide and 6 gr. in the form of obscure compounds which cannot be removed by any known method. Opinion in this country is opposed to the addition of any extraneous substance to give to coal-gas a tell-tale smell. Its peculiar odour is now so well known as a danger signal that the substitution of another odour would be unwise. Such a substance would anyhow be hard to find, for it must be easily perceptible in low dilution and the smell should vary with its concentration in the atmosphere and disappear as soon as the leak was remedied and the escaped gas dissipated. Further, it should be insoluble in water and should not be readily removed by earth or other adsorbent substance. As the outcome of experiments carried on in America by **KATZ** and **ALLISON**, under the auspices of the Bureau of Mines, certain mercaptans and pyridine were suggested as stenches, but it is impossible without extensive trial to say whether they would be found of practical value.

However much we may regret the occasional cases of accidental gas poisoning, it is difficult to see how they can be avoided by prescribing its composition. Careful inquiry into 114 fatal cases of gas poisoning during the past year has shown that in only 22 cases did the percentage of carbon monoxide exceed 16. In no case did it exceed 20 per cent. It would be idle to deny that an increase in the proportion of water-gas must almost necessarily be accompanied by somewhat greater risk to the consumer. From the medical point of view the question for consideration is whether this increased risk is more than counter-balanced by the advantage of a clearer atmosphere. Much of the risk can be obviated by more careful attention to mains and fittings and by greater promptitude in the notification of escapes. In Bethnal Green the smell of gas was clearly perceptible on Dec. 28th, and an occupant of one of the houses wrote to the gas company complaining of the smell. If this information had been telephoned, or notified to the police, the tragedy might have been averted.

INDEX TO "THE LANCET," VOL. II., 1922.

THE Index and Title-page to Vol. II., 1922, which was completed with the issue of Dec. 30th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2.

Annotations.

"Ne quid nimis."

COMPENSATED LAMENESS.

THE 15-mile flat race recently organised by the proprietors of the *Star* for men with one or more artificial lower limbs was a remarkable object-lesson of compensated disability. We understand that Mr. F. G. Ernst, the orthopædic mechanician, originated the idea of such a walking race. Out of 300 or more entries 264 actually started and of these 196 finished the course. We have been favoured with a complete list of those who finished, with the time occupied, and an indication of the type of limb worn. The winner completed in just under three hours—that is, an average speed of over five miles an hour—the second being less than five minutes behind. Both of these men were below-knee amputations, the stump being about ten inches long, and both were wearing "Rowley" wooden limbs with ball-bearing joints and sponge-rubber feet. Ten of the leading group of walkers exceeded a speed of six miles an hour for some part of the course, and the winner covered the first mile and a half in 14 minutes 5 seconds. There were about an equal number of above-knee and below-knee amputations among the walkers, and naturally most of the early places were taken by men who still possessed a natural knee-joint, but the forty-eighth place, with the excellent time of 3 hours 33 minutes, was taken by a man with an amputation above the knee, wearing a "Desoutter" metal limb. The difference was not, however, very great, for taking a comparable group of 25 men wearing limbs of the same make, the average time of 15 below-knee amputations was 3 hours 42¼ minutes, and of 10 above-knee amputations 4 hours 14½ minutes. A man with double amputation below the knee came in eighty-eighth in the astonishing time of 3 hours 49 minutes; he was wearing two "Grossmith" wooden legs. We are informed that another double amputation was making even better time until chafed by a strap near the finish. Among the last six to arrive were two men with disarticulation at the hip-joint, and a third with a stump so short as to require the misnamed "tilting-table," who, in spite of this major disability, had covered the 15 miles in five hours. Of these one was wearing a "Grossmith" wooden, one an "Ernst" wooden, and the third a "Hanger" light metal limb. A lad of 15 excited enthusiasm by coming in at 4 hours 29 minutes on a wooden peg leg. In regard to the apparatus responsible for these remarkable results, even a casual glance at the records suggests that different makes and types of limb are very evenly distributed over the race, and the opinion is confirmed that any prejudice against wooden limbs is not justified in fact. Metal limbs have only been issued in any quantity during the last year or so. The claim is made for the heavier wooden limb that advantage is gained from the "pendulum" action, owing to which the foot swings forward by its own weight with less of conscious exertion—and there was nothing in the race to refute this claim. It is, however, a little difficult from the records to ascertain exactly the proportion of wooden and metal limbs worn, since some of the makers supply both. In 18 cases the nature of the limb is not stated at all, and of the remaining 188, as far as we have been able to ascertain, not more than 30 were of metal. A few were wearing the new Desoutter limb, which has a wooden socket for the reception of the stump, the remainder being of the standard metal pattern. To walk 15 miles is an achievement in itself; to do so in five hours with a disarticulated hip-joint on a course with a long up-hill rise at the finish is an exhibition of endurance and pluck which must command respect for both the human and the physical element. It was generally admitted that the majority of the men suffered little or no bad effects from their strenuous walk. Most of those who fell out did so as a result of mishap either to artificial leg or boot; one hero who fell unconscious by the way and was picked up by two official timekeepers, insisted on resuming his course when he had rallied. It would be interesting still further to analyse the results into short, medium, and long stumps, but the material is hardly sufficient for this purpose. No more can fairly be said in regard to the advantage of different types of limb, as the results of such a race would be affected by the probability that only those would enter who had confidence in limbs which they found useful.

THE SIGNIFICANCE OF STRIÆ ATROPHICÆ.

Striæ atrophicæ are common pathological objects attracting little attention, inasmuch as they cause the patient no distress, and from the site of their occurrence give rise to slight disfigurement. Their formation is generally considered satisfactorily explained on the theory that they result from a previous distension and stretching of the skin. A very unusual example is recorded by MM. E. Rist and P. Jacob in the *Bulletins et Mémoires de la Société Médicale des Hôpitaux de Paris* for Dec. 14th, 1922. The patient was a girl of 17, suffering from tuberculosis of the right lung. For this a right-sided artificial pneumothorax was established in February, 1922, about three months after the apparent onset of the disease. A week later numerous striæ atrophicæ were observed situated on the left side of the chest, the left loin, and buttock. They were particularly numerous over the lower two-thirds of the left thorax and in the left lumbar region, and ran in a direction parallel with the ribs. In the following August they still presented the reddish-purple colour of recent striæ, but when the case was exhibited in December they were of a pale rose colour, with the typical mother-of-pearl appearance. Mr. Balzer has previously pointed out that striæ atrophicæ may appear over the chest in cases of pleural effusion or of pneumothorax, usually on the homolateral side, rarely on the contralateral side, as the result of a slow and progressive stretching of the skin. MM. Troisier and Menetrier have shown that the histological changes consist of an elongation and stretching of the cutaneous elastic fibres, with here and there rupture. In the case here recorded the establishment and maintenance of the right-sided pneumothorax resulted in a secondary enlargement of the left side of the chest, yet the striæ appeared so rapidly that no marked distension could have taken place when they were noted, and further, enlargement of the thoracic cavity could hardly account for their formation in the skin of the shoulder and buttock. The authors put forward the suggestion that in some instances there may be a specific predisposition to the development of striæ atrophicæ, a peculiar condition of fragility of the skin. Another explanation, however, offers itself, that the striæ result from external pressure as opposed to internal distension. In support of this theory certain examples may be quoted. In a large proportion of men who have served in the army striæ atrophicæ are seen over the anterior aspect of the shoulders, corresponding in position with the shoulder-straps of the army pack, and in nearly every instance in which these are present the man wore a pack during his service. Again, a girl of 17, also suffering from pulmonary tuberculosis, showed striæ atrophicæ over the back, just below the ribs on the left side. They were of bluish-red colour, indicating a recent formation. No history of illness confining the patient to bed, and no habit of sleeping on one side of the body could be obtained, whilst the unilateral distribution seemed to negative clothing as the provocative agent. It was found that the patient had slept two nights previously on a "hair-slide," and on waking had noticed that her back felt sore. The correspondence between the size and shape of the "hair-slide" and the marks on the patient's back left no doubt as to their origin. It is also a possibility that the striæ that develop upon an abdomen which has suffered enlargement are similarly caused by external pressure creasing the skin, due to the constricting effect of clothing or of binders, and that in those rare instances of parous women in whom no striæ are seen the external pressure effects of clothing were slight. It would be interesting to know whether in the case recorded by MM. Rist and Jacob any history of external pressure could be found, such as the position adopted on lying in bed, or the constriction of clothing, to account for the contralateral appearance of the striæ atrophicæ.

THE EFFICIENCY OF LINEN WEAVERS.

THE investigations of the Industrial Fatigue Research Board continue to throw light upon the way in which conditions of work, by influencing the human factor, affect productivity. The most recent report deals with linen weaving [1]; in it attention is particularly directed to atmospheric conditions with regard to temperature and humidity. In weaving the loom rather than the weaver determines the pace, which is only limited by the tendency of threads to break when the weaver has to tie up the broken ends. The thread of flax from which linen is woven, like that of cotton, weaves best—i.e., breaks least often—in a warm humid atmosphere; but the activities of the weavers are adversely affected when the warmth and humidity are such that they perspire freely as they work. There is thus an antagonism between the weavers and their materials; and the result of the inquiry shows that the economic limit for linen weaving is reached at a wet bulb of 73° F., above and below which productivity falls off. Two other factors were also investigated—viz., lighting and hours of work. Artificial light, even though the actual illumination (between 5 and 8 foot-candles) was good, was found, when compared with daylight, to reduce output by 11 per cent. No definite conclusions as to the optimum hours of work could be drawn from the shortening of hours, which took place owing to trade depression, from 45 per week to 40, then to 36, and finally to 27, owing to the complexity of the factors concerned, which were largely psychological. The report, which is one of a series devoted to the textile industries, is interesting and gains much from conciseness in writing.

CARDIAC TREATMENT AT A BOHEMIAN SPA.

THE recent medical congress at Franzensbad in Czecho-Slovakia (or Bohemia as we may still call the country for the sake of medical continuity) attracted medical men from all parts of Austria, Bohemia, and Germany, and led to a useful exchange of views upon the scientific basis of cardiac treatment. R. Schmidt (Prague) spoke of the effect of "drop-heart" in lowering resistance to infection, intoxication, and narcosis. Bradycardia he found often associated with gastric disorder and albuminuria. He still upheld the existence of a uric-acid diathesis, which played a large part in the production of arterio-sclerosis. H. E. Hering (Cologne), while admitting the influence of extra-cardiac impulses upon the heart, gave himself out as a frank adherent of the myogenic origin of cardiac failure. Respiratory irregularity of the pulse, normal in the young, he regarded as of serious import in older persons. In cases of increased blood pressure associated with tachycardia, in which cold carbonic-acid baths proved helpful, doubtless the balance of internal secretion was at fault. O. Minkovski (Breslau) dealt further with the very intimate relation between metabolism and circulatory disorders. Carbohydrates were of notable value as rapid sources of cardiac energy, and injections of glucose had proved helpful in cases of insufficiency. An abnormally small heart was often due to pulmonary tuberculosis, hypertrophy to arterio-sclerosis, renal sclerosis, or gout. He regarded obesity as becoming pathological only when it occasioned cardiac disturbance, fatty accretion around the heart having little direct effect on the circulation. Heart attacks in the gouty were probably due to toxic causes acting on the myocardium, not necessarily irremediable in nature. K. Zörkendörfer (Prague) called attention to the installation in Franzensbad of concentrated sodium-sulphate springs, the water being isotonic with body fluids; these had a useful alterative and osmotic influence on the body. The low conductivity of the peat baths permitted the application of high temperatures to the skin. J. Pál (Vienna), discussing the pathology of hypertonus of heart and arteries, expressed doubt of the value of iodine except in syphilitic cases, sodium rhodanide (rhodanol) being indicated otherwise. In the differential diagnosis of cardiac defects F. Volhard (Halle) urged a plea for greater attention to functional capacity rather than auscultatory signs, the loudness of a murmur demonstrably bearing no relation to the amount of organic defect. The state of the hepatic circulation and venous pulsation in the neck were nevertheless of importance. v. Jaksch (Prague), dealing with the result of infections upon the heart, extolled the value of digitalis combined with calcium followed by injections of sugar, camphor, or ether, and later by the use of cold carbonic-acid baths. Altogether the conference was a practical one, and drew useful attention to the new developments of a famous centre in cardiac treatment.

CENTRAL EUROPEAN UNIVERSITIES AFTER THE WAR.[1]

A VISIT of a party of members of the University of Oxford to the chief seats of learning of the five central European countries during the summer term of last year had for its main object to obtain personal insight into the conditions prevailing among students of their own age at educational centres situated in war-ruined capitals. The party further determined to conduct propaganda on behalf of European students in Oxford, and, if possible, through a wider circle. Such a movement would, it was hoped, establish a precedent in English universities under which definite attempts could be made to promote understanding between the rising generations of European countries. Captain C. P. Blacker, of Balliol College, Oxford, who conducted the expedition, has now set down in a pamphlet, with the above title, the results of the tour, and makes a moving appeal on behalf of the groups which he visited with his party.

The conditions in Austria, as seen from the student's eye, testify to the devastating effects of the war. In Vienna the Viennese of the upper and middle class have given place to foreigners who can profit by the exchange and make a public appearance in the former centres of pleasure, while the natives try to hide their poverty by self-effacement. Some, including prominent university professors, have found suicide the only way out of their miseries. What applies to Austria in regard to poverty applies, more or less, to the other countries visited—namely, Hungary, Czecho-Slovakia, Poland, and Germany. The effects of post-war conditions on child life is strikingly shown by a comparison of pre-war with present records in certain schools, not the poorest, of Berlin. Out of 607 children, 360 at the age of 14 were incapable of undertaking work of anything like an exacting nature, while the pre-war returns show only 8 per cent. incapable of undertaking such work. But, despite the horrible environments, the students of the universities show everywhere keenness for work, and while fighting the wolf from the door they find means, with the help of the European Student Relief, for carrying on their education under the most adverse conditions. This applies in measure to women as well as to men. The students undertake the most menial forms of labour to achieve their purpose, and self-help and coöperative societies are springing up everywhere. A remarkable instance, which, as the author remarks, deserves the closest attention of the English undergraduate, is the Hungarian "Centrum Students' Society," which has had an amazing career. Founded in January, 1920, with a capital of Kr.4500, this sum was increased in six months to Kr.500,000. In 1921 the value of what was sold amounted to Kr.21,000,000, and the turnover has now quadrupled, notwithstanding the decrease in money value by one half. At the beginning of 1920 there was a single shop. Now there are laundry, tailoring, shoemaking and repairing establishments, a clothes shop, two milk shops, a barber's shop, and a grocery, while other schemes are being developed, including the production of an undergraduate newspaper. Everything can be bought 30 per cent. cheaper than in any of the town shops.

The book ends with an appeal for all countries to take a keener interest in each other, an interest which seems already to be springing up among students on the continent and which, for want of a better term, has been called "generation consciousness." To foster this among students it is suggested that a certain amount of foreign travel and a knowledge of foreign countries should become a recognised part of a university man's equipment. The idea is an excellent one, and Captain Blacker has written a valuable pamphlet, while it is interesting to note that the whole trip with which the author deals could have been made by any individual member for £20.

---

[1] Gloucester: Crypt House Press. 1922. Pp. 64.

REPRODUCTION IN CELL-COMMUNITIES.

IT is known that the rate of multiplication of bacteria is for a time proportional to the concentration of the food material and to the number of the organisms, and that later the multiplication becomes slower and finally stops. The inference seems to be that the multiplication is governed by the amount of food available. T. Brailsford Robertson,[1] however, finds that there are other factors to be considered. When two individual infusoria are isolated into the same drop of culture-medium, the rate of reproduction of new cells is much more rapid than it is when a single individual is isolated into a drop of the same size. It may be 16 times as great. The author calls this the "allelocatalytic effect." He finds that distilled water, to which a proper reaction and tonicity have been communicated by the addition of a buffer mixture of phosphates, and which has been densely populated by dividing infusoria, contains a substance which enhances the multiplicative rate of isolated infusoria. The autocatalytic character of reproduction in cultures of infusoria is attributed in part to the inherent capacity of each cell to reproduce itself, due to the presence within it of a catalyser capable of effecting protoplasmic synthesis, and in part to the shedding of a catalyser into the surrounding medium, through the agency of which the cells are enabled to facilitate each other's reproduction. An old culture-medium contains no substances which are toxic for infusoria, nor does it retard the multiplication of infusoria isolated into it from young cultures. Nevertheless, infusoria from old cultures develop much more slowly in old culture fluid than in fresh isotonic hay infusion, and the maximal resultant population is very scanty. During the lag period which succeeds isolation of an infusorian into a fresh culture-medium, and before the first division has occurred, the organism is insusceptible to the action of agents which accelerate multiplication. The acceleration of reproductive rate is observable only after division of the isolated cell. The accelerative agent in cellular multiplication originates in the nucleus, and the autocatalytic time-relations which distinguish all types of growth are referable to the fact that nuclear synthesis is autocatalysed. Brailsford Robertson suggests that, during the periods between nuclear divisions, each nucleus retains the charge of autocatalyst with which it was originally provided, and adds to it in the course of nuclear synthesis which is rendered possible by its presence. At the next division, the autocatalyst is shared between the nuclear materials and the surrounding medium in a proportion determined in part by its affinities for chemical substances within the nucleus. At the end of this redistribution the autocatalyst stands in equilibrium between the external solvent medium, on the one hand, and on the other hand the nuclear substances with which it is combined, or in which it dissolves. The nuclear membrane is then re-formed, and the autocatalyst within the nucleus is again shut off from disposal.

CONGENITAL OSTEO-SCLEROSIS.

Dr. Ralph K. Ghormey,[1] of the orthopædic service of the surgical department of the Johns Hopkins Hospital, reports the following unique case. A boy, aged 8, was brought to hospital for pain in the left hip and limp. On examination he presented slight atrophy of the left thigh and calf, and in the recumbent position there was about ½ cm. of apparent shortening of the left leg. Voluntary as well as passive movements of the left hip revealed slightly less abduction than on the right. There was a slight decrease in hyperextension of the leg. Skiagrams of the pelvis showed a curiously dense appearance of the bones, and a similar condition was found throughout the skeleton. The vertebral bodies showed a marked density at either pole, there was thickening of the cortex of the ribs and this was more definite in the case of all the long bones, most marked in the femora and humeri and greater in the proximal portion than in the distal extremity of these bones. The skull was thicker than normal. Skiagrams of the parents showed that while the mother's bones were normal, practically the same condition existed in the father as in the child. The Wassermann reaction was negative both in the parents and the child. Although there are several cases on record in which osteo-sclerosis has been found at autopsy, some of which cases were congenital and others were associated with changes in the blood-forming organs, especially leukæmia, Dr. Ghormey has been unable to find any cases similar to his own in the living person. Most writers are of opinion that the sclerosis is secondary to an irritation connected with the morbid process in the blood. In the present case, however, there was a definitely inherited condition not related to any demonstrable metabolic disturbance.

SPONTANEOUS DEGRADATION OF CULTURE.

Under this title Prof. Tenney L. Davis, of the Massachusetts Institute of Technology, puts before the readers of *Science Progress* a theory of the rise and fall of cultural communities. Progress of culture comes about—this is his thesis—through changes of idea-system, which in turn are accomplished by the ideas of individuals. The stimulus to the individual comes from his difficulties, and the most fertile period in the cultural development of Europe was "a period of vice, disease, brigandage, pride, pomp, and superstition, a time when often men dared scarcely call their names their own." As Prof. Davis says, individuals get bright ideas as the result of being subject to predicaments; but there is a golden mean, and a supply of stimulating predicaments must be balanced by that organisation and regulation which allows the thinker a certain security of nourishment and undisturbed sleep. The civilised group thus devises means for the easier spread of civilisation, whilst the complexity of the group increases the variety of predicaments to which an individual can be subjected, so promoting changes in the group's idea-system. So far the argument contains nothing novel, as Prof. Davis remarks, for it is a truism of history that great civilisations have arisen not only where something more than the needs of existence could be satisfied, but where even those needs demanded creative thought: neither a frozen waste nor a lotus-eaters' paradise can produce a high culture. Moreover, that the sublimation of suppressed disharmonious impulses may result in genius is as much a part of modern theory as the better known conception that the suppression may lead to neurosis; the "predicaments" of Prof. Davis are the "conflicts" of the psychologists. The fall of civilisations has been ascribed to luxury and ease, but Prof. Davis takes the view that organisation, police and prohibition, and the like, abolish predicaments, and thus cut off the growth of culture. He regards this spontaneous degradation as inevitable, and makes the philosophical admission that to urge against the suicide of culture would be anarchy. But the abundance of individual neurotic manifestations under modern culture, even if they are sometimes replaced by those of genius, is a mark of the abundance of conflict, or predicament; and those who fear the collapse of European culture will scarcely admit that lack of predicaments is an element in the situation. Why civilisations fall is an enticing speculation. If Prof. Davis is right, and culture comes to an end by the efficiency of its organisation, then we may find comfort and security in a survey of world politics. But perhaps Prof. Davis has not really solved what is the greatest problem in history.

AN EXPERIMENTAL STUDY OF THE CIRCULATORY FAILURE IN PERITONITIS.

For many years it has generally been assumed that heart failure in peritonitis is due to the action of toxins, absorbed from the abdominal cavity, on the vaso-motor centre. The work on which this view was based was chiefly that of Romberg, Pässler, and Heineke, whose publications appeared in 1899 and 1900. For some years physiologists have been sceptical as to the soundness of this view, and a recent experimental study, carried out at the Karolinska Institute in Stockholm by Dr. Herbert Olivecrona,[1] has justified this scepticism. Working with rabbits, cats, and dogs, in which peritonitis was induced, he investigated the plasma and blood volume by the vital red method, using vital red obtained from the British Medical Research Council. A known quantity of the dye was injected intravenously, and after a certain interval the concentration of the dye in the plasma was estimated with the help of the Dubosq colorimeter. The burden of the thesis is that the vaso-motor centre retains its activity even under the most adverse circumstances almost to the time of death, and in the vast majority of cases the blood pressure remains normal during the earlier stages. But early in the disease, and long before there is any serious fall of the blood pressure or decrease in the vaso-motor reflexes, there is a reduction of the volume of the blood, and this reduction is progressive and considerable. From these and other observations it is concluded that this progressive loss of blood from the effective circulation must be an important factor in bringing about the circulatory disturbances in peritonitis. As in the case of secondary traumatic shock, it is probable that the reduction of the blood volume is due to dilatation and increased permeability of the capillaries, with stagnation of blood in the dilated capillary areas, and filtration of plasma through the injured capillary walls. Dr. Olivecrona's review of the methods at present practised in combating the circulatory disturbances in peritonitis is the reverse of laudatory. The administration of vaso-constrictor drugs is, he thinks, useless, if not actually harmful. If, as is very probably the case, the arteries in peritonitis are already constricted in order to compensate for the reduced blood volume, further vaso-constriction by such drugs as adrenalin may cause a decreased supply of blood to the tissues, and thus promote asphyxia. As Lamson and Roca have shown, the addition of adrenalin to a saline solution injected intravenously greatly accelerates its elimination from the blood-stream. There is little point in such intravenous injections of saline solution, for it leaves the circulation rapidly, and merely clogs the organism, giving rise to œdema and pulmonary complications. The intravenous injection of solutions of colloids, such as gum acacia, is also of doubtful value, and at present the transfusion of blood seems the most rational treatment of the circulatory disturbances in peritonitis.

THE DISTRIBUTION OF TRYPANOSOMES.

Trypanosoma rhodesiense, originally described in 1910 by Stephens and Fantham as a species distinct from *T. gambiense*, is the cause of a peculiarly virulent form of sleeping sickness in Nyasaland, Tanganyika Territory, Northern Rhodesia, and Portuguese East Africa. Not only are the clinical manifestations produced by this parasite more severe than are *T. gambiense* infections, but also it is subserved as an intermediary host by *Glossina morsitans*, the tsetse which ordinarily preys upon the big game. Up till recently, as stated, the parasite was regarded as having a peculiarly restricted Central African distribution, but now, as a result of an important communication by Dr. R. G. Archibald, director of the Wellcome Tropical Research Laboratories in Khartoum, our views on this matter will have to undergo considerable alteration, for, as reported by him in the *Annals of Tropical Medicine and Parasitology* (vol. xvi., No. 3), three cases of *T. rhodesiense* infection have been discovered in the Bahr-el-Ghazal Province of the Sudan. In this region both *Glossina morsitans* and *G. fuscipes* are abundant, and more especially in Tembura, the particular district in which the cases occurred. Inoculation into gerbils of the gland juice procured by aspiration from one of these men caused an intense infection, of which quite a large proportion represented the posterior nucleated forms so characteristic of the Rhodesian parasite.

THE PINK DISEASE.

ACCORDING to Dr. John Zahorsky,[1] who records four illustrative cases in children, aged from 15 months to 6 years, the affection variously designated as "the pink disease," "erythrœdema," or "acrodynia" has been known in Australia for a quarter of a century, but it was not until 1914 that the first description of it was given by H. Swift, of Adelaide, in a paper read before the Tenth Australasian Medical Congress. Clubbe, of Sydney, and other Australian physicians spoke of it as "the pink disease," a term which Dr. Zahorsky urges should be used until the pathology of the condition is better understood. The most extensive report of the disease was made in 1921 by A. J. Wood, of Melbourne, who, in a paper which received notice in THE LANCET,[2] collected records of 91 cases. In the United States the disease has been described by several pædiatrists, including Dr. Zahorsky himself, who at first mistook it for pellagra. In this country the only cases which have hitherto been reported are those by Parkes Weber and Thursfield and Paterson.[3] As a rule an eruption, which may resemble eczema, erythema multiforme, scarlet fever, rubella, urticaria or impetigo, appears to be the first symptom. In other cases the first striking symptom is a change in the child's disposition, which is shown by loss of appetite, insomnia, feverishness, and irritability. The typical rash is not unlike that of miliaria, consisting of minute papules surrounded by a narrow areola. It occurs profusely on the trunk and is less marked on the extremities. Erythematous patches are sometimes seen on the cheeks as well as on the loins, buttocks, thighs, arms, and neck. The miliaria may be associated with a marked redness of the whole integument and so be readily mistaken for the punctate rash of scarlet fever. An intolerable itching of the skin is generally present, and has led to the diagnosis of scabies. Excessive perspiration is the rule. The changes in the hands and feet which gave rise to the appellation used by Snowball of "raw beef hands and feet" form a characteristic feature of the disease. The palmar and dorsal surfaces are bluish red and swollen, and in severe cases icy cold to the touch. Some desquamation is often present. In addition to obstinate anorexia, disturbance of the alimentary system is shown by congestion of the alveolar and buccal mucous membrane, softening of the gums and loosening of the teeth, occasional vomiting, and diarrhœa. The patients appear to be very susceptible to respiratory infections. Three of Dr. Zahorsky's cases developed typical lobar pneumonia. Apart from the psychical changes already mentioned, affection of the nervous system is shown by paræsthesia, which is present in most of the cases, hyperæsthesia, and an initial increase followed by abolition of the deep reflexes. In all severe cases a hyperleucocytosis (from 12,000 to 30,000) is the rule; the differential count varies considerably in different cases. Polycythæmia has been recorded in some cases, including two of those seen by Dr. Zahorsky, who also found an increase in the viscosity of the blood at the height of the disease.

VACCINAL IMMUNITY.

THE intricate mechanism of immunity is of particular interest in the case of variola and vaccinia. A lecture recently given by Dr. H. A. Gins at the Robert Koch Institute in Berlin, summarised on p. 99, sets out some of the points which are specially interesting German workers. With several of these we are already familiar—e.g., it is well known that the higher the immunity the more insignificant and circumscribed is the local vaccination reaction, and conversely, a lower immunity coincides with a more severe local and general reaction. The quality of the local revaccination is an index of the degree of immunity possessed by the individual. The practical deduction is that vaccination or revaccination during an epidemic will readily distinguish those individuals who are likely to develop small-pox; contacts of small-pox patients who have been revaccinated, and who are showing a definite reaction that they are not immune, are those who must be carefully watched for signs of developing small-pox. It is also well known that if an individual is vaccinated or revaccinated in the incubation period of the disease, he will either be prevented from showing symptoms of small-pox or will develop the disease in a mild form, according as to whether the operation was performed early or late in the incubation period. If carried out during the first few days he will probably show no evidences of the disease; if later, various degrees of severity of small-pox may appear, the accepted explanation being that the attenuated, quickly growing germs of vaccinia produce immunity earlier than the virulent, more slowly growing organisms of small-pox. It is a race in the blood between the two types of organism. Whether the epidermis plays so important a part in the production of small-pox immunity as Dr. Gins contends must be the subject of further investigation; it can hardly be accepted on the evidence submitted, and so far the results have not reached a stage of any great practical value. The shifting of the age-incidence of small-pox in an immunised population is well brought out in the Berlin figures shown in Table II. Similar figures were worked out for this country many years ago, indicating that small-pox from being a disease of children has now become a disease of adults. The figures of the recent Glasgow epidemic indicate that neglect of infant vaccination is causing the pendulum to swing slightly back again in the old direction, and children are now becoming more liable to attack and death. The discussion which followed on the delivery of Dr. Gins's paper revealed a number of practical questions on which opinion is still divided, but the tendency still further to increase the potency of the vaccine was condemned on the ground of the danger of severe reaction, and the consequent risk of bringing the operation of vaccination into disrepute.

DEATH CERTIFICATION WITHOUT INSPECTION.

Dr. W. H. Whitehouse, coroner for Greenwich, recently held an inquest upon the body of a man in whose case a certificate of the cause of death had been given by a medical man who had not seen the body. Commenting upon the law which permits this course, the coroner said: "It is a remarkable thing that a medical practitioner may be called upon at any time, without seeing the body, to say that death was due to an observed disease, when violence or some other cause may have been responsible." He added that certainly the law governing death registration should be altered. Whenever, and if ever, the Act relating to coroners, which was passed in 1887, is amended or a new Act substituted for it, provision will no doubt be made for the medical man who certifies the cause of death only doing so after ascertaining by examination that death has taken place apparently from the causes which he certifies, and for which he has attended the deceased. It was so recommended by the departmental committee which reported fully in 1910 upon the law relating to coroners. Presumably, now that any change in the law will have to be made more than 12 years after the committee's report, a fresh committee will have to reconsider the findings of its predecessors, and will, perhaps, make fresh recommendations in view of later experience. The experiment, for example, of coroners sitting without juries has now been given a full trial in recent years, and no common or authoritative opinion on the subject has been elicited.

CALMETTE ON PASTEUR.

A special number of the *Bulletin* of the French Academy of Medicine reports the séance of Dec. 26th, 1922, which was given up to a celebration of the hundredth anniversary of the birth of Pasteur. Mr. A. Béhal, the President, opened with a biographical sketch, which was followed by estimates of Pasteur's work in relation to general biology, medicine, surgery, obstetrics, and veterinary medicine. Finally, Prof. A. Calmette, sub-director of the Institute, epitomised Pasteur's work in relation to the progress of hygiene. Without going further back than a bare half-century, it was possible, he said, to find the standard text-book of hygiene filled with such vague conceptions as temperaments, idiosyncrasies, habitudes and morbid *imminences*, and the frequent use of such terms as circumfusa, ingesta, excreta, applicata, percepta, and gesta. In the sixth edition of Michel-Lévy's authoritative handbook, published in 1879, no mention whatever appears of *maladies contagieuses*, nor of sanitary measures for avoiding them. At this epoch the magic of words still sufficed to satisfy the hygienic curiosity of the greater number of the medical profession. Prof. Calmette compared the mortality from transmissible diseases then and now, taking rabies and puerperal fever as examples. Before 1886 official statistics showed that for 100 persons bitten by rabid animals about 47 died of rabies, the mortality rising to 80 per cent. for those who had been bitten on the face. Now, from 1886 up to Jan. 1st, 1922, in the Pasteur Institute of Paris alone, out of 44,817 persons treated by Pasteur's method for prevention of rabies the total number of deaths was 150, or only 3 per thousand. In Berlin in 1864 puerperal fever carried off one mother in every 36 confinements; in London, from 1833 to 1865, the proportion was one to 34; in France, Tarnier reported in 1856 a childbirth mortality of one to 19, almost 6 per cent. "I saw," said Tarnier, "women enter the hospital in good health, full of life, and 24 or 48 hours later I was present at their death agony. It was a terrible spectacle!" Mortality in childbirth at this epoch was 17 times greater in hospitals than at home. Prof. Calmette recalled in this connexion the memorable séance of the Academy in 1879, when Hervieux was attempting to prove that puerperal fever at all events did not come within the germ theory, and Pasteur cried out, "Will the Academy permit me to sketch under its eyes the dangerous microbe to which I have been brought to attribute the existence of this fever." Now, as a result of antisepsis in maternity practice, the mortality at the Lariboisière fell to 0·39 per cent. by 1889, and at the Baudelocque Clinic, with the use of asepsis, sterilised gloves, and antistreptococcic serum, it had fallen below 0·05 per cent. Prof. Calmette concluded with a brief résumé of the effect of Pasteur's work on public hygiene. All that it is still customary to include under this word has been completely transformed by Pasteur's discoveries which introduced the idea of contagion. This idea was publicly announced for the first time in the British Public Health Act of 1875; it did not make its way officially into French sanitary law until Feb. 15th, 1902. "We can only regret," he said, "that Pasteur's own country was not the first to profit by the beneficent consequences of his work."

THE CENTENARY OF THE MEDICAL SOCIETY OF BRUSSELS.

The hundredth anniversary of the Société Royale des Sciences Médicales et Naturelles de Bruxelles was celebrated at a special meeting held on June 22nd, 1922, and the happy occasion has been further marked by the issue of a handsome "Volume Jubilaire." From an interesting account of the history of the society we learn that the first association of the kind in Brussels was the Société de Médecine, de Chirurgie et de Pharmacie, founded in 1795 when the revolution was in full swing. Internal dissensions led to the evaporation of this organisation, which was in 1804 replaced by the Société de Médecine de Bruxelles which did useful work until it, too, disappeared in the political turmoil of 1814–15. And it was not for several years that the Belgians could find leisure in their attempts to live peaceably in the United Kingdom of the Netherlands to replace it. Ultimately, however, on July 13th, 1822, the present society began its official existence which has done so much to promote the objects for which it stands. A glance through the summary history of its activities and the 54 papers which form the greater part of this jubilee volume emphasises the catholic breadth of its interests. Predominantly medical, the other natural sciences are always well represented. The first five papers, for example, deal with the anatomy of the pancreas in diabetes, multiple monstrous embryos in mollusca, the psycho-physiology of the fœtus and new-born infant, the action of quinidine in auricular fibrillation, creatine and creatinine in the blood. The members of the society evidently realise, as other medical men have done, that they will probably get the best progress if they cast their net widely and pick up from any and every department of natural knowledge pieces of information which are illuminating in their more professional applications. On such broad grounds the society has achieved great success; we wish it all good fortune in its continuance for another hundred years.

We regret to announce the death of Dr. Alfred Maxwell Williamson, medical officer of health for the city of Edinburgh.

The Hunterian Oration of the Royal College of Surgeons of England will be delivered by Sir John Bland-Sutton in the theatre of the College on Wednesday, Feb. 14th, at 4 p.m.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

II.

THE TREATMENT OF EARLY PULMONARY TUBERCULOSIS IN THE YOUNG ADULT.

THIS problem may, perhaps, be best approached by discussing a concrete case characteristic of thousands. A young man of the lower middle-class has hitherto been well and has just made a promising start in life, when he begins to lose weight and show other signs of failing health. Tubercle bacilli are found in his sputum. What should he be advised to do? All will often depend on the character of the advice given at this most critical stage in his career. He may follow one of three courses: 1. Go away for a change and live "the simple life" for some months in the country. 2. Go to a sanatorium. 3. Undergo treatment at home.

1. *The Simple Life.*—The risks of this course are enormous. Just at a time when the patient most needs skilled daily supervision he is deprived of even the limited curb of home life. He meets only able-bodied persons and is expected to live their life. Having nothing better to do, and knowing no better, he may go for long country walks, tragically ignorant of the harm of exercise unregulated by the clinical thermometer. He may, perchance, return home much better, *but he has not learnt his lesson.* So when he again breaks down, he is no wiser or better off than before.

2. *Sanatorium Treatment.*—The advantages of going at once to a sanatorium are innumerable. Many sanatoriums are not perfect, and quite unnecessary hardships are sometimes inflicted. But this is certain: the patient who has just developed pulmonary tuberculosis must completely revolutionise his life if he wants it to be long. He must be born again. Only in a well-conducted sanatorium is his re-birth feasible. He has to learn how to regulate every hour of his day, what to do and, above all, what not to do. In the sanatorium he learns from second- and third-stage patients how they came to this pass. Re-admission patients tell him the story of their relapse—how it might have been avoided. All this and much more he learns at the sanatorium. To expect him to acquire this knowledge from books and casual chats with his medical attendant is to expect the impossible. Never tell the patient that he will be cured by three months' sanatorium treatment. At the Mt. McGregor Sanatorium [1] (U.S.A.) for wage-earners, it was found that from one to seven years after discharge 90 per cent. of the patients in the incipient stage were fit for work. The average duration of treatment for patients in this stage was *seven* months. At Saugman's sanatorium [2] (Denmark), where patients stay as long as they wish, or as their means allow, over 90 per cent. of the first-stage patients were found to be fit for work three years after discharge. These successes were achieved because the two sanatoriums concerned were not handicapped by the "cure-in-three-months" fallacy.

3. *Home Treatment.*—Sometimes there is no alternative but treatment at home. The first essential to success is control of the temperature. Take it in the rectum. To order the patient's life and to graduate his exercise by the mouth temperature is often to court disaster. A rectal temperature of 98·2° F. or more on waking in the morning, or of 99·5° or more between 5 and 6 P.M. after an hour's rest in the horizontal position is abnormal and contra-indicates all exercise. Such a temperature points, as a rule, to complete rest in bed. See Dr. S. Vere Pearson on the temperature in phthisis.[3]

The Doctrine of Graduated Exercise.—The doctrine of graduated exercise owes its popularity to: (1) the vigorous and charming personality of its chief sponsor; (2) the primitive instincts of a race whose strength has never been to sit still; and (3) a minute kernel of truth. When the temperature is normal throughout the 24 hours, *carefully* graduated exercise is beneficial. But it is most difficult to graduate exercise and almost impossible to graduate the resultant auto-inoculation. It is probable that the doctrine of graduated exercise has done more harm than any so-called remedy—even more harm than tuberculin. The mortality is far greater from pulmonary than from surgical tuberculosis because auto-inoculation is far greater and more uncontrollable in the former. Yet, consumptives are set navvies' work, while the subjects of surgical tuberculosis are immobilised! The successes achieved by the silence treatment of tuberculosis of the larynx and by artificial pneumothorax and thoracoplastic operations have done much to prove that immobilisation is quite as essential to the tuberculous lung as to the tuberculous joint. Ungraduated rest, rather than graduated exercise, is the patient's first need when his disease is incipient and active.

Diet.—Do not stuff the patient. If mind and body are at rest, and there is little or no fever, he will eat all that is necessary, and if he is exhausted and feverish, forcing food on him will do little good. Milk in moderation is good, but at best it is a sloppy food to which many patients naturally object. Cod-liver oil is a useful supplement to food, especially in the winter; its vitamin content is approximately 200 times that of fresh butter. If the patient objects to the taste of cod-liver oil, give it in capsules, and remember that small doses over a long period are more beneficial than large doses, against which the system revolts after a week or two.

Specific Treatment.

Two enormous works, one in French,[4] the other in German,[5] have recently been published on specific treatment. They are a record of failures and deadlocks. Some day, no doubt, a master-mind will disentangle this twisted skein of research and give us a clear therapeutic lead. But at present we are far more embarrassed than benefited by the prodigious output of new vaccines, serums, and chemo-therapeutic remedies. Some are harmful, others harmless, apart from their exorbitant cost. None is of any proven specific value. But the few specific remedies which are harmless and not too costly, and which are administered by injection, do possess two very real merits. They act by suggestion and enable the physician to keep in constant touch with, and control of, the patient, who would otherwise drift away, neglecting the measures which, though of prime importance, he is apt to imagine are merely supplementary to the injections. A useful treatment of this kind is that recently advocated by Dr. E. E. Prest.[6] Possibly it may have other virtues than the two just mentioned.

[4] L'Infection bacillaire et la tuberculose chez l'homme et chez les animaux. By A. Calmette. Second edition. 1922. Paris: Masson et Cie. Pp. 644. Fr.50.

[5] Lehrbuch der Spezifischen Diagnostik und Therapie der Tuberkulose. By Dr. Bandelier and Prof. Roepke. 1922. Leipzig: Curt Kabitzsch. Pp. 631.

Cough.—If all coughing could be prevented, pulmonary tuberculosis would cease to be the fatal disease it often is. The text-books contain dozens of prescriptions for cough-mixtures, but often omit the most important point that many, if not most, coughs can be aborted by an effort of will. Coughing is like drink: the more you indulge in it, the more you want. The unrepeated cough is rare. Teach the patient that every cough is a nail in his coffin. Once, during a concert given at a sanatorium, the only members of the large audience who coughed incessantly were two non-tuberculous persons. The third-stage patient who has learnt to control his cough is often in the position to attend the obsequies of the ex-first-stage patient who barks incessantly.

Night-sweats.—They are rare in a sanatorium, and reflect adversely, as a rule, on the physician's management of a case. They are due to excessive auto-inoculation by day, or to inadequate ventilation and too warm clothing at night. Both causes can be eliminated. There are scores of prescriptions for night-sweats. Doubtless atropine and other drugs may suppress or reduce them. But the sweats are a salutary warning, and merely to suppress them with drugs is like boxing the ears of the small boy who truthfully cries that your house is on fire.

Hæmoptysis.—Shun opium and its derivatives, which, though useful in pleurisy, are mischievous in hæmoptysis. Not one hæmoptysis in a hundred is directly fatal from the mechanical effects of loss of blood. But many a hæmoptysis is the starting-point of a serious and rapid extension of the disease due to stagnation of effused blood in the lungs. Such stagnation is greatly facilitated by opium, the conventional ice-bag, and by keeping the patient absolutely quiet in bed. Keep him in bed certainly, but let him sit up and change his position whenever he likes. The recent work of S. Bang[7] has shown that hæmoptysis is remarkably independent of the patient's movements. The most effective hæmostatic has been shown by the investigations of H. Elving[8] to be calcium chloride, 20 c.cm. of a 15 per cent. solution injected into a vein rapidly increasing the rate of coagulation of the blood. A more simple procedure is to give 5 to 15 g. of sodium chloride by the mouth; as von den Velden[9] has shown, sodium chloride thus given increases the rate of coagulation in five minutes. When the patient is very nervous 3 g. of sodium bromide may be substituted for the sodium chloride; remind the patient that "bleeders do best."

Miscellaneous Hints.

Teach the patient to go to bed whenever he catches a cold, and to remain there till it is over. It may then last only a few days. Otherwise it may last for months, stirring into renewed activity lesions which had "healed." The non-tuberculous person can, unfortunately, afford to go about with a cold, coughing, sneezing, and spluttering. The consumptive cannot. Encourage him to take a whole or half day off in bed every Sunday and always to rest for 30 to 60 minutes before each meal. Never send him to a consultant who has recently identified himself with some new cure-you-while-you-wait "stunt." There is at present no short cut to recovery. For an excellent account of home hydrotherapy consult Sir James Kingston Fowler's "Pulmonary Tuberculosis" (pp. 202 and 203), and for the general management of the case Dr. F. Rufenacht Walters's "Domiciliary Treatment of Tuberculosis." Good books for the patient to read are Dr. Lawrason Brown's "Rules for Recovery from Tuberculosis," and Dr. Noel D. Bardswell's "Advice to Consumptives."

COÖRDINATION OF HEALTH WORK IN AMERICA.

BY WALTER CLARKE,
ADMINISTRATIVE SECRETARY, NATIONAL HEALTH COUNCIL, NEW YORK.

Antecedents and Membership of the National Health Council.

THE history of the National Health Council stretches back over a period of 12 or 15 years, during which the need for coöperation and coördination among national health agencies was seen more and more clearly throughout the United States. Especially important was a conference of 39 health agencies held in April, 1913, at New York, at the suggestion of the Council on Health and Public Instruction of the American Medical Association; this conference resulted in the appointment of Prof. Selskar M. Gunn to study the problems of coördination among national health agencies. His report, completed in May, 1915, showed that 24 national organisations, of which 10 were of greater importance, were engaged in health activities. A continuation committee took up the intensive study of these organisations for the purpose of developing a national clearing-house for voluntary health work, but these developments were interrupted temporarily by the war, and were only taken up again in the winter of 1918–19, when a conference was called by the American Public Health Association. Further study was then found to be necessary, and in the summer of 1920 a special committee was formed for this purpose, and Dr. Donald B. Armstrong was engaged to make a survey of the existing situation, the work being financed by the American Red Cross. His report was presented to a conference which met in Washington in October, 1920. After discussion of the report by this and a subsequent conference the National Health Council was at last formally organised in December, 1920.

The 14 organisations which are direct, indirect, or conference members of the National Health Council cover the major fields of public health work in America. The general American public is perhaps best represented by the American Red Cross, the professional health worker by the American Public Health Association and the Conference of State and Provincial Health Authorities of North America, the medical profession by the Council on Health and Public Instruction of the A.M.A., the public health nurse by the National Organisation for Public Health Nursing, and the National Government by the United States Public Health Service, which is a "conference member" of the Council. The National Child Health Council represents a group of child welfare organisations, and the National Committee for Mental Hygiene, the American Social Hygiene Association, the National Tuberculosis Association, and the American Society for the Control of Cancer are also members of the National Health Council. The financial support of the Council has been derived from several sources, but especially from the American Red Cross and certain foundations. Dues of members, payments for services rendered by the Council to members, and the sale of publications issued by the Council are further sources of revenue.

Purposes and Organisation.

The Council exists to promote mutual understanding and helpfulness among American health agencies and to aid them in their work by conducting a central service bureau. The fundamental spirit of the Council is exemplified, and its practical operation is made more feasible, by the close association of members in a joint office arrangement. Seven of the associations and committees, coöperating through the common service committee of the Council, have established joint offices in the Penn Terminal Building in New York. By this arrangement the directors and staff of the several agencies having headquarters in New York are in daily contact with each other. This close association is increased by the organisation under the Council's business committee of inter-staff conference groups appointed to advise members on their activities, under the following heads: nursing coördination, publicity and education, publications, and health plays, exhibits, and films. There are also standing committees to promote efficiency in the service and to safeguard the health and welfare of employees. Two special committees on "health days" have been appointed to prepare plans for a national campaign in which health examinations will be emphasised. The secretariat of the Council coördinates and, so far as possible, gives effect to the work of these inter-staff committees. The Council itself, as distinguished from the groups of staff members, is composed of one representative and one "alternate" from each member agency. This small group of official delegates govern the Council and determine all matters of policy, but the Council has delegated authority for the execution of policy to a group of five representatives called the business committee, to a committee on membership, and to a common service committee. The organisation of the Council is kept as simple as possible, and its secretariat is maintained on inexpensive and modest lines.

Achievements of the Council.

The functions of the Council are best indicated by a brief summary of its current activities and achievements since the foundation. The work is carried on in two offices—viz., the official headquarters in Washington and the joint offices in New York. Through the Washington office, for which a room is generously provided by the American Red Cross, the Council's representative has been in close contact with those government bureaux which deal in any way with health, and with the American Red Cross and the National Child Health Council. At the New York office are carried on those services which require association with the largest number of national voluntary health and welfare agencies. The following is a brief résumé of the work of the Council in both offices.

1. *Publications.*—(*a*) Establishment and maintenance of the federal health legislative information service, including a bulletin; (*b*) maintenance of the State health legislative information service in coöperation with the United States Public Health Service, also including a bulletin; (*c*) issue of the "Monthly Digest," a general information publication; (*d*) issue of the "Library Index," listing important current health publications; (*e*) issue of list of 300 health films; (*f*) issue of the "Weekly Common Service News," a "house organ" for the staffs of members.

2. *Special Washington Activities.*—(*a*) Publication of a series of authoritative reports and an organisation chart dealing with the health activities of various government bureaux; (*b*) coöperation in development of plans now being carried out for a permanent health exhibition at the Smithsonian Institute in Washington; (*c*) general headquarters service for members (personal representation, arrangement of conferences, collection of information, &c.); (*d*) consultative assistance for the American Red Cross health service.

3. *Common Service Committee Activities.*—(*a*) Joint office projects for certain member and tenant organisations, including renting, leasing, janitor service, &c.; (*b*) accounting, library, purchasing, mimeographing and copying, shipping, storage, telephone exchange, film distribution, &c.; (*c*) direction of work of inter-staff conference groups; (*d*) establishment of a health examination system for staffs of members; (*e*) confidential study of salary standards and methods among organisations in New York joint offices; (*f*) office administrative studies.

4. *Additional Information Service.*—General clearing-house of information regarding health organisations and health work, &c.

5. *National Coördination Work.*—Arrangement of lectures for staffs of members and for outside agencies, study of health plays, assembling of exhibition materials, and arrangement of exhibitions, inquiry into problems of production and distribution of health motion pictures, &c., and establishment of a statistical service, and of various committees to consider problems of public health nursing, negro health interests, national health days, &c.

6. *Field and State Coördination Work.*—Preparation of special reports on public health subjects for various associations, and study of coördination of health activities in several States.

7. *Miscellaneous Services.*—(*a*) Organisation of health institute in connexion with semi-centennial of the American Public Health Association; (*b*) coöperation in Rotary Health Week with members, particularly with the National Tuberculosis Association; (*c*) coöperation in Cancer Week activities, 1921 and 1922; (*d*) numerous minor activities.

Programme for 1923.

The programme for the year 1923 involves, in the main, a continuation of activities already under way, together with attention to their improvement. It will be understood that, during the experimental years of the National Health Council, all activities are subject to constant critical study. Those which prove to be useful to members and to their enterprises may be elaborated, the resources of the Council permitting. Others will be discontinued and new services will be established as rapidly as clearly-defined needs appear.

THE RAINFALL OF 1921 AND 1922.[1]

TOWARDS the close of 1922 the Meteorological Office (Air Ministry) issued their report on British rainfall for 1921. No one who has studied the report will regret or wonder at its somewhat belated appearance; it contains a mine of clearly stated information about the most remarkable meteorological year on record. It is probably to this fact, rather than to the mere data of total rainfall, that we must look in considering the economic effects of a dry period like that of 1921. The great bulk of the water used for domestic and industrial purposes in the south-east of England has percolated into the porous rocks many months before it is utilised, and the effects of so disastrous a drought must, therefore, inevitably continue long after its termination, since subsequent heavy rains must be required to help to restore the subsoil water level. These facts are worthy of the earnest consideration of water authorities.

Rainfall, 1921.

The deficiency of rainfall in the south-east of England was so great that the replenishment of underground sources of water was practically entirely suspended. The report states that as regards evaporation, taking, as an example, Camden-square, London, where observations have been continued since 1885, the remarkable figure of 19·69 instead of an average (1885–1919) of 15·5 (+4·19) in. is recorded. Thus the amount of evaporation exceeded the average by 4·19 in. and was for the first time on record actually larger than the total rainfall. It is true that in 1906 and 1911 somewhat comparable figures (19·03 and 19·53 respectively) were obtained, but these were phenomenally warm years of about average rainfall. It is somewhat doubtful whether records of observations of percolation and evaporation represent the actual facts with the same precision as those of rainfall, but they can be accepted as giving some evidence of the conditions which prevailed. During 1921 there were areas in Essex, Kent, and the Fen District where the number of rain days (0·01 in. or more of rain per day) was actually less than 100; the ordinary qualifications (such as "weather permitting") almost ceased to be used over a large portion of the British Isles, and open-air engagements were generally made without any reference to such contingencies as rainfall. The deficiency in rain days for the whole of the British Isles was not nearly so remarkable, but this was due to contributions from areas outside the south-east of England where normal, or less abnormal, conditions prevailed. The distribution of wet days (0·04 in. or more of rain per day) was somewhat similar to that of rain days and to total deficiency of rainfall; the south-east of England had less than 75 wet days, and for the whole of England and Wales the number was only 110, as compared with 151 in 1920 and 143 in 1919. On the average, 64 absolute droughts (15 or more consecutive absolute non-rain days) and 52 partial droughts (29 or more consecutive non-rain days, not absolute but judged by mean rainfall) occur annually at 100 recording stations. In 1921 the figures were 86 and 109, indicating that there were more long *rather* dry periods than short *very* dry periods. As regards dry spells (15 or more consecutive non-wet days) at 100 stations the figures for 1919, 1920, and 1921 were 98, 56, and 201 respectively. The definitions given, useful as they are, do not reveal the main characteristic of 1921, which was the persistence of deficient rainfall to a degree hitherto unsurpassed. The dates of droughts in 1921 at Camden-square and Tenterden are shown in Table I.

---

The number of rain spells (15 or more consecutive rain days) and wet spells (15 or more consecutive wet days) was above the average for the British Isles, but this apparently paradoxical result was largely due to the excessive rainfall in the wettest portions of Scotland. In England the rain and wet spells were abnormally small in number. At Camden-square the total duration of rainfall was only 269·2 hours, or 167·7 below the average of 436·9 (1881–1915). Only once previously (1898) has the number of hours fallen so low as 300.

In some respects the most interesting of these occurrences was that affecting the area of drought. On Sept. 11th, a strip of the south of England, extending from the Thames estuary to the Bristol Channel, received welcome relief from the prolonged and serious drought. The general rainfall over an area of 12,210 square miles was 1·42 in. In England and Wales, as a whole, only two months, January and August, exceeded their averages, and during the remaining ten months the deficiencies rose, in February and June, to 85 and 82 per cent. respectively. The monthly figures for Camden-square read in sequence, as follows: 2·48, 0·19, 1·19, 1·29, 1·03, 0·37, 0·13, 1·65 2·50, 0·63, 2·01, 1·13 in., total 14·60 in. (average 1881–1915, 24·47 in.).

Total Rainfall, 1921, in Relation to the Average.—Over 50 years of complete study, and about 100 years of less comprehensive study, of the distribution of annual rainfall over the British Isles justified meteorologists in drawing certain conclusions. One was that, whatever the rainfall for a particular place might be, it was fairly safe to assume that there the rainfall would not fall appreciably below 60 per cent. of its average in the driest of years. Over a very large area in the south-east of England this limit of 60 per cent. of the average (or 40 per cent. deficiency) was in 1921 exceeded; in these districts the rainfall was probably the smallest for at least a century and a half. In parts of Kent the year's rainfall was less than half the average amount. At Margate only 9·29 in. fell during the year. Over the greater portion of England 10–20 in. of rainfall sums up the position. On the west coast of Scotland a very different set of conditions prevailed, and at Kinlochquoich and Loan (Inverness-shire) the remarkable totals of 148·36 and 201·78 in. were recorded.

Pressure Conditions.—The rainfall of the British Isles is derived almost entirely from the south-westerly variable winds which blow across this country and carry with them large quantities of moisture from the Atlantic Ocean. The normal pressure distribution is represented by practically parallel isobars with a gradient from S.S.E. to N.N.W. The isobars over the north were fairly normal during 1921, but the pressure was decidedly high; towards the south the isobar of 1020 millibars followed the normal direction as far as the south of Ireland and then turned sharply to the S.S.W. This apparently caused a "fanning-out" of the prevailing winds over the south-east of the country. Divergent currents induce, according to expert meteorologists, a tendency to downward motion in the atmosphere, and descending currents give rise to dry conditions. Broadly, the drought was due to the abnormal displacement northward of the high pressure belt.

Other Features of the Drought.—The report states that in the south of England records of rainfall duration were in nearly every case the lowest ever recorded; the percentage deficiency of duration was approximately the same as that of the total fall, and the percentage deficiency of days with rain was of about the same magnitude as that of the total rainfall. These observations suggest that the drought of 1921 may be regarded as the result of rainfall being extremely infrequent, such rain as did fall being of about normal intensity. A large number of observers comment on the infrequency of thunderstorms, and it may be added that although a fair number of cyclonic rains occurred, cyclonic rains were certainly scarcer than usual and very few of them were of notable intensity.

Rainfall, 1922.

In considering the rainfall in 1922 (see Table II.) the drought of 1921 must be borne in mind; a year may stand for itself, to some extent, so far as surface waters are concerned; but with regard to underground water the case is very different. The wet years preceding 1921 were probably, in their cumulative effect, a reserve force of considerable power. The year 1922 opened very well, the gain at the end of February being 1·48 in., reduced in March to 1·16 in., rising in April to 2·64 in. May and June were disappointing, the gain falling to 0·81 in., but at the end of September the gain was 2·92 in. Nevertheless, it must always be remembered that the rainfall in late spring, in summer, and in early autumn is largely discounted by evaporation, luxuriant growth of vegetation, &c. October and November were most disappointing. These, with the months of December, January, and February have a dominating influence on water-supply. By the end of November the gain of 2·92 in. in September had fallen to the meagre figure of 0·38 in. Approximately, the first two-thirds of December fell far short of expectations, but the Christmas season was so far satisfactory that the rainfall for the year 1922 (25·60 in.) exceeded the average by 1·13 in., and January, 1923, starts under favourable auspices.

Combined Rainfall, 1921–22.

The position for the 24 months ended Dec. 31st, 1922, is not altogether satisfactory. For the period in question the deficiency (Camden-square) amounts to 8·74 in., and as our hopes were previously based on 1922, so must we now look to 1923 for a restoration of the balance. In 1922 there was a pretty general feeling that the wet summer had more than compensated for the drought of 1921, but this view will not withstand the acid test of expert experience. In effect, the drought of 1921 still persists, hardly mellowed by the experiences of 1922, and almost entirely dependent on 1923 for a restoration of the normal balance. The position is not disquieting, but it affords no grounds for jubilation from a waterworks, or perhaps from any other point of view.

VACCINAL IMMUNITY:

RECENT GERMAN WORK.

IN a lecture recently given at the Robert Koch Institute for Infectious Diseases in Berlin, Dr. H. A. Gins[1] sketched the gradual growth of our knowledge of a subject which is even now but very imperfectly understood. It has been known for a long time that a true small-pox epidemic occurs only in man and in sheep, the disease in cattle, goats, and pigs giving rise only to a localised process, the virus from which is not particularly infective. The experiments of the earliest vaccinators, Jenner, the Italian Sacco—who was the first to discover the principle of allergic reaction—Pearson, and others established the fact that an attack of either kind of small-pox is capable of giving protection against its own or any other variety, and, further, that an animal-pox is probably in close biological and ætiological relationship with small-pox epidemics in man—hence the practically simultaneous disappearance of ovinia (sheep-pox) and small-pox from Germany.

Nature of the Protective Substances.

The practical result of these discoveries is to be seen in Jugo-Slavia at the present time, where the protective inoculation of sheep has been successfully practised with highly virulent non-glycerinated vaccine on principles laid down by the speaker. The French authors, Bridré and Donatien, who were unsuccessful in similar experiments, worked with a different technique and with a much less virulent vaccine. The discovery of specific changes in the blood serum in epidemic diseases, which was contemporaneous with the evolution of bacteriology, led to the search for specific substances in the blood both of small-pox patients and of experimental animals, but although the resulting researches led to a variety of interesting results they have hitherto not yielded any points in the serological differential diagnosis between small-pox and varicella. Precipitin was first discovered by Tanaka in 1903, but in spite of the confirmation of his discovery by several writers it has led to no important results, the same being true of Sato's new test with the serum of vaccinated rabbits. Complement-fixation substances in small-pox and vaccinia have been exhaustively studied by several writers, but hitherto have for various reasons been found of little practical value. Of greater importance are the anti-virulent substances in the blood in small-pox and vaccinia, which were first discovered by Hlava and Honl in 1895, and which since then by means of an improved technique have been found by Gins and by Sato to be constantly present in the serum of vaccinated rabbits. In the serum of convalescents from small-pox both Gastinel and Gins have found the same substances, but not, at least so far as the experience of the latter observer is concerned, with such absolute constancy as to serve as a method of diagnosis. Fujii has also quite recently found these bodies in the blood of vaccinated and revaccinated people.

These results have shown beyond a shadow of doubt that we are here dealing with substances that have a definite value as an expression of immunity, or at least bear some relation to it. Their disappearance from the blood does not necessarily coincide with loss of immunity either in experimental animals or in man, in whom they are frequently lost while an undoubted immunity still persists. They are therefore probably to be looked upon as the sign of a newly-acquired immunity, and as such are of definite clinical value. The great point of Gins's paper is, however, the value he attaches to the function of the epidermis as the most important element in the production of small-pox immunity, in proof of which he adduces the suggestive fact of the non-appearance of the inoculation pustule in immune individuals after cutaneous inoculation of the virus.

The Site of Immunity.

After a general survey of vaccinal immunity in experimental animals, in which he gives grounds for believing that the horny layer of the skin invariably takes some part in the process, Gins points out that the key to the problem lies in the researches of Pirquet and others, who have demonstrated the fact that the convalescent small-pox patient and the vaccinated individual react to revaccination in a different manner from other people; so much so, that we can to-day take for granted that the higher the immunity the more insignificant and circumscribed is the local reaction, and, conversely, the greater the susceptibility the more severe are the local and general reactions. He notes by the way that although absolute immunity is to be met with it is rare, any immunity being as a rule capable of being broken through by exceptionally virulent material. By the trifling degrees of revaccination reaction the virus is shown to be quickly destroyed, and only in cases of the more severe local and general reactions an augmentation [Vermehrung] of virus takes place at the site of inoculation. It is easy to understand that in these latter circumstances a reinforcement of immunity is obtained, owing to the considerable amount of virus in the circulation which is producing antigen. Sato, in recent experiments on immunised rabbits, concluded that in revaccination an increased immunity is attained without any increase of virus at the site of inoculation, but Gins considered his technique to be in fault, and reiterates his conviction that immunity can only be raised where there is such a local increase. On epidemiological grounds Paul and Jürgens came to the same conclusion. In every small-pox epidemic individuals are found who shortly after a successful vaccination contract varioloid. In every such case in which Dr. Gins had been able to ascertain the nature of the revaccination reaction he found it to have been either papular or vesicular [Knötchen- oder Bläschenreaktion], and comments on the peculiar property thus attaching to immunity:—Vaccinal immunity is capable of destroying vaccinia virus introduced into the epithelium, but cannot prevent virulent infection with true small-pox virus. The practical bearing of all this Dr. Gins shows to be the fact that from the quality of the local revaccination appearances the degree of immunity present can be ascertained. Revaccination will enable immune individuals to be recognised and will immunise afresh those who are no longer immune.

---

[1] Med. Klinik, Nov. 19th, 1922.

Immunity and Age-Incidence.

If the kind of reaction be taken into account in revaccination striking differences will be found in the different age-groups, as will be seen in Table I., in which the influence of revaccination on the raising of immunity is unmistakable, as is also the increase of defectively immunised individuals after the age of 36.

TABLE I.

Age-group.	Vaccinations.	Fully developed pustular reaction.	Percentage giving pustular reaction.
12th year.	1435	321	22·3
12th–20th year.	794	108	13·6
21st–25th ,,	818	155	18·9
26th–30th ,,	613	139	22·6
31st–35th ,,	465	135	29·03
36th–40th ,,	386	190	49·2
Over 40	1238	768	62·04

Dr. Gins believes that a similar estimation of the proportion of badly protected individuals in the general population has never before been undertaken. He also gives an instructive table (II.) showing the death-rate from small-pox in Berlin in the different age-groups at three different periods.

TABLE II.

—	1758–74	1870–72	1916–17
Percentage of deaths over 40 years .	0·07	25·85	90·56
,, ,, between 39 and 12	1·25	27·13	7·32
,, ,, under 12	98·7	49·02	2·12

The influence of a general immunity will thus be seen to be demonstrated by a complete reversal of the figures. From being a disease of children small-pox has become definitely a disease of adults, this alteration in the character of an infectious illness having been effected purely by a systematic active immunisation.

Dr. Gins made no claim in his paper fully to have cleared up the disputed questions connected with small-pox immunity, but merely to have helped in their solution by pointing out that neither laboratory work, nor statistics, nor epidemiology can separately lead to any conclusive results, a critical utilisation of all these methods of investigation with the same object in view being indispensable.

VITAL STATISTICS OF SCOTLAND, 1921.

THE relatively prompt issue of the Sixty-seventh Annual Report of the Registrar-General for Scotland, dealing with the vital statistics of the year 1921, even though its price is marked as 10*s*. 6*d*., gives a feeling of satisfaction which contrasts with the feelings beginning to be entertained anent the inordinate delay in the issue of the English Registrar-General's reports. Why is this? But as Kipling has it, that is another story.

The present Scottish report, although not so exhaustive as the English report—the medical comments in which are a mine of invaluable information—contains matter of great interest to physician and statistician alike.

Births.—The birth-rate was 25·2 per 1000, which is slightly lower than the birth-rate in the antebellum years. But the death-rate being only 13·6, there is still a rate of natural increase of 11·7 per 1000, which leaves a satisfactory margin for that invasion of other parts of the world by competent and indispensable Scottish leaders in the various calls of life.

Deaths.—The infant death-rate was 90·3 per 1000 births, as compared with 92·0 in the preceding year. A study of the relative infant mortality in different parts of Great Britain and Ireland shows that the course of events for a considerable series of years has run almost parallel in Scotland and in Ireland, but that in the last few years the rate of infant mortality has fallen at a considerably greater rate in Scotland than in Ireland. England's infant death-rate has parted company with its Scottish and Irish neighbours, and has declined to an extent which differentiates England's experience most markedly. Why is this? Meteorological differences are not likely to be competent to account for this difference; and there can be little hesitation in falling back on the wider spread and more successful child welfare work which during the present century has been carried out in England.

Tuberculosis.—A few years ago Prof. Pearson in *Biometrika* suggested the likelihood that the decrease in the rate of decline of the death-rate from phthisis in England might even be followed by a cessation of this decline or an increase in the phthisis death-rate. English experience falsifies this forecast; and the Scottish figures point in the same direction as the English. The Scottish death-rate from phthisis in 1871–80 averaged 244 per 100,000; in 1881–90 it had become 202; in 1891–1900 the rate was 171, in the next decade 139, and in 1911–20 it was 105, reaching the remarkably low figure of 81 in 1921. Table 40, from which the above figures are extracted, does not separate the sexes, and this is unfortunate in view of the disturbing influence of war on sex proportions; but it is remarkable that the Scottish figures for phthisis in both sexes together fail to show the great temporary increase in death-rate which occurred in England. The terrible figures of phthisis mortality in certain areas—e.g., 230 in Lerwick, 217 in Invergordon, although occurring in small populations, call for exhaustive inquiry and remedial measures.

Cancer.—Next to tuberculosis, cancer is the most important single disease dealt with by the Registrar-General; for pneumonia is a complex of diseases, and even then only caused in 1921 a death-rate of 110 per 100,000, as compared with 122 from cancer. The registered death-rate from cancer has increased more than threefold since 1861. The sites of fatal cancer are given in a separate table. Among males and females alike cancer of the stomach heads the list. Cancer of intestines comes next in men, and so in women also, but cancer of the breast and of the uterus cause an almost equal number of deaths, without any corresponding mortality of moment in men. There is a great excess of cancer in the upper digestive tract of males. In cancer of lip (6 times), of mouth (4 times), of tongue (nearly 11 times), of jaw (4 times), and of pharynx, 2½ times as many deaths occur in men as in women. The corresponding English figures raise the problem as to whether cancer of some parts of the body is not increasing, while that of other parts is not. Furthermore, to what factors are we to ascribe this excessive proneness to cancer of certain tracts in man? Is it tobacco, or secondary effects of syphilis, or the local irritating effect of strong alcoholic drinks, or all of these in varying proportions? The answer cannot be given with any confidence. If tobacco-smoking becomes much more general in women, there may occur an approach to a check experiment, so far as tobacco is concerned.

Many other subjects of interest are dealt with in this report, but we need only refer to the very useful Appendix IV, giving the new international classification of causes of death of 1921, in parallel columns in comparison with the corresponding classification of 1911.

Correspondence.

"Audi alteram partem."

SMALL-POX AND AMAAS.

To the Editor of THE LANCET.

SIR,—In your issue of Oct. 14th last (p. 808) Dr. J. A. Mitchell proclaims me as the chief exponent of the "amaas, a separate and distinct disease" theory, giving as a reference my paper Amaas or Kafir Milk-pox (THE LANCET, 1904, i., 1273). I definitely decline responsibility for a view I have never held or expressed. Indeed, it seems remarkable that any responsible critic could read such an interpretation into the following passages which summarise my paper in THE LANCET to which Dr. Mitchell refers. After pointing out that amaas could not well be confounded with varioloid varicella and the infectious disease in Lascars, the article goes on to say—

> "When compared with variola such a definite statement cannot be made, for it will be seen that amaas resembles small-pox in many particulars, the differences which exist between these two diseases appear to consist more in degree of virulence than of kind. The provisional conclusion arrived at on the relationship of amaas to variola is that the former *is small-pox* mitigated by some undetermined factor or factors."

For the vindication of my personal view I would not trespass on your space, but as the whole subject is shrouded in confusion I may perhaps be allowed to assist in removing some of the obscurity attending it. To narrow the issue reference will be confined to a few of the more definite aspects of the subject.

In the present state of knowledge no one can affirm what the relationship between small-pox and amaas really is. It may be conjectured and held that the weight of evidence is in favour of their identity, or the converse view may be believed, but demonstrable proof either one way or the other is lacking and is probably hidden in the unknown ætiological agent of small-pox. The history of medicine shows conclusively the fallacy of assuming diseases to be identical until they have been traced to a single definite cause. That the death-rate of amaas is low compared to the mortality-rate of classical small-pox is practically certain. If we take the death-rate of amaas as set out in Dr. Mitchell's paper, Table I., it will be found to work out for white and black, unvaccinated and prevaccinated, of a total of 17,000 odd cases extending over a period of 13 years to be 3·73 per cent. This aspect has been endorsed by various authors in different parts of the world who have recorded their experiences of the disease under the term "alastrim" or other name. A second fact which appears to be certain is that Jennerian vaccination is a preventive measure for amaas as for small-pox.

The next question and one of great importance still remains to be decided. Does amaas breed true to type—that is, does it remain a fairly non-lethal disease or can it, for some unknown reason, become virulent small-pox? Table I. in Dr. Mitchell's paper above referred to on the whole lends colour to the view that for the greater portion of 13 years the disease was true to this low mortality type. It would also appear from the history of this disease endemic among the natives for generations who show no very great concern for it that in the main it is true to the low mortality type. Dr. J. C. McVail believes that the mild type may coexist side by side with a virulent type such as occurred in the provinces and London in 1902 and 1905 respectively.

With such a moderate amount of fact to substantiate its claim to a special term in nosology, it may well be asked whether it would not be wiser to confine ourselves to the term mild small-pox rather than employ a distinctive name like amaas, yet we cannot be sure that the virus of small-pox and amaas are identical and do not differ from one another in some respect. If we are not justified in assuming the identity of the virus in the two cases, neither can we deny the possibility of their being different. In the analysis of small-pox and amaas we are confronted by certain differences the sum and total of which, measured by the end-result—namely death—are widely different. As investigators of disease we are concerned with the reason why two such apparently similar diseases should have such different mortality-rates and the only feasible view would seem to be that there is more than one strain of variola virus.

On the whole the evidence, such as it is, seems to warrant the view that there is a variety of small-pox of a mild or mitigated type, nor does there appear to be any inherent improbability in such a surmise.

I am, Sir, yours faithfully,

Cape Town, Dec. 15th, 1922. W. E. DE KORTE.

CONGENITAL ABSENCE OF THE SPLEEN.

To the Editor of THE LANCET.

SIR,—The annotation in THE LANCET of Dec. 30th, 1922, on congenital absence of the spleen as being one of the rarest visceral anomalies, prompts me to report my notes upon the following case:—

Miss M., aged 24, previously healthy in every way, came over by train to visit some friends in York for the day on Sept. 1st, 1906, which was one of the hottest days recorded for several years—the thermometer registering 92° F. at midday. At 2.30 P.M., on getting up to say good-bye to her friends after a light meal, staggered and became unconscious. Seen half an hour later, she was clearly suffering from a cerebral hæmorrhage, and after the expiration of an hour breathing suddenly ceased, while the heart continued to beat for a few minutes till death ensued.

At a post-mortem made 28 hours after death, an extensive hæmorrhage into the fourth ventricle was discovered, breaking into both lateral ventricles and into the substance of the brain. No focus of hæmorrhage and no aneurysmal dilatations of the arteries of the brain could be discovered. The valves of the heart were perfectly healthy, as also were the lungs, liver, and kidneys, and there was no evidence of infarcts.

Beyond a very small accessory spleen, no spleen could be discovered in spite of a careful and detailed search. It appears a reasonable hypothesis that the absence of spleen, the abnormal heat, and the hæmorrhage at this unusual early age, stand in correlative association.—I am, Sir, yours faithfully,

G. A. AUDEN, M.D. Camb., F.R.C.P. Lond.,
School Medical Officer for Birmingham.

Jan. 3rd, 1923.

GASTRIC AND DUODENAL ULCER AS A FAMILIAL DISEASE.

To the Editor of THE LANCET.

SIR,—In connexion with Dr. A. F. Hurst's address in your issue of Dec. 30th on "Hypersthenic Gastric Diathesis," and his view of gastric and duodenal ulcer as a family disease, it might be interesting to record the fact that I have operated on—and definitely proved in consequence—four members of a family: father and son with duodenal ulcer, one perforated: daughter with gastric ulcer, and an uncle on the mother's side with duodenal ulcer. The mother had gastric ulcer operated on by another surgeon.

I am, Sir, yours faithfully,

Edinburgh, Jan. 5th, 1923. J. W. DOWDEN.

BACTERIOLOGY IN ANCIENT CHINA.

To the Editor of THE LANCET.

SIR,—In the last issue of THE LANCET (p. 38) the question was raised whether more than 1000 years ago the Chinese had knowledge of micro-organisms of disease, and it was justly remarked that many of our inventions and discoveries are found on inquiry to have been anticipated, wholly or in part, by the race possessing the oldest existing civilisation. With such examples as the mariner's compass, gunpowder, printing, and (according to an eminent sinologue) a flying-machine before our eyes, it is not surprising that readers of Mr. Werner's recent work[1] should speculate on the possibility of some bacteriological notions having existed in sixth-century China. Indeed, though investigation proves the surmise untenable so far as it is based on Mr. Werner's book, there are reasons, to be explained later, why it is less fantastic than it might at first sight appear.

The original source of Lü Yüeh's exploits in attempting to spread pestilence among his enemies is a long, popular romance, narrating many deeds of martial valour in which gods, demi-gods, fabulous mortals, and some known to history take part. It is entitled "*Fêng shên yen i*." Nothing certain is known of its author or date, but the edition of 1695 was probably the first printed. In dealing with myths of epidemics, Mr. Werner follows almost word for word Father Doré's abridged versions,[2] published in 1915, of several episodes taken from this romance. Unfortunately, he has failed to correct many of Father Doré's mistranslations, of which the sentence about "plague microbes" is one. Reference to the Chinese text[3] shows that the term used is *wên-i chung*, which means "pestilence bell"; and, indeed, there is in some editions a picture of Lü Yüeh holding in one of his six hands a bell of the kind used in magic and religious ritual to the present day. It is natural that the Western reader, without a specialised knowledge of things Chinese, should look for some evidence of the alleged "plague microbes" in the picture illustrating Mr. Werner's chapter on epidemics, and that he should have his expectations satisfied by finding there a number of strange comma-like or horseshoe-like objects floating in the air. But these are, in fact, merely examples of a pictorial convention denoting flames, such as has been practised by Chinese artists from earliest times. They represent the fire which Yang Jên, with his magic fan, caused to blaze forth and destroy Lü Yüeh, not germs of disease showered down by the latter on his foe.

It has been hinted above that possibly the Chinese at an early date were acquainted with organisms invisible to the naked eye. The suggestion is founded primarily on certain texts which seem to indicate the making of glass and lenses, and it is encouraged by the finding of glass objects, the design and provenance of which are consistent with an attribution to the Han dynasty (B.C. 206–A.D. 220). The ancient literature on the subject is mixed up with that on metallic mirrors used chiefly for kindling fire; hence there is danger of confusing terms of which the precise meanings have been lost. In a book, dating from the eleventh century B.C., and concerned with the regulation of rites and ceremonies, there is a passage stating that the officials for supervising light received the rays of the sun with a *fu-sui*. Native commentators declare this to have been the same as a *yang-sui*, a burning-glass or burning-mirror. Uncertainty whether a lens or mirror is meant seems to be cleared up to some extent by the first-century writer, Wang Ch'ung, who discourses on many institutions and beliefs of antiquity in a spirit of carping incredulity. But even he appears to accept the tradition that burning-glasses used for bringing down fire from the sun were made by fusing five kinds of "stone" or earthy substances. A Western parallel might be instanced in some ingredients of our own glass at the present day—viz., silica, lead oxide, potash, lime, and clay.[4] Without going further into this subject, it may be stated that the balance of evidence seems to favour the conclusion that in very ancient times the Chinese made glass, and, moreover, understood the properties of a lens. It is not stretching imagination very far to suppose that they used its magnifying powers to perceive things scarcely visible to the naked eye. Indeed, one might, after searching, find sufficient justification for a claim that telescopes were employed in ancient China for astronomical investigation (if such a thesis has not been advanced already). On the other hand, it appears very much less probable that anything in the nature of a microscope of high power existed or that the micro-organisms of disease were known in China prior to Western discoveries.

Your note entitled "Primitive Bacteriology," which gives rise to this letter, contains an anachronism connecting Fu Hsi with the sixth century A.D. Fu Hsi is a legendary emperor, said to have lived nearly 3000 years B.C. There is, too, a somewhat misleading suggestion that the main literary sources of Mr. Werner's book are "innumerable Chinese MSS." As that author frankly acknowledges, he quotes many long passages from the publications of Father Doré and Prof. H. A. Giles, and his chief native authorities are four or five comparatively modern printed books in common circulation. A vast mass of literature yet remains to be explored before an understanding be obtained of ancient Chinese medicine, myth, and legend.

I am, Sir, yours faithfully,

Jan. 6th, 1923. W. Perceval Yetts.

A DISCLAIMER.

To the Editor of The Lancet.

Sir,—As the author of a book, designed solely for medical men, on "Mistakes and Accidents of Surgery," may I have the hospitality of your pages in order to disclaim any connexion with the notices of that book which have appeared in the public press? I wish it to be known that I have not granted any interviews to journalists, nor have review copies of the work been forwarded to the lay newspapers.

I am, Sir, yours faithfully,

Portsmouth, Jan. 8th, 1923. Harold Burrows.

Obituary.

DAVID GEORGE THOMSON, C.B.E., M.D. Edin.,

LIEUTENANT-COLONEL, R.A.M.C.

The medical profession in Norwich has sustained a serious loss through the death on Jan. 4th of Dr. David Thomson, at the age of 66 years.

Dr. Thomson was born in Edinburgh and received a many-sided education, including courses at the College of Dunkirk and the Military School at Dresden. He took his M.D. with honours at Edinburgh University in 1881, thereafter devoting his attention to the study of mental disease. Having held the appointments of assistant medical officer in Derby County Asylum, Camberwell House, London, and the London County Mental Hospital at Cane Hill, he was appointed in 1886 to the medical charge of the Norfolk County Asylum at Thorpe, the senior county asylum, where he did his life-work. When he went there, the hospital afforded accommodation for 699 patients; on his resignation in 1922 numberless extensions and improvements had been carried out, and room found for over a thousand patients.

In March, 1915, the Thorpe Hospital was taken over by the War Office for the treatment of sick and wounded soldiers, the mental patients all being transferred elsewhere within a period of 12 days. Dr. Thomson, as officer-in-charge, superintended the structural alterations involved in the conversion of an asylum into a first-rate military hospital of 1000 beds, which involved an outlay of £16,000. After a year the accommodation was doubled by the erection of ten hutment wards, each of 60 beds, and some outdoor sleeping shelters. In the spring of 1918 a further hospital camp for about 500 men was added, raising the total available accommodation to 2428 beds, a number which was maintained until demobilisation in April, 1919. Altogether 44,651 officers and men were admitted, the total deaths during the four years numbering 423, or only 0·9 per cent. of the admissions. In addition to this heavy responsibility, Dr. Thomson was also asked to take over the military control of the 60 auxiliary hospitals in Norfolk to which convalescent cases were sent. When his war service was over Dr. Thomson was allowed to retain the honorary rank of Lieut.-Colonel, R.A.M.C., and was granted the C.B.E. On his final retirement from the Thorpe Hospital after 35 years of service, Dr. Thomson continued to act as medical adviser to the County Mental Deficiency Committee. He had been for many years an honorary consulting physician to the National Association for the Feeble-minded, and for five years he presided over the Medico-Psychological Association. Although his period of presidency coincided with the war he lost no opportunity of pressing for such urgent reforms as post-graduate training in psychiatry, improvement in the conditions of the asylum medical service, and provision of out-patient mental clinics.

In a county like Norfolk it is natural that Dr. Thomson's pastimes should have been yachting and camping, and he was an acknowledged authority on the natural history of the district. His love of music served him in good stead in institutional work; he organised excellent productions of Gilbert-Sullivan opera, his company on one occasion appearing for a week at the Norwich Theatre.

HARRY RAINY, M.D., C.M., F.R.C.P. EDIN., F.R.S. EDIN.

Dr. Harry Rainy, who died at his residence in Edinburgh on Jan. 4th, was in his sixtieth year, and had been in failing health for some time. He came of medical descent. Son of the late Dr. George Rainy, of Glasgow, his grandfather was professor of medical jurisprudence in Glasgow University. Dr. H. Rainy was educated first at the Edinburgh Academy and afterwards at the University, where he graduated M.B., C.M. in 1891, taking the first place in the honours list and holding the Ettles Scholarship awarded to the most distinguished graduate of the year. In the next few years he went on to take his M.D. degree and the M.R.C.P. Edin., being later elected a Fellow. He became a Fellow of the Edinburgh Royal Society, and in 1907 he was honoured by the University of Upsala with the M.D. hon. caus.

Dr. Rainy's appointments were all held in Edinburgh. He was first resident medical officer to the Chalmers' Hospital, then physician to the New Town Dispensary, and medical electrician to the Royal Hospital for Sick Children. He soon was elected to the medical staff of the Royal Infirmary, where he was physician, third in seniority, at the time of his death. A year ago he was appointed medical adviser to the Prison Commission in Scotland, and quite recently succeeded the late Sir James Affleck as physician to the Longmore Hospital. The medical school made him lecturer in the principles and practice of medicine, and he also lectured at the University on physical methods in the treatment of disease. He took an active part in the work of the Royal College of Physicians of Edinburgh as hon. secretary and examiner, and only a few months ago retired from the office of vice-president. He also examined in medicine at the University of Aberdeen.

But although Dr. Rainy's voice was only heard by Edinburgh students his teaching reached a vastly wider circle, for he was joint author with Dr. R. Hutchison of "Clinical Methods," a book which first appeared in 1897 and which has profoundly influenced medical practice. It was not designed as a treatise on diagnosis, but simply to set out the methods of clinical investigation by which alone correct diagnosis can be reached. To this book Dr. Rainy contributed the sections on electrical examination of muscle and nerve, on alimentary parasites, on the microscopy of the urine, and on clinical bacteriology, as well as the more general chapters on the circulatory and respiratory systems. The book has passed through seven editions and has long been familiarly known by the names of its authors. To-day, when "clinical pathology" is part of the regular curriculum and handbooks to it of all sizes abound, the pioneer work in this field of Dr. Rainy and his colleague is worth remembering with gratitude.

In other than medical work Dr. Rainy brought to bear an accurate and logical mind. He was an elder in the United Free Church and discriminatingly interested in various kinds of philanthropic work. He remained unmarried.

Medical News.

UNIVERSITY OF VIENNA.—A post-graduate course on diseases of the skin and venereal diseases will be held from Feb. 12th to 24th, followed by a practical course from Feb. 26th to March 3rd. Those interested are invited to communicate with Dr. A. Kronfeld, 22 Porzellangasse, Vienna IX. Post-graduate instruction in all branches of medicine and surgery is being given during this session under the auspices of the faculty of medicine. The bureau of information as regards these courses is at 8 Frankgasse, Vienna IX.

ROYAL SANITARY INSTITUTE.—A meeting will be held on Feb. 2nd and 3rd in the University, Edmund-street, Birmingham, when a discussion on Town and Country Milk Supplies: What is Needed for their Improvement, will be opened by Dr. John Robertson at 7.30 P.M. Prof. H. R. Kenwood will preside. On Feb. 3rd a visit will be paid to milk plants to demonstrate methods of pasteurisation and sterilisation and bottling.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting will be held at the Miller General Hospital, Greenwich, to-day, Friday, Jan. 12th, at 8.45 P.M., when Dr. W. H. Payne, the President, will occupy the chair. Dr. Hildred Carlill will show the following cases: (1) Syphilis of the Nervous System and Encephalitis Lethargica; (2) Plantar Ulcers in Diabetes Mellitus; (3) Tabes Dorsalis with Charcot's Disease of the Tarsus. Dr. E. P. Cumberbatch will show (1) Epithelioma of the Skin treated by Diathermy; (2) Black Mole in course of treatment by Fulguration. Cases will also be shown by Dr. Arthur Davies and Dr. H. Nockolds.

PROFESSORSHIP OF PHYSIOLOGY, TRINITY COLLEGE, DUBLIN.—The Visitors of Dublin University have sanctioned a decree of the Board of Trinity College establishing a chair of Physiology in the College. Up to the present the duty of teaching physiology has been on the King's Professor of the Institutes of Medicine, who is appointed, under the School of Physic Acts of 1800 and 1867, by the President and Fellows of the Royal College of Physicians of Ireland. It is understood that the Board of Trinity College will appoint the existing King's Professor to the new chair, so that he will occupy both chairs. No difficulty is likely to arise during his tenure of office, but when the necessity for a fresh appointment occurs it is possible that the two institutions will not see eye to eye. While not actually opposing the decree establishing a new chair in Trinity College, the President and Fellows of the Royal College of Physicians made it clear that they took no responsibility for the step, and that they had no power to diminish their discretion in the choice of a King's Professor.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—A post-graduate course will be held from Jan. 22nd to March 23rd. Lectures on the Pathology of the Nervous System will be given by Dr. J. Godwin Greenfield on Mondays, at 12 noon, and lectures on the Anatomy and Physiology of the Nervous System will be given if sufficient entries are received. Out-patient clinics will be held on Mondays, Tuesdays, Thursdays, Fridays, at 2 P.M., and clinical lectures and demonstrations on the same days at 3.30 P.M. Those taking part in the course include Dr. James Taylor, Dr. Grainger Stewart, Dr. W. J. Adie, Dr. S. A. Kinnier Wilson, Dr. F. M. R. Walshe, Dr. Gordon Holmes, Dr. P. W. Saunders, Dr. C. M. Hinds Howell, Dr. Aldren Turner, Mr. T. H. Just, Dr. J. S. Collier, Mr. Leslie Paton, Dr. Risien Russell, Mr. Sydney Scott, Mr. D. J. Armour, Dr. L. D. Bailey, and Mr. P. Sargent. The fee for the whole course, including anatomy and physiology, is £12 12*s.*; but these lectures may be taken separately for a fee of £4 4*s.* Course without anatomy and physiology lectures will be £10 10*s.* Any part of the course may be taken separately at a special fee. Fees should be paid to the Secretary of the Hospital, Queen-square, Bloomsbury, on entering for the course.

Messrs. Cassell announce the forthcoming appearance of a new book by Sir Frederick Treves under the title "The Elephant Man and other Reminiscences."

London Dermatological Society.—A meeting will be held at 4.30 p.m. on Jan. 16th, at St. John's Hospital, 49, Leicester-square, London, W.C. 2, when Dr. M. G. Hannay will communicate some remarks on urticaria.

The *Chesterfield Lectures*, founded in 1895 to promote the study of dermatology, are being held at St. John's Hospital on Thursdays at 5 p.m., and are free to practitioners. The next lecture will be given on Jan. 18th by Dr. W. K. Sibley on Electrical Treatments and Diathermy.

The late Dr. F. J. Pearson.—The death occurred on Jan. 2nd, at the age of 59, of Dr. Francis James Pearson, who had practised medicine at Owston Ferry, Lincolnshire, for nearly 20 years. Dr. Pearson qualified M.R.C.S., L.R.C.P. from St. Mary's Hospital in 1896, and became house surgeon to the Barrow-in-Furness Hospital in the same year. During the Boer War he worked as a civil surgeon at Netley Hospital and later volunteered for plague duty in India, where he served for 18 months. He then settled at Owston Ferry and was there much beloved.

Jenner Centenary Exhibition.—In connexion with the commemoration of the centenary of the death of Dr. Edward Jenner, on Jan. 26th, the Wellcome Historical Medical Museum is arranging a special exhibition of personal relics, pictures, engravings, drawings, documents, MSS., and letters relating to the discovery of vaccination. Anyone willing to lend objects of interest is asked to communicate with the Curator at 54a, Wigmore-street, London, W. Loans while on exhibition will be insured and any expense incurred in transit will be paid by the Museum. The exhibition is to be opened on Jan. 26th and to remain open for some months.

Belgian Society of Gynæcology and Obstetrics. An invitation has been received from the members of this Society addressed to their British colleagues. In this the secretary-general of the Society announces that any members of the Section of Obstetrics and Gynæcology of the Royal Society of Medicine, or of societies of similar aim and scope, will be made welcome at the meetings of the Belgian Society if they visit Brussels. The meetings of the Belgian Society are held in the afternoon of the first Saturday of each month at 3, rue du Maelbeek, Brussels, and the officers of the Society for the current year are: Dr. Edmond Rouffart, President; Dr. Jean-Louis Henrotay, Vice-President; Dr. H. E. Nisot-Wuyts, Treasurer; and Dr. Max Cheval, 37, rue Joseph II., Brussels, is the Secretary-General.

Doctors and Dentists under the Dangerous Drugs Act.—The Home Office has issued a memorandum defining the duties and obligations of the registered medical man and dentist in regard to the Dangerous Drugs Act of 1920. Two clauses in this memorandum call attention to the penalties which may be incurred by non-observance of the regulations.

> A doctor or dentist who obtains, or attempts to obtain, the drugs for a purpose not covered by his authorisation, or who infringes any of the regulations, commits an offence against the Act, and, if convicted, is liable to a fine of £200, or to imprisonment, with or without hard labour, for six months, or to both fine and imprisonment.
>
> Further, the Home Secretary has power, after the conviction of any doctor or dentist, to withdraw from him his authorisation; the effect of this would be to deprive him entirely of the right to be in possession of or to supply the drugs.

The memorandum is to be printed as a pamphlet and issued for sale by H.M. Stationery Office.

Royal Institute of Public Health.—A course of ten lectures on tuberculosis and venereal disease will be delivered in the Lecture Hall of the Institute, 37, Russell-square, London, W.C., on Wednesdays, at 4 p.m., starting on Jan. 17th. The first lecture will be delivered by Prof. S. Lyle Cummins on the Need of Research to Guide the Framing of Tuberculosis Schemes. On Jan. 24th Dr. W. T. Gordon Pugh will speak on Surgical Tuberculosis in Children, and on Jan. 31st Dr. A. Lisle Punch on Laboratory Methods in the Investigation of Tuberculosis. Dr. James Watt will deal with Principles and Practice of Sanatorium Treatment on Feb. 7th, and Dr. A. Hope Gosse with Public Health Aspects of Pulmonary Tuberculosis on Feb. 14th. The five lectures on Venereal Disease will include the organisation and administration of venereal disease schemes, venereal clinics—their function and organisation, venereal disease under army organisation, the prevention of congenital syphilis, and the industrial menace of syphilis, by Colonel L. W. Harrison, Mr. E. R. Townley Clarkson, Major A. T. Frost, Dr. J. H. Sequeira, and Dr. W. J. O'Donovan, respectively. Admission is free to medical men and others interested in the subjects.

Tuberculosis Society.—A meeting of this society will be held at Margaret-street Hospital, London, W. 1, on Monday, Jan. 15th, at 7.30 p.m., when Dr. James Crocket will read a paper entitled A Survey of Ten Years' Work in Tuberculosis.

Royal Statistical Society.—A meeting will be held at 5.15 p.m. on Tuesday, Jan. 16th, in the Hall of the Royal Society of Arts, John-street, Adelphi, London, W.C. 2, when Dr. R. Dudfield will open a discussion on the Registration of Disease.

Haslemere and District Hospital.—This hospital will be opened on Jan. 20th, at 2 p.m., by Viscount Cave. It contains 35 beds, including a maternity ward and X ray department, and has been built and paid for at a cost of over £32,000.

Sir Norman Walker.—The Scottish Board of Health has recorded its deep satisfaction that the honour of knighthood should have been conferred on Dr. Norman Walker, to whom the Board has been frequently indebted for valuable assistance and advice—more especially in his capacity first as vice-chairman and latterly as chairman of the Medical and Allied Services Consultative Council.

Medical Prayer Union.—A meeting will be held, by invitation of Dr. J. Burnett Rae, at 98, Portland-place, London, W. 1, on Thursday, Jan. 25th, at 8 p.m., when Right Rev. E. A. Knox, D.D., late Bishop of Manchester, will read a paper, and Miss Muriel Michell will sing. Intimation of intention to be present should be addressed to the hon. secretary, Dr. Tom Jays, Livingstone College, Leyton, E. 10.

Dublin (83rd) General Hospital.—Nineteen members of the Dublin (83rd) General Hospital staff met at the annual dinner on Jan. 6th, at Mills's Hall, under the presidency of Colonel Sir William Taylor, K.B.E., who had organised the team. Since their previous dinner the team has lost one member, Mr. Edward Taylor, who died last April. Dr. A. R. Parsons was prevented from attending by illness and Dr. E. J. M. Watson by an accident, whilst others, who lived at a distance, were unable to make the journey to Dublin under present conditions. Among the members of the team present was Major-General M. R. J. Hayes, the Director-General of the Army Medical Service of the Free State. Replying to the toast of his health, General Hayes thanked his late colleagues for the cordial help given to him and to the soldiers of the Free State Army by the staffs of the several Dublin hospitals.

Voluntary Hospitals Commission.—At a meeting of representatives of local voluntary hospital committees held in July last, it was decided to adopt a proposal made by the Voluntary Hospitals Commission to establish a small consultative committee of members of local committees. The purpose of this committee is to provide a body closely in touch with local opinion, to which the Commission could refer for assistance and advice. The Commission, after inviting nominations from local hospital committees, have now appointed the following to be a consultative committee for England and Wales: Rt. Hon. F. D. Acland (Devonshire), Alderman E. C. Barnes (Derbyshire), Capt. W. Best (North Wales), Mr. J. J. Cockshott (Lancashire), Rev. G. B. Cronshaw (Berks, Bucks, and Oxon.), Mr. H. N. Crouch (Somerset), Sir James Curtis (Birmingham and Gloucestershire), Mr. Walter Davies (Manchester), Sir David Drummond, M.D. (Northumberland), Mr. H. W. C. Drury (Norfolk), Sir Henry Hadow (Sheffield), Mr. Noel Hanbury (Hampshire), Viscount Lascelles (East and West Ridings of Yorkshire), Col. R. J. S. Simpson, M.B. (Kent), Sir A. Garrod Thomas, M.D. (Monmouthshire), Bishop Welldon (Durham).

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Capt. M. L. Rodd is placed on the retd. list with rank of Surg. Rear-Admiral.

The following Surg. Comdrs. have been placed on the retd. list with the rank of Surg. Capt.: E. S. Tuck, W. E. Mathew, W. H. O. Garde, A. H. H. Vizard, J. Boyan, J. A. Forrest, A. X. Lavertine, and J. W. Craig.

The following appts. have been notified:—Surg. Capts.: R. F. Clark to *Maine*; F. H. Nimmo and W. E. Ormsby to *Vivid*, for R.N. Barracks; R. J. MacKeown to *Pembroke*, for R.N. Barracks. Surg. Comdrs.: F. H. Stephens to *Victory*, for R.N. Barracks; F. H. Holl to *President*, addl. temp., for R.N. College and School, Greenwich; R. Hughes to *Dido*; and C. G. Sprague to *Constance* on recommissioning. Surg.-Lt. Comdrs. J. B. Crawford to *Courageous*, temp.;

and T. J. O'Riordan to *Dido*. Surg.-Lts. E. J. Benson to *Cyclops;* T. N. D'Arcy to *Egmont* and for Malta Dockyard; and W. E. Heath to *Ceres*.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. A. M. MacLaughlin retires on retd. pay and is granted the rank of Col.

Capt. J. E. Hepper retires, receiving a gratuity, and is granted the rank of Maj.

MILITIA.

Capt. R. Forgan relinquishes his commn. and retains the rank of Capt.

TERRITORIAL ARMY.

Capt. A. S. Bruzaud to be Maj.

Capt. C. W. Dudley (late R.A.M.C., Spec. Res.) to be Capt.

Capt. F. G. L. Dawson to be Adjt. (S. Middlesex) Divn., R.A.M.C., T.A.

Capts. H. S. Wallace and A. J. Walton relinquish their commns. and retain the rank of Capt.

Capt. J. A. Paterson resigns his commn. and is granted the rank of Maj.

General Hospitals: Capts. H. A. Lucas and P. R. Bolus, from Genl. List, to be Capts.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

List of probable papers:—Thursday, Jan. 18th.—J. Barcroft: Observations on the Effect of High Altitude on the Physiological Processes of the Human Body. Prof. F. W. MacBride: Some New Light on the Inheritance of Acquired Characters. C. F. Cooper: *Baluchitherium osborni* (? syn. *Indricotherium turgaicum*, Borrissyak). (Communicated by Dr. A. S. Woodward). J. A. Gunn and K. J. Franklin: The Sympathetic Innervation of the Vagina. (Communicated by Sir Charles Sherrington). H. G. Cannon: On the Metabolic Gradient of the Frog's Egg. (Communicated by Prof. E. W. MacBride). Basiswar Sen: On the Relation between Permeability Variation and Plant Movements. (Communicated by Sir William Bayliss). H. L. Duke: An Inquiry into an Outbreak of Human Trypanosomiasis in a *Morsitans* Belt to the East of Mwanza, Tanganyika Territory. (Communicated by Mr. C. Dobell). ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, Jan. 16th.

GENERAL MEETING OF FELLOWS: at 5 p.m.

Ballot for the election of Candidates.

PATHOLOGY: at 8.30 p.m.

Prof. M. J. Stewart and Dr. J. le F. C. Burrow: Malignant Spheno-Occipital Chordoma.

Dr. A. J. Eagleton and Miss E. M. Baxter: The Serological Classification of Virulent *B. Diphtheriæ*.

Dr. C. C. Okell and Miss E. M. Baxter: The Fermentative Reactions of Virulent *B. Diphtheriæ*.

NEUROLOGY:

Members of this Section are cordially invited to attend the above meeting.

Wednesday, Jan. 17th.

HISTORY OF MEDICINE: at 5 p.m.

Papers:

Mr. W. H. S. Jones: Medical Etiquette in Ancient Times.

Dr. Charles Singer: The Hippocratic Oath.

Thursday, Jan. 18th.

DERMATOLOGY: at 5 p.m. (Cases at 4.30 p.m.)

Cases will be shown.

Special Evening Meeting at 8.30 p.m.

Papers:

Dr. J. W. McNee and Dr. A. M. H. Gray: A Chemical and Histological Study of a Case of Sclerema Neonatorum.

Dr. J. E. R. McDonagh: On the Use of Manganese as a Chemo-Therapeutic Preparation.

Friday, Jan. 19th.

OTOLOGY: at 5 p.m. (Cases at 4.45 p.m.)

Demonstration:

Dr. Logan Turner and Dr. J. S. Fraser: Labyrinthitis as a Complication of Middle-Ear Suppuration.

Cases:

Sir James Dundas-Grant will show a case of Vertigo with Fixation of Ossicles; cured by Ossiculectomy.

Other cases and specimens will be shown.

ELECTRO-THERAPEUTICS: at 8.30 p.m.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

Thursday, Jan. 18th.—8.15 p.m. (preceded by a demonstration at 7.45 by Dr. A. C. Stevenson, on the Pathology of the Brain in Sleeping Sickness).

Papers:

Dr. George C. Low and Dr. Philip Manson-Bahr: The Treatment of Human Trypanosomiasis by "Bayer 205."

Dr. A. C. Stevenson: The Pathology of the Brain in Sleeping Sickness.

Dr. C. Morley Wenyon: The Trypanocidal Action of the Serum and Cerebro-Spinal Fluid of Cases Treated by "Bayer 205"; and on the Strain of Trypanosome Isolated from Case 9.

Dr. J. G. Thomson: Trypanocidal Action of the Urine in Case 9.

(Some of the treated cases will be present).

Dr. C. C. Chesterman (of the Belgian Congo): The Action of Tryparsamide in Sleeping Sickness: A Study of Forty Cases, with Special Reference to the Cerebrospinal Fluid.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Monday, Jan. 15th.—11 a.m., Mr. Simmonds: Applied Anatomy. 2 p.m., Mr. Addison: Surgical Wards. 4 p.m., Dr. Saunders: Cretins and Athyroidism.

Tuesday.—11 a.m., Dr. Paterson: Demonstration of Medical Cases. 12 noon, Dr. Burrell: Chest Cases. 2.30 p.m., Mr. Tyrrell Gray: Surgical Wards.

Wednesday.—10 a.m., Dr. Saunders: Medical Diseases of Children. 2.30 p.m., Mr. Donald Armour: Surgical Wards. 4 p.m., Dr. Burnford: Clinical Pathology in Practice.

Thursday.—10 a.m., Dr. Grainger Stewart: Neurological Department. 12 noon, Mr. Simmonds: Demonstration of Fractures. 2 p.m., Mr. Bishop Harman: Eye Department.

Friday, 12 noon, Dr. Flett: Radiology. 2 p.m., Mr. Banks-Davis: Diseases of Throat, Nose, and Ear. 3 p.m., Mr. Sinclair: Surgical Cases.

Saturday.—9 a.m., Dr. Burnford: Bacterial Therapy. 10 a.m., Dr. Saunders: Medical Diseases of Children. 11 a.m., Mr. Maingot: Surgical Pathology.

Daily, 10 a.m. to 6 p.m., Saturdays, 10 a.m. to 1 p.m.: In-patients, Out-patients, Operations, Special Departments.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, Marylebone, W.

(Post-graduate Intensive Course in Cardiology: final week.)

Monday, Jan. 15th.—10 a.m., Dr. Parsons-Smith: The Electrocardiograph. 11.15 a.m., Dr. F. W. Price: Angina Pectoris. 2 p.m., Dr. R. O. Moon: Ward Demonstration. 3 p.m., Dr. J. Strickland Goodall: Out-patients.

Tuesday.—10 a.m., Dr. F. W. Price: Diseases of the Myocardium. 11.15 a.m., Dr. J. Strickland Goodall: Aortic Disease. 2 p.m., Dr. F. W. Price: Ward Demonstration. 3 p.m., Sir S. Russell-Wells: Out-patients.

Wednesday.—10 a.m., Dr. Parsons-Smith: Heart Block. 11.15 a.m., Dr. P. Hamill: Congenital Heart Disease. 2 p.m., Dr. H. B. Weir: Pathological Demonstration. 3 p.m., Dr. R. O. Moon: Out-patients.

Thursday.—10 a.m., Dr. R. O. Moon: Cardiac Arrhythmias. 11.15 a.m., Dr. F. W. Price: Diseases of the Arteries. 2 p.m., Dr. Parsons-Smith: Ward Demonstration. 3 p.m., Dr. F. W. Price: Out-patients.

Friday.—10 a.m., Dr. J. Strickland Goodall: Tachycardia. 11.15 a.m., Dr. John Parkinson: Treatment of Heart Failure. 2 p.m., Sir S. Russell-Wells: Ward Demonstration. 3. p.m., Dr. John Parkinson: Out-patients.

Saturday.—10 a.m., Dr. P. Hamill: Ward Demonstration.

HOSPITAL FOR SICK CHILDREN, Great Ormond-st., W.C.

Thursday, Jan. 18th.—4 p.m., Dr. Still: Congenital Hypertrophy of the Pylorus.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.

Thursday, Jan. 18th.—5 p.m., Dr. W. K. Sibley: Electrical Treatments, Diathermy, &c.

ST. MARY'S HOSPITALS, Manchester.

The post-graduate lecture (at Whitworth-street West Branch), fixed for Jan. 19th, has been postponed to March 9th. There will not be any lecture on Jan. 19th.

Appointments.

Mackintosh, Jean M., M.B., Ch.B. Edin., D.P.H., has been appointed Assistant Medical Officer of Health and School Medical Officer at Llanelly.

McKerlie, H., M.B., Ch.B. Glasg., House Surgeon, Clayton Hospital, Wakefield.

Oswald, J. A. Ramsay, M.B., Ch.B. Glasg., House Surgeon, Perth Royal Infirmary.

Certifying Surgeons under the Factory and Workshop Acts: Wallace, H. S., M.B., Ch.B. Edin. (Nottingham, West District); France, W. H., M.D. Durh., L.R.C.P. Lond., M.R.C.S. (Selston); and Lowther, R. C., M.B., Ch.B. Edin. (Grange-over-Sands).

Vacancies.

For further information refer to the advertisement columns.

All Saint's Hospital for Genito-Urinary Diseases, Vauxhall Bridge-road, S.W.—Res. H.S. £160.

Belgrave Hospital for Children, Clapham-road, S.W.—Hon. Radiologist. 50 guineas. Also Anæsthetist. 25 guineas

Birmingham City.—Research Officer. £500.

Birmingham University, Faculty of Medicine.—Asst. Lecturer in Pathology. £300.

Chelsea Infirmary, S.W.—Second Asst. M.O. £325.

City of London Hospital for Diseases of Chest, Victoria Park, E.—Res. M.O. £250.

Colchester, Essex County Hospital.—Cas. O. and Path. £200.

Dartford, City of London Mental Hospital, near Dartford, Kent.—Second Asst. M.O. £350.

Derby County Mental Hospital, Mickleover.—Jun. Asst. M.O. £350.

Dreadnought Hospital, Greenwich.—H.P. £150. Also S. for Dis. of Throat, &c.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—H.P. £125.

Elizabeth Garrett Anderson Hospital, Euston-road.—Asst. Obstet.

Gloucestershire Royal Infirmary and Eye Institution, Gloucester.—Asst. H.S. £150.

Hospital for Consumption and Diseases of the Chest, Brompton.—Asst. Res. M.O. £150. Also H.P. £50.

Hove Hospital.—Res. M.O. £250.

King Edward VII. Sanatorium, Midhurst, Sussex.—Second Asst. M.O. £250.

Liverpool, David Lewis Northern Hospital.—Two H.P.'s and Four H.S.'s. Each £100.

London County Mental Hospital Service.—Seventh A.M.O. £300.

Maidstone, West Kent General Hospital.—H.S. £220.

Manchester, Ancoats Hospital.—Hon. Radiologist. £100.

Manchester Royal Infirmary.—Anæsthetist. £50.

Margate, Royal Sea Bathing Hospital for Surgical Tuberculosis.—Res. S. and Med. Super. £500.

Northampton General Hospital.—H.S. £200.

Rotherham Hospital.—Jun. H.S. £150.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Pathologist. £200.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. £80.

Scarborough Hospital and Dispensary.—H.S. £150.

Sheffield Royal Hospital.—H.S. to Ear, Nose, and Throat Dept. and Asst. Cas. O. £150.

Sheffield Royal Infirmary.—Ophth H.S. £150.

Sheffield University, Dept. of Path. and Bact.—Asst. Bact. and Dem. in Path. Each £300.

Shoreham, Sussex, Lancing College.—School Doctor. £500.

Staffordshire General Infirmary, Stafford.—H.S. £200.

University of London.—External Examiners, &c.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Hon. Asst. Surg.

Whittingham County Mental Hospital, near Preston, Lancs.—Asst. M.O. Also Asst. M.O. Pathologist. Each £449 13s.

Wigan Infirmary.—Hon. Asst. Physician.

Willesden General Hospital, Harlesden-road, N.W.—Hon. Anæsth.

Wrexham Infirmary.—H.S. £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointment: Cockermouth (Cumberland).

The Home Secretary gives notice that in consequence of the resignation of Mr. Henry Hind, one of the Medical Referees under the Workmen's Compensation Act, 1906, for the Harrogate, Ripon, and Tadcaster County Courts in Circuit No. 15, the appointment held by him is vacant. Applications for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than Jan. 31st, 1923.

Births, Marriages, and Deaths.

BIRTHS.

ALLAN.—On Jan. 8th, at Primrose Mansions, Battersea Park, the wife of Dr. C. H. Allan, W.A.M.S., of a daughter.

SEDGWICK.—On Jan. 5th, at Lower Seymour-street, W., the wife of Dr. C. Humphrey Sedgwick, of Weedon, Northants, of a son.

THOMPSON.—On Jan. 6th, at Elmfield, Taunton, the wife of James Thompson, M.C., M.B., F.R.C.S. Eng., of a son.

MARRIAGES.

BOYD—ORR.—On Jan. 5th, at Dundas-street Congregational Church, Glasgow, William Ernest Boyd, M.A., M.D., to Kathleen Edith Gemmill, only daughter of Mr. James M. Orr, of Athole Gardens-place, Glasgow, W.

ORME—MACAULAY.—On Jan. 3rd, at St. Peter's Church, Ludlow, E. Stuart Orme, M.B., to Helen, second daughter of Mr. and Mrs. F. W. Macaulay, of Springfield House, Ludlow.

DEATHS.

GAITSKELL.—On Dec. 31st, 1922, at Westcliff-on-Sea, Herbert Ashley Gaitskell, M.D., aged 49.

PEARSON.—On Tuesday, Jan. 2nd, at Owston Ferry, Francis James Pearson, M.R.C.S., L.R.C.P., aged 59 years.

PRINGLE.—On Dec. 18th, at Christchurch, New Zealand, Dr. John James Pringle, M.B., C.M. Edin., F.R.C.P. Lond., for many years physician to the Middlesex Hospital, W., in his 68th year.

STEEN.—On Jan. 4th, at Broadway, Letchworth, Herts, William Carmichael Steen, M.D., in his 60th year.

THOMSON.—On Jan. 4th, at the residence of his son-in-law, R. M. Winder, Lingwood Lodge, near Norwich, Lieut.-Colonel David George Thomson, M.D., C.B.E., late superintendent of the Norfolk Mental Hospital, aged 66.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

SOME ECONOMIC FACTORS IN DENTISTRY.

BY A. BYGOTT, M.D. LOND., D.P.H.,
BARRISTER-AT-LAW; MEDICAL OFFICER OF HEALTH, COUNTY OF WEST SUFFOLK.

THE Dentists Act of 1921 came into operation on Nov. 30th, 1922, so that any person whose name is not on the Dental or Medical Registers will apparently now be prevented from practising dentistry under a penalty of £100. This Act has added nearly 8000 names to the 5000 and more already on the register under the Dentists Act of 1878. These changes, marking a new era, require a careful survey of the economic aspect of dentistry. The conflicting claims of the two schools of economics—one that the country cannot afford to pay for a proper dental service, the other that she cannot afford to do without it—require careful consideration. The following figures are taken from the annual report of the Registrar-General for 1920, which appear better suited to my present purpose than those obtained from the recent Census. The estimated population of England and Wales was 37,524,000, of these 3,280,117 were under 5 years of age, 7,515,793 between 5 and 15; 17,895,484 between 15 and 45, and 8,832,606 between 45 and 85. Each of these age-groups has its special dental difficulties. There were 294 deaths due directly to diseases of the teeth and gums, and 6 deaths under anæsthetics administered for the extraction of teeth. There are about 10 million insured persons in the country entitled to medical benefit which is supplied by about 11,000 panel doctors. The problem is to make everybody in this country realise the importance of dental treatment, to wish to procure this for themselves and for the rest of the community.

Present Provisions of Dental Service.

The following provision is made by public authorities for dental service. The education authorities in England and Wales numbering 316 employ 447 school dentists, many part-time only, who deal with a school population of about 6 million. Some dental work is done under maternity and child welfare schemes; some authorities, in connexion either with sanatoriums, or tuberculosis schemes, provide a limited amount of dental service. Some boards of guardians supply dental treatment for children under their care. Charitable assistance is available in special dental hospitals, or, to a more limited extent, in dental departments of general hospitals. The Surgical Aid Society and the Ivory Cross pay institutions or local dentists for service to poor people under their schemes. Dental assistance was regarded as a very appropriate additional benefit to be supplied after the friendly societies had obtained further experience by providing medical benefit under the Insurance Act, and were assured that funds were sufficient to provide additional benefits. There are, I am informed, about six dental clinics in the country registered under the Company's Act, managed and staffed by registered dentists, including those at Bournemouth, Brighton, Redhill, and Reading, for the supply of dental services to persons under a fixed income limit at a fixed scale. The object of these associations is to provide good treatment for the patients rather than to make a profit. Several friendly societies avail themselves of the services of the National Insurance Beneficent Society, which enables insured persons to obtain adequate dental service when needed. It will be seen, however, that a very large section of the population, many of whom are dependents on insured persons, are not provided for by the schemes. It is very important that both the medical and dental needs of this section of the population should be met. Owing to unemployment a large number of people lack the necessary food to keep them industrially efficient, and this is not a favourable time to ask for money for the provision of sound teeth with which to eat their insufficient food-supply. Nevertheless, the health and strength of many thousands of people is their only capital and anything which impairs their health is an attack on all that they possess, including their lives.

Dental Legislation.

A dental board has been established in charge of a registrar, and in future all persons practising dentistry must be registered. Many people think that dental practice consists either in pulling out teeth or in buying new ones, and they do not realise that by cleanliness, periodical inspection, and conservative treatment, they ought to preserve their natural teeth as long as possible. In 1878, when the first Dentists Act was passed, matters were much worse than they are now, but a great deal was being done to improve the national health. The Elementary Education Act of 1870, the Public Health Act, 1875, and the fusion of the Poor-

Law Board and Board of Health in the Local Government Board had followed the surgical revolution introduced by Lord Lister's antiseptic methods in the later "sixties." The first Dentists Act followed the lines of the Medical Act of 1859; unqualified practice was not prohibited, but the public was given an opportunity of knowing which practitioners were qualified and which were not. Unqualified medical practice is limited, owing to the possibility of prosecution for manslaughter, and the tightening up of death certification in 1874; but as the unqualified dentist's only disability was difficulty in enforcing the payment of fees, which might be got over by insisting on payment in advance, or by patients' ignorance of the law, the qualified dentist has been exposed to very unfair competition since the passing of the Dentists Act, 1878.

The Dental Register.

In 1918, 5524 names were on the Register, of which number 4214, or 75 per cent., were qualified as the result of licences from colleges or universities, and 1274 persons were registered at the time of the passing of the Act, in 1878, as engaged in the practice of dentistry. It is specially interesting to note that in 40 years 25 per cent. of the originally registered were still alive, although some of them must on account of old age have ceased to practise. In 1878 the proportion of dentists to the rest of the population was 1 to 6500 and in 1917 1 to 8500. In 1879 the population of the United Kingdom was 34,156,113, the number of names on Medical Register 22,600; in 1916 population was 46,431,546, and the number of names on the Medical Register 43,225. In 1918 about 2000 unqualified dentists belonged to dental societies; of these 1650 were members of the Incorporated Dental Society, an association of unregistered dentists which has endeavoured to regulate to some extent the conduct of its members. The number of unregistered practitioners registered up to November, 1922, was about 8000—a number considerably in excess of the registered dentists on the Register before the passing of the 1921 Act, as the door has been widely opened to the unqualified practitioner. The dentists with university or college qualifications in the Register are scattered over the British Isles and abroad; and many of them reside either in London or in populous and fashionable centres where they are likely to receive good fees for their work. In London, 75 practitioners are registered as residing in Harley-street and 45 in Wimpole-street. In East Ham, with its population of 133,000, there were no qualified men. In the county borough of Northampton, with a population of 87,000, there were 5 qualified and 20 unqualified men.

The Problem of Expense.

One of the witnesses before the Dentists Act Committee thought that a qualified dentist might, on the present basis of requirement, deal with a population of 4000. This would necessitate between 9000 and 10,000 dentists to deal with the population of England and Wales. The proportion of dentists to population would have to be much greater if the needs of the whole population were adequately met. If £1000 be taken as a basis for remuneration and working expenses of each dentist this would cost about £10,000,000. Such a system would involve regular distribution of dentists over the country, and the complete elimination of waste by competition, a condition which could not be realised. Every £100 added to the estimated cost of each dentist would make a difference of £1,000,000. (It is interesting to compare these figures with the cost of elementary education, which was estimated at £50,000,000 for 1922.) A very considerable portion of the money is being found at present from private sources, either through individual payments to dentists, or through public authorities for the dental services they provide. The Ministry of Pensions, the National Insurance Beneficent Society, the Surgical Aid Association, and the Ivory Cross usually pay fees to practitioners on about the following scale (taken from the National Insurance Beneficent Society): A partial denture of one to three teeth on vulcanite plate is £1; full or nearly full upper or lower denture is £3 5*s.*; complete upper and lower denture is £6; fillings 5*s.* with root treatment 12*s.* 6*d.* The fee for extractions with local anæsthetic is 2*s.* 6*d.* per tooth, and if under nitrous oxide gas, 5*s.* for anæsthetic and 2*s.* 6*d.* for each tooth extracted. There are, of course, very serious objections to the payment per tooth for multiple extractions. The wage of many agricultural labourers, and of many unskilled workers in the towns, is between £1 and 30*s.* a week, when employed, so that it is impossible for these people to pay even such moderate fees. Experience amongst panel or hospital patients in maternity and child welfare centres shows that the ordinary condition of working people's teeth is very bad indeed; it is impossible to leave the provision of dental service for them to private enterprise.

The question of providing for the poorer middle-class is very serious, as members of a very large number of families, including those of poorer members of the learned professions, are unable to provide or compelled to postpone treatment, owing to what are, to them, the high and uncertain fees of the ordinary dentist. A regular recognised scale of fees would be a great benefit, especially to this class of patient, and it may be that the scale adopted by the dental clinics already existing in a few towns or the National Insurance Beneficent Society may do something to stabilise dental charges. There is, of course, another side to this question: the ordinary out-of-pocket expenses of a dentist are very heavy, and when a man is in practice alone, his earning capacity is limited by his number of working hours. For instance, 7*s.* 6*d.* is considered by some people as a very heavy charge for filling a tooth, but as two interviews are often necessary, and possibly nearly half an hour is taken up in doing it, such a charge cannot be regarded as extortionate.

Education and Coöperative Effort.

The dentist's education is expensive. The calendar of the University of Birmingham shows that a student's expenses whilst obtaining the degree of B.D.S., including examination fees, amount to £186 12*s.*, and for the licence of Dental Surgery to £144 4*s.* 6*d.*; for a medical degree at the same university the expenses amount to £197. The duration of the course for both dental and medical degrees in this University is five years, and for the L.D.S. four years. During this time the student has to be maintained; at present cost of living, if he is not living at home, this would amount to from £100 to £150 per annum, so that the cost of dental education is about £1000, apart from the uncertainty of passing the necessary qualifying examinations. Patients when describing interviews, especially with unregistered dentists, often state that they have been told that the cost of the work must be high on account of the price of the materials used. Gold at the present moment is worth about £4 10*s.* per oz., ½ oz. goes a long way, and other materials such as vulcanite and stock teeth are quite cheap; these expenses afford no justification for the fees charged by some dentists on that account—but dental work must be expensive because of the value of the professional skill employed. Efficiency might be improved, and costs reduced, by coöperative effort. For instance, many dentists employ their own mechanics, the ordinary wage for a good mechanic being about £4 per week; the workshop may consist of a room in a basement or attic furnished with a second-hand lathe, blow-pipe, &c., with a few old saucepans and other household articles adapted for the purpose. At the same time the operation room may be very unsatisfactory; I saw some time ago in London, an unregistered dentist whose operating room reminded me of a fifth-rate barber's shop. The syringe used for local anæsthetics was lying on a dirty towel, and likely to be a serious danger to anyone for whom it was used. It would be much better if these places were more under the public eye, but in ordinary circumstances real coöperative effort could only be provided either through local authorities or by something in the nature of a company, and as the law is very wisely regulating companies engaged in dental practice, owing to scandalous abuses in the past, the formation of a company for the supply of efficient dental service presents serious difficulties. It is, however, being done at Bournemouth and at other places, as I have already mentioned. The following figures taken from the annual report of the Bournemouth and District Dental Clinic for 1921 are of interest. There are 23 dentists serving the clinic; fees were £2281 8*s.* 3*d.*, expenses £1080 11*s.*, and the amount for division among the dental staff £1233 0*s.* 8*d.* Other figures during 1920 were: patients' attendances, 4029; new patients, 1045; extractions, 4526; fillings, 818; dressings, 218; dentures 286; local anæsthetics, 436; major anæsthetics, 16; repairs, 88; scalings, 102; impressions and bites, 638. I am informed by the secretary that since the passing of the Dentists Act of 1921 the dental practitioners of the Bournemouth clinic are considering the advisability of adopting the panel system instead. If all the dental effort in a locality could be concentrated in one small area, such as a clinic, and mechanical work pooled on a coöperative basis among efficient mechanics working for several dentists, in well-equipped workshops supplied with up-to-date machinery, it would be very much better than it is now with the wasteful and inefficient methods adopted in many dental surgeries of to-day.

Dr. Sidney Barwise, county medical officer, Derbyshire, has suggested the employment of dental dressers, under the immediate supervision of qualified practitioners, for simpler forms of treatment, especially for school-children. Under proper safeguards, with a shortage of dentists and a desire to economise, such a system has much to recommend it—e.g., for dental schemes under public authorities or in such clinics as those mentioned above—but as a number of persons who are being admitted to the Register are incompetent to supervise or to teach such a system would be capable of very great abuses.

The association of dental and medical services presents important economic considerations. In the past, registered medical practitioners have been prohibited from coöperating with unregistered dentists in the practice of dentistry. Now, of course, medical practitioners may render assistance to what were previously unregistered dentists who have become registered; this fact will enable general anæsthetics to be given more frequently than in the past. Most of the general anæsthetic work of unregistered dentists consisted in the administration of nitrous oxide "at arm's length"; they were afraid of giving too much, and as a rule they gave too little. In the Registrar-General's report for 1920 six deaths under anæsthetics are regarded as due to operations on the teeth and gums. Unregistered dentists made considerable use of local anæsthetics which in many cases caused a considerable amount of trouble owing to their lack of surgical cleanliness. It would be of great benefit to the public if some of the older and less skilful dentists would give up operative dentistry, and devote their attention entirely to mechanical work, a division of labour which exists to a considerable extent in Canada—the two branches of the profession there, operative and mechanical, being more or less separate.

Many of us would have liked to have seen the registered dental practitioner a surgical specialist, devoting his attention to one part of the body, but owing to the quality of a large number of persons admitted to the Register, this policy has not been followed; now that such specialised treatment as X ray examinations and the preparation of vaccines are becoming regularly recognised as part of dental treatment, the ordinary registered practitioners should be prepared to seek in consultation the assistance of other persons, dentists or doctors, who have had considerable experience in these branches of work, a combination of effort met with very little in the past. The necessity for this coöperation would increase the advantages to be derived from dental clinics.

The Government is now presenting a number of imperfectly educated dental practitioners with a monopoly value, the cost of which in future will be about £1000 a head. The public may reasonably expect a certain standard of efficiency on the part of the newly-registered, and it would be an advantage to follow the practice of the Central Midwives Board, who, after allowing midwives reasonable time to improve their methods, have removed from the registers the names of persons proved after complaint to be incompetent. The Government formerly only provided for the inspection of the work of public vaccinators and gave grants for the promotion of their efficiency if the work was well done. As in some cases exception has had to be taken to the performance of this very simple operation, it seems reasonable to expect that other work of both doctors and dentists should be supervised. Unskilful work by a dental practitioner may have very serious consequences indeed; work in which the State provides part of the cost of treatment should be supervised, and some system of local supervision should be instituted at once. Some one should be charged with the duty of making complaints to the Dental Board in suitable cases. Medical officers of health should be required to report any case of irregularity observed in their areas to the Dental Board, and should be protected in the discharge of their duty. The requirements of the 1918 Education Act should be enforced as soon as possible—i.e., that all education authorities shall provide proper dental service for their school-children, that this service should be available for children under 5 and for women coming under maternity and child welfare schemes, and that all approved societies shall take part in the work of the National Beneficent Society, or in some other way provide for dental service for all their insured members. This provision would at once include children and wage-earners, but would leave out a large number of single women, and married women who are not recent or prospective mothers, who should be provided for by a public dental service either on the lines of the clinics mentioned at Bournemouth, &c., or through the local authorities, on the analogy of water-supply or education service—i.e., because it is impossible for the majority of people to obtain it except in a proper coöperative basis. The cost of the services might be paid wholly or partially by the patients, except in cases of necessity, when similar measures could be adopted to those used for payment of the fees of doctors called in emergency by midwives. A useful preliminary to such a service would be to take the treatment of sick out of the Poor-law, hand it over to county and county borough councils, and thus provide in the area of these authorities an adequate institutional medical service which could include a public dental service. Bradford has provided a useful precedent; there the Poor-law hospital has been recently taken over by the city council, and supplies special treatment efficiently and at a no greater cost than when it was administered by boards of guardians under the disadvantages of association with other Poor-law work and without the advantage of a specialist staff.

In this short paper nothing has, of course, been said about dental research or recruiting new members for the dental profession, but the present is an opportune time to consider the importance of dental surgery and to regulate the work of dental practitioners. It was recently calculated that sickness costs this country about 150 millions per annum, but the Geddes Committee made no suggestion for effecting any economy to diminish expenditure of this vast sum. We cannot afford to waste money in this way in addition to perpetuating unnecessary suffering and death by failure to deal with questions of public health. It is suggested that the provision of a public dental service would effect appreciable economies in this direction and that the money spent on it would be a good investment.

CONDITIONS OF HEALTH IN THE BOOT AND SHOE TRADE.

THE boot and shoe trade forms one of the staple industries of the city of Norwich, and some interesting facts and suggestions as to the health of shoe operatives were brought out by Dr. F. W. Burton-Fanning in a lecture recently delivered to the Norwich Shoe Trade Managers' and Foremen's Provident Association. Dr. Burton-Fanning said that he had been invited to visit several factories and make any investigations he wished. He noticed a great improvement as regards buildings, hours, pay, and interest taken by employers in their employees since his previous visit some years ago, but there was still room for improvement.

Tuberculosis.

The only disease from which shoemakers suffered unduly as compared with the ordinary population was tuberculosis of the lungs, which was very prevalent amongst them. While 100 males of all occupations died from consumption, 145 shoemakers died of that malady; for 100 deaths of clergymen from the disease there were 456 deaths of shoemakers. The death-rate from pulmonary tuberculosis in one year per 1000 living persons was: Agriculturists 1·02, engineers 2·36, clerks 3·20, tailors 4·12, and shoemakers 4·41. Figures in Norwich confirm the story.

During the seven years in which sanatorium benefit was administered by the Norwich Health Insurance Committee, of 439 males applying for treatment 33·5 per cent. were occupied in boot factories, and of 297 women applying for treatment 20·2 per cent. were similarly occupied. Causes for this excessive incidence of consumption among shoe operatives had been, he said, suggested: (1) Poverty, with consequent bad housing and poor feeding; but agricultural labourers, who are far worse paid and often worse housed, suffer much less from consumption. (2) Excessive drinking; but the Registrar-General has shown that shoe operatives die from alcoholism to a less extent than the average population. (3) The odour from leather has been shown to have no particularly harmful effect on health, neither is the dust of boot factories possessed of any specially deleterious qualities; also, most factories are aware of the importance of avoiding dust and how to deal with it. (4) The cramped position of the shoemaker. Dr. Burton-Fanning did not think this less marked nowadays than formerly, or regard it as a contributory cause. But he believed that want of exercise played some part; it had been suggested that the more sedentary forms of work are associated with a higher consumptive death-rate, but probably the less robust members of the population were attracted to shoemaking because little muscular effort is demanded by the work.

Fatigue, nerve strain, and speed of work had a good deal to answer for, largely on account of the lack of fresh air in the factory rooms. Operatives who contracted tuberculosis were apparently distributed fairly evenly amongst all the factories of Norwich, and in Dr. Burton-Fanning's opinion its incidence was due, not to direct infection in the factories, but to the lowering of the operative's resistance to the growth of the organisms of the disease, implanted in him in childhood by the conditions of factory life. He thought that the want of fresh moving air was the most important cause of consumption in boot factories. The average age at death of all agricultural labourers who work in the open air was 66 years, and that of men employed in factories was 45 years.

For the boot factory operative who developed consumption there was the sanatorium, where the malady is usually checked by proper treatment, but experience showed only too plainly that the ex-sanatorium patient was not fitted to resume his place in the factory and keep pace with other workers at his old trade. For these men there was now a colony at Stanninghall, five miles from Norwich. This colony was started by Red Cross Funds for tuberculous soldiers, but civilians were now also admitted. To some extent outdoor occupations, such as market gardening and the tending of poultry and pigs, are followed, but it was found that the trade in which the man is already skilled provided him with the best living, and therefore industries were developed to allow colonists to resume their former employment. The prevalence of consumption in the boot and shoe industry had been the subject of a special investigation promoted by the Medical Research Committee, and it had been suggested that a boot and shoe factory should be started with ex-sanatorium operatives.

Lack of Fresh Air.

Coal-miners worked as a rule in well-ventilated shafts, using a great deal of muscular effort and clothing themselves lightly; whilst 70 per cent. of the miners who presented themselves for the army were graded in Class A, only 36 per cent. of industrial workers were so classed. Of all the workrooms in the factories which he had recently visited, he only found one room which wholly complied with requirements in the matter of fresh air. In this room there were only two workers, one of whom appreciated the virtues of fresh cool air, and had no opposition to contend with from others. The want of fresh air in all other rooms was immediately perceptible to the senses, and the striking contrast between the air of the workroom and that out of doors was a sufficient criterion. Observations were taken with Prof. Leonard Hill's kata-thermometer, and in only one room were the readings of the wet and dry bulb satisfactory in regard to the state of the atmosphere in which the men and women were working. In all the other rooms there was shown to a greater or less extent a want of cooling and evaporative power of the air. Thanks especially to the work and writings of Prof. Hill, it was now understood how stuffiness comes to be harmful and why fresh air possesses certain virtues. If the air was too still and too warm our vital processes concerned in heat production and the maintenance of bodily temperature were suppressed, with injurious effects on both our physical and mental welfare. Sweating had been described as "Nature's emergency mechanism for heat loss," and managers in factories should appreciate that to allow the air of workrooms to induce sweating in the workers, as he had found to be the case in several rooms on a winter's day, was to have their hands working under conditions of unnecessary and harmful strain. The free opening of properly arranged windows was the way to secure the right conditions for the workers—viz., cool and moving air. The temperature of the rooms should not be as low as 55° F., for it had been found that this degree of cold was associated with increased risks from accidents due to numbing of the hands. Short of this, the cooler the air the better for the workers, and on no account should a temperature of over 63° be approved of. The proper supply of fresh air by the opening of windows rests, Dr. Burton-Fanning said, with the prejudices of the workmen. Their objection was mainly due to ignorance, and to their rooted belief that cold is the cause of all ills. Even the infection of a wound was ascribed by ignorant people to cold; they failed to appreciate that germs disliked cold more than we did. Every effort should be made by the medical profession to convince workmen that their toil cost them less exhaustion in good air, and that the skin readily adapted itself to lower temperatures. Draughts were not to be recommended, but they did not occur in a properly ventilated room.

In conclusion, Dr. Burton-Fanning said that as such a large proportion of colonists from Norwich were expert operatives, he was most anxious to start a model factory for them, and suggested that such an enterprise might be grafted on to the existing colony at Stanninghall.

THE SALARIES OF WHOLE-TIME MEDICAL OFFICERS.

THE Southampton Borough Council recently sent an advertisement to the medical papers inviting applications for an appointment as whole-time school dentist at a salary of £450 rising to £540, and for the post of assistant medical officer at £450. *The Lancet* and the *British Medical Journal* both replied that they could not accept advertisements offering less than £500 per annum for either post. The Health Committee of the council thereupon recommended advertisement at that figure.

At the meeting of the borough council on Jan. 3rd, Mr. P. V. Bowyer asked what things were coming to. Was the council to be dictated to by newspapers as to what it was to pay its officials? It was intolerable. The two papers sought to say that £500 a year was to be the minimum a dentist was to receive the moment he left college. He was just qualified and no more, and had never pulled out a tooth for profit.

A voice: But he has for pain.

"You may talk about trade-unionism among workmen," added Mr. Bowyer, "but the trade-unionism among members of the medical profession is getting beyond anything."

Alderman Kimber said it was time the council ceased to allow other people to dictate to it. Were they going to be fooled about by *The Lancet*? He did not like the name of that paper. He moved an amendment that the positions be readvertised in non-medical papers at £450 a year.

Mr. H. M. Pugh (a solicitor) seconded. The council had, he said, decided on a 10 per cent. cut of wages and salaries, but the attitude of the Health Committee was that those who were protected should not have a reduction at all. It had been said that the borough electrical engineer was the only chief official of the corporation who was a trade-unionist, but the trade-unionism of the doctors was far stronger. Many a young solicitor would jump at an offer of £450 a year.

Mr. Silverman said he did not see why the council should be blackmailed by professional cliques.

The Mayor: I wouldn't say blackmailed.

Mr. Silverman: Well, I do say it.

A Labour member expressed surprise at Mr. Pugh's attitude. In another connexion Mr. Pugh would not take the same stand. They all knew what would happen if the Health Committee appointed a man in opposition to the views of the medical profession, and he doubted very much whether they would get applications from reliable men.

Dr. E. H. M. Stancomb said that the people who were opposing the minimum salary which the medical men thought right would not cavil at any price for saving themselves or any members of their families. The papers named had decided that for the preservation of the public and the dignity of the profession they would not take advertisements offering salaries below the minimum ones.

The council decided to advertise the unamended salaries in lay papers.

THE PROLAPSUPORT.

WE have received from Messrs. Allen and Hanburys, Ltd., 48, Wigmore-street, London, W., an ingeniously constructed uterine support which, it is claimed, may be inserted, adjusted, removed, and cleansed by the patient herself as often as may be necessary. It is made of rubber, mushroom-shaped, with a long stem the distal end of which is expanded into the form of a funnel. This funnel-like projection extends outside the vagina and its purpose is to protect a screw nut which, acting on a rod passing through the stem of the appliance, causes, on being turned, the supporting part of the pessary to assume the form either of a flattened sphere—the pessary proper—or a collapsed bulb thus facilitating insertion or removal. When inserted and adjusted it is said to make a suitable support for the uterus and to retain it well in position. The instrument is made in two sizes and the price is £1 5*s*.

A FRENCH MEDICAL DIRECTORY.

THE new edition of "Medicus" (Guide-Annuaire des Etudiants et des Praticiens." Paris: A. Rouzaud. 1923. Pp. 1563+xxxi.) is shorter by some 150 pages than its predecessor of 1922, but nothing has apparently been lost in the process of condensing this well-known medical annual. Part 1 of the volume is devoted to the organisation of the medical profession in France and to the facilities for and regulation of medical education in Paris. Part 2 deals with provincial faculties and schools of medicine, and Part 3 with foreign schools of medicine. Part 4 consists of a "Dictionnaire de droit et de jurisprudence médicale" for the use of medical men. Part 5 contains the laws and decrees relating to the practice of medicine and pharmacy in France, including those devoted particularly to tuberculosis, public health, industrial accidents, &c. Part 6 consists of a directory of the entire French medical profession, listed alphabetically and geographically, under four headings: Paris, Seine, Departments, and Colonies. It is announced that the usual supplements will be issued during the forthcoming year. An editorial note invites readers to point out errors in the text of "Medicus"; we may, therefore, state that the reference to this journal in the list on p. 412 should read as follows: *The Lancet*, 423, Strand, Londres, W.C. 2.

THE RELIEF OF DISTRESS.

"The Prevention and Relief of Distress" is the title of a handbook [1] of information relating to the statutory and voluntary means available for the relief of distress and the improvement of social conditions—a handbook which is in fact Sir Charles Loch's "How to Help Cases of Distress" rearranged, brought up to date, and re-issued by the Charity Organisation Society. The object of its publication is to place in the hands of the social worker or student such detailed information under various headings as ought to be possessed by persons who undertake the responsibility of relief administration. The handbook, therefore, describes the principles which underlie such administration, and the methods shown by experience to be sound. Although written from the standpoint of the London worker, its contents will be of great use to workers elsewhere. The chapter headings sufficiently indicate the range of subjects: they are as follows: The Framework of Local Government in London; Poor-law Administration; Principles and Methods of Charity; Distress Due to Sickness; Distress Due to Mental or Physical Disability; Distress Among Persons of Particular Age, Class, or Condition; Unemployment; Distress Arising out of the War; Special Classes not included in the foregoing list; Rescue Work; and Endowed Charities.

COLONIAL HEALTH REPORTS.

Straits Settlements.—In his report for 1921 Mr. F. M. Baddeley, acting Colonial Secretary, states that the population, as enumerated at the Census on April 24th, comprised 557,838 males and 324,101 females—total 881,939, distributed amongst the Settlements as follows: Singapore, 417,859; Penang, 304,572; Malacca, 153,599; Labuan, 5909. The total was made up of 8045 Europeans and Americans, 9015 Eurasians, 254,843 Malays, 497,406 Chinese, 104,498 Indians, and 8132 other nationalities. The Chinese population had increased, since the previous Census, 34·9 per cent.—the males by 24 per cent. and the females by 65·2 per cent.; the increase in Chinese females was the outstanding feature of the Census. The crude birth-rate in 1921 was 32·57 per 1000, the percentage of males born being 52 to 48 females. The crude death-rate was 31·79 per 1000. Deaths from pneumonia numbered 1702, from influenza 262, from beri-beri 1272, from malarial fever 4707, from tuberculosis 3292, from dysentery 1081, and from diarrhœa 359. Dangerous infectious diseases notified in the colony did not play a large part in the mortality. There were 62 deaths from cerebro-spinal fever, 28 from plague, 2 from cholera, and 47 from small-pox. All but 6 of the deaths from small-pox occurred in Singapore, where the disease was prevalent from May until the end of the year, the total of cases there being 147.

Bermuda.—The total population, according to the Census held in April, 1921, was 22,505, including the naval and military establishments (1536) and the hotel floating population (842); the white population numbered 7006 and the coloured 13,121. The birth-rate in 1921 was 31·2 per 1000 (25·7 white and 34·2 coloured). The death-rate was 18·37 per 1000 (15·55 white and 19·46 coloured). Illegitimate births were 14·6 per cent. (7·1 white and 13·5 coloured) of the total. The Public Health Act, 1920, was put into force on March 1st, 1921, when Dr. Eugene Walker assumed duties as medical officer of health. This Act, taken in conjunction with the Pest Destruction Act, 1921, sets up all the machinery necessary for the more scientific and efficient handling of the many sanitary and cognate problems connected with the preservation of the public health, which, speaking generally, continued to be excellent in 1921. There are no tropical diseases other than an occasional mild type of fever diagnosed as dengue. Malarial fever is unknown. During the summer months there was a sporadic but mild type of typhoid fever, 54 cases in all resulting in three deaths. There was also a somewhat severe epidemic of measles and whooping-cough during the year. There were 28 deaths from tuberculosis—six less than in 1920. The great majority of houses have a good water-supply, each house having its own rain-water cistern, and typhoid infection is therefore rarely spread through an infected water-supply. The most serious sources of infection are from flies, and the inadequate sanitary conveniences available in many of the poorer dwellings. A start has been made with the campaign against mosquitoes. The equable nature of the climate generally is most agreeable, and is no doubt mainly responsible for the satisfactory state of the public health. In 1921 the mean temperature was 67·5° F. in January and April, 77·9° in July, and 70·9° in November. The total rainfall was 54·43 inches. About 17,000 tourists are estimated to have visited the colony during 1921. These figures really cover part of two seasons, as the "season" runs from November in one calendar year to the end of April or May in the next. Summer travel seems likely to increase largely in the near future.

DIETETIC HINTS.

MOST writers on food advocate a return to a more natural diet, but fail to tell us why nature has provided us with an appetite beyond our needs; thus their claim that we all eat far too much falls rather out of line with their general argument. A recent volume entitled Diet for Women,[1] by Dr. Cecil Webb-Johnson, contains sense and not, we think, nonsense. The author condemns milk as a food; but the argument that cow's milk was not intended for human consumption, and that the composition of a calf's body is different from an infant's, is illogical, and might be applied to any article of diet other than human flesh or human milk. The author gives some useful help in the choice of foods, and in discussing alcohol and tobacco. From the standpoint of accuracy the book has lapses A writer who refers to the greatest name in medicine as "John" Harvey, states baldly that it is generally agreed that both physiologically and anatomically man is intended by nature to be a fruit-eating animal, and that the pulse-rate is ten beats per minute faster in meat-eaters than in vegetarians does not command our confidence; but this is no reason why his manual should not be interesting and witty, and it is both.

SURGICAL INSTRUMENTS: A CHANGE OF ADDRESS.

WE are informed that the well-known surgical instrument business of Arnold and Sons, of 6, Giltspur-street, London, E.C., recently acquired by Messrs. John Bell and Croyden, Ltd., has been transferred to new premises adjoining the latter's pharmacy at 50 and 52, Wigmore-street, W. A repair department is now open; an emergency cabinet from which instruments may be borrowed, and a large dispensing department, are both accessible to members of the medical profession at all hours of the day and night.

ANILINE PENCIL IN A BUN.

To the Editor of THE LANCET.

SIR,—Your reference to a case of tissue-necrosis caused by a coloured pencil, reported by Dr. E. Glass, of Hamburg, strikes a timely note of warning when aniline pencils are in such common use. About 15 years ago a man called upon me in a terribly excited state, his tongue protruding and purple saliva dribbling from his mouth. After his mouth had been thoroughly washed out I was told that when eating a bath-bun he had recently bought he felt a gritty substance between his teeth which he speedily ejected. He was, however, alarmed at the deep purple colour, not only of the matter ejected, but also of the deep staining of the mouth and lips. As the patient seemed to be none the worse except for the staining I dismissed him and advised him to see his doctor if any symptom arose. I think there can be no doubt that a piece of an aniline pencil had accidentally got into the bun.

I am, Sir, yours faithfully,
CHARLES W. CHAPMAN.
Harley-street, W., Jan. 2nd, 1923.

THE CHAULMOOGRA PLANT IN LEPROSY: AN ANCIENT REMEDY.

To the Editor of THE LANCET.

SIR,—An ancient story current in India credits the Chaulmoogra plant with being one of the oldest known remedies in the treatment of leprosy. This legend is at the moment rather absorbing, connecting a fragment of the early history of medicine in India with the most up-to-date medical research. Rama, a king of Benares, was afflicted with leprosy, relinquished his throne in favour of his son, and disappeared into the jungle, in which he lived on roots and herbs, and especially on the leaves of the kalaw tree; he eventually recovered completely. One day he accidentally met the Princess Piya in the jungle; she had been banished from the kingdom of her father; also on account of suffering from leprosy. Rama effected her cure by feeding her on the fruit, root, and leaves of the kalaw tree, married her, and erected a new city in the place where these trees grew. The lady by way of showing her gratitude presented the devoted Rama with twin sons on 16 occasions—so the story goes.

Chaulmoogra oil is obtained from the kalaw tree, and it has been in use in India for centuries as a remedy for leprosy and several skin diseases. To-day, thanks to the work of Sir Leonard Rogers, the ethyl asters of the acids from chaulmoogra oil are yielding results far more satisfactory in the treatment of leprosy than any remedy hitherto employed in that disease. These asters are being used in the eight leper asylums in the Province of Bihar and Orissa, which in 1921 contained 1967 resident lepers; the reports on this treatment in these institutions are most encouraging.

I am, Sir, yours faithfully,
P. HEHIR,
Westward Ho! Dec. 26th, 1922. Major-General, I.M.S. (ret.).

An Address

ON

ACHLORHYDRIA:

ITS RELATION TO PERNICIOUS ANÆMIA AND OTHER DISEASES.

Delivered at the Hôpital Saint-Michel, Paris, on Oct. 30th, 1922.

BY ARTHUR F. HURST, M.D. OXF.,
F.R.C.P. LOND.,
PHYSICIAN TO GUY'S HOSPITAL.

IN my former lecture* I attempted to show how the "hypersthenic gastric diathesis," one manifestation of which is hyperchlorhydria, predisposes to the development of duodenal ulcer. To-day I propose to speak about its direct antithesis—the "achlorhydric gastric diathesis," in which the mucous membrane of the stomach, owing to some obscure congenital deficiency, secretes no hydrochloric acid. Some authors have denied the existence of primary or constitutional achlorhydria, believing that all cases are secondary to chronic gastritis. Though I am convinced that this view is incorrect, the matter is not one of fundamental importance, as the physiological and pathological results of achlorhydria are identical whether the condition is primary or secondary; I shall therefore have to discuss the results of the acquired condition at the same time as that of the congenital abnormality. An understanding of the pathogenesis of achlorhydria is, however, important, as it enables us to decide whether in a given case the condition is likely to be permanent, and what treatment is likely to be most satisfactory. But the effects of achlorhydria on digestion and on the body as a whole are largely independent of its cause, as the same sequels may occur whether it is primary and congenital, secondary to chronic gastritis or other local disease, or a sequel of a gastro-enterostomy or gastrectomy.

ACHLORHYDRIA OR ACHYLIA GASTRICA.

When I speak of achlorhydria I mean a condition in which no free hydrochloric acid is present when fasting and in which none appears throughout the period of digestion. The introduction of the fractional test-meal has greatly increased the accuracy with which this can be recognised. We have found that it is not at all uncommon for free hydrochloric acid to be completely absent from the gastric contents an hour after a meal, and yet to be present in small quantities, and occasionally even in large quantities, at some other period of digestion. Thus out of 325 consecutive fractional test-meals performed at New Lodge Clinic complete achlorhydria was present in 34 (10·5 per cent.) cases; free hydrochloric acid was absent from the one-hour fraction in 30 (9·2 per cent.) additional cases, in 22 of which it was also absent from the resting-juice and from the three-quarter hour fraction, although free acid was present at other times during the test-meal—15 times in normal amount and once actually in excess. In the additional 9·2 per cent. of cases the old-fashioned one-hour test-meal would have led to a diagnosis of achlorhydria, whereas the fractional method showed that free acid was actually present either in subnormal, normal, or even excessive quantity, but that its first appearance was delayed. Thus the frequency of what is diagnosed as achlorhydria is much less than the old method would indicate. This is particularly well seen in the case of cancer of the stomach, in which achlorhydria is found in about 80 per cent. of cases by the old method (Hayem and Lion), but in only about 50 per cent. by the new (Hartman).

The discovery of complete achlorhydria does not necessarily indicate that no gastric juice containing hydrochloric acid is secreted, as small quantities of acid may be completely neutralised by the alkaline saliva and food. Moreover, in most cases of achlorhydria some pepsin is present in the gastric contents. Achlorhydria is therefore not synonymous with achylia gastrica, which is very rare in comparison. Achlorhydria has the same effect on digestion whether it is due to actual achylia or not, and, as it is also more readily recognised, for practical purposes a diagnosis of achlorhydria is sufficient, and the term should be employed in preference to achylia unless actual investigations have proved that no trace of hydrochloric acid or pepsin is secreted by the gastric mucous membrane.

CHRONIC GASTRITIS AS A COMPLICATION OF PRIMARY OR CONSTITUTIONAL ACHYLIA GASTRICA.

Quite apart from its specific activities, the gastric juice softens any hard and dry particles of food which reach the stomach as a result of insufficient mastication, and dilutes such chemical irritants as alcohol which may reach it in a too concentrated form. The achylia gastrica, which is an inborn error of function unconnected with any organic change in the stomach, is thus likely sooner or later to be complicated by chronic gastritis. As it frequently gives rise to no symptoms of any kind, the individual receives no warning that he must be exceptionally careful to chew his food thoroughly, to avoid mechanical and chemical irritants in his diet, and to avoid swallowing very hot or very cold food or drink. By the time that obvious symptoms have developed, and still more so by the time that death occurs from some secondary or independent disease, the gastric mucous membrane shows obvious changes. This, I believe, is the true explanation of the pathological observations of Faber[1] and others, who have found evidence of chronic gastritis and often of atrophy of the mucous membrane after death in most cases of achylia. They interpreted this as indicating that achylia is always secondary to chronic gastritis, although the pathological changes are often slight and patchy, large areas with normal-looking glands being present, so that there can be no question of the achylia being due to actual destruction of all the secreting tubules.

I believe that it is much more common for the gastritis to be secondary to the achylia. When gastritis is primary—as it undoubtedly is in the achlorhydria of alcoholics, which is often associated with cirrhosis of the liver—recovery frequently occurs if the source of irritation is removed. Thus I have several times observed a return to the normal gastric secretion after alcoholic patients have been deprived of all alcohol and kept on a light diet for a few weeks. On the other hand, the majority of cases of achlorhydria, in which no obvious primary source of irritation is present, show no change in their gastric contents, even after prolonged treatment with careful diet and suitable drugs, although all symptoms may have disappeared for a long period. Thus a lady who consulted me in 1913 for nausea was found to have complete achlorhydria. She lost her symptoms on taking hydrochloric acid. In 1920 she consulted me for nervous symptoms; she had had no nausea or other digestive disturbance for seven years, but complete achlorhydria was still present. In her case I feel convinced that the achlorhydria was a congenital abnormality, and any sign of inflammation or atrophy which might be discovered on microscopical examination of her gastric mucous membrane would, I believe, be due to the permanent loss of the protection from mechanical and chemical irritants normally afforded by the softening and diluting action of the gastric juice. Primary achylia gastrica does not depend upon any anatomical peculiarity, as fragments of gastric mucous membrane, which I have had removed during an operation for appendicitis in patients with this condition, have generally looked perfectly normal and have always shown the usual number of healthy-looking oxyntic cells. It must therefore be due to an inborn deficiency in the functional capacity of glands, which appear to be structurally normal.

---

* THE LANCET, 1922, ii., 1369.

The Digestive Functions of Gastric Juice.

The specific functions of the stomach are two-fold—digestive and antiseptic. The digestive function consists in the chemical and physical preparation of the food which reaches it from the mouth for digestion in the intestines. The antiseptic function consists in partial destruction of organisms originating in the mouth, nose, or naso-pharynx, or introduced in food or drink.

The chief digestive function is the partial conversion of proteins into simple bodies by the action of pepsin, which is only active in the presence of free or organically combined hydrochloric acid. The other ferments of the gastric juice are of comparatively little use, but the softening action of the hydrochloric acid on connective tissue, which was first emphasised by Adolf Schmidt, is an important function, as it disintegrates meat and permits the gastric and pancreatic juice to act upon the protein and fat. As the secretin formed by the action of hydrochloric acid on the prosecretin present in the duodenal mucous membrane was shown by Bayliss and Starling to be an important stimulant of pancreatic secretion, it might be expected that achylia gastrica would lead to achylia pancreatica. This is not, however, the case, though curiously enough severe pancreatic disease, in which little or no pancreatic juice is secreted, is almost always associated with achlorhydria. Presumably the psychical and the other chemical stimuli of pancreatic secretion are sufficiently powerful to cause an adequate flow of juice in the majority of cases.

In the absence of the normal gastric secretion food enters the duodenum in much the same state as that in which it is swallowed. If the individual eats slowly and chews thoroughly, any mechanical and thermal irritation the food might exert will be lost in the mouth, and any chemical irritants it contains will be diluted by the saliva, so that it is not likely to damage seriously either the gastric or intestinal mucous membrane. But if it is bolted, or if mastication is inefficient owing to want of teeth, the food will have the same deleterious effects on the duodenal mucous membrane which I have already mentioned in connexion with the stomach, though the rest of the intestine will be protected by the diluting action of the bile and the pancreatic and intestinal juices. The saliva cannot, however, in any way compensate for the loss of the softening effect of the hydrochloric acid on connective tissue and the digestive action of pepsin on proteins. Consequently in all cases of achlorhydria much completely undigested food will reach the duodenum. Although pancreatic digestion is in most cases sufficient to do the work of the gastric juice in addition to its own, protein digestion in the intestine will be considerably delayed, and a larger quantity than normal is likely to reach the cæcum in an incompletely digested state, so that there will be a plentiful supply of only slightly altered protein available for bacterial decomposition in the colon. Achlorhydria is frequently latent, being discovered accidentally in people with no obvious digestive symptoms. When symptoms occur, they are due chiefly to the irritation of the small intestines by food inadequately prepared in the stomach. To this is often added irritation of the colon by products of abnormal bacterial activity owing to the supply of incompletely digested proteins being excessive, and to the excessive number of bacteria likely to reach it because of the absence of the normal antiseptic action of the gastric juice.

Intestinal Dyspepsia Following Gastro-Enterostomy.

The digestive symptoms which may follow a gastro-enterostomy, apart from the development of a gastro-jejunal or jejunal ulcer, are of a precisely similar nature to those caused by primary achylia gastrica, being due to the passage into the jejunum of food which has not undergone the necessary mechanical and chemical preparation in the stomach owing to its rapid evacuation, and to the absence of free hydrochloric acid, which frequently follows the operation unless it is performed for a duodenal ulcer, when the hyperchlorhydria generally persists (Conybeare).[2]

Association of Achlorhydria with Appendicitis and Cholecystitis.

The majority of people with pyorrhœa alveolaris are none the worse for the large quantity of infective pus they are constantly swallowing, as the bacteria are to a large extent destroyed by the antiseptic action of the hydrochloric acid of the gastric juice. But out of each hundred normal people about four have constitutional achylia gastrica (Bennett and Ryle[3]), and presumably the same proportion of otherwise healthy individuals with pyorrhœa alveolaris, or chronic infection of the tonsils, nose, or naso-pharynx, have achylia. So long as the mucous membrane of the stomach and intestines is intact and no abnormal degree of stasis occurs in any part of the alimentary canal, the bacteria, which gain access to the stomach and, owing to the loss of the antiseptic action of the gastric juice, pass in undiminished numbers into the intestines, do not invade the mucous membrane. But the excess of streptococci constantly present in all parts of the alimentary canal may seriously aggravate any pathological condition already present. It has, for example, been shown by Rosenow that appendicitis and cholecystitis are probably always secondary to hæmatogenous infection, and that the same streptococci isolated from the teeth or tonsils of a case of appendicitis or cholecystitis, which give rise to inflammation of the appendix or gall-bladder when injected into the veins of animals, have no such effect when introduced in large quantities into the lumen of the appendix or gall-bladder respectively. When, however, the mucous membrane of the appendix is once damaged or the free flow of its contents is impeded by the presence of fæcolith or as the result of a stricture or kink following a previous attack of appendicitis, secondary infection from the lumen may occur and give rise either to an attack of acute appendicitis or to chronic appendicitis. The same thing may happen in connexion with the gall-bladder after its mucous membrane has once become damaged. I have long been struck by the comparative frequency of achlorhydria in patients suffering from chronic appendicitis, and T. G. D. Bonar[4] has recently found that 33 per cent. of 65 cases operated upon for this condition at Guy's Hospital had very little or no free hydrochloric acid in their stomach throughout the course of a fractional test-meal. I believe that the hyperchlorhydria which was present in 55 per cent. of Bonar's cases must be a reflex result of the appendicitis, but I cannot see how the achlorhydria can also be secondary. It seems more probable that primary achylia gastrica predisposes to chronic appendicitis by helping to maintain or to aggravate an infection which is primarily hæmatogenous, by permitting the access into the lumen of the appendix of excess of oral streptococci, which in a normal individual would have been destroyed to a large extent by the gastric juice. The proportion of patients with gall-stones who have achlorhydria (49 per cent.) and hyperchlorhydria (23 per cent.) was also found by Bonar to be greater than normal, and I believe that this is due, as in the case of appendicitis, to the former predisposing to ascending infection, whilst the latter is a reflex result of the primary gall-bladder disease.

Achlorhydria and Rheumatoid Arthritis.

Rheumatoid arthritis is, I believe, invariably secondary to focal infection. In most cases this is primarily in the teeth, the removal of which will lead to the rapid cure of most early cases of the disease. Not infrequently the tonsils are also infected and require removal, and occasionally other foci, such as the nasal sinuses, require treatment. But in some severe cases, though temporary improvement follows the removal of these foci, the disease is not completely arrested. It is then usual to find that the intestines are also infected, presumably from swallowed organisms, the intestinal infection being secondary to that in the mouth. A remarkable proportion of these cases have complete achlorhydria. Thus Faber[1] found achylia gastrica in 15 out of 65 cases of chronic polyarthritis. About four out of every hundred patients who develop rheumatoid arthritis presumably have congenital achylia gastrica. They are extremely likely to develop intestinal infection secondary to their oral sepsis; the treatment of the latter will therefore not lead to their cure. If, for example, ten out of the hundred patients referred to do not recover after the oral sepsis has been eradicated, four of them—or 40 per cent.—are likely to have achlorhydria. The latter is, of course, not an essential predisposing factor in the development of secondary intestinal infection, but it is certainly a very powerful predisposing cause. A test-meal should therefore be given in all cases of rheumatoid arthritis, and, if achlorhydria is found, full doses of hydrochloric acid should be given, as well as sour milk, and perhaps a vaccine prepared from streptococci isolated from infected teeth and the intestinal contents.

ACHLORHYDRIA AND ADDISON'S (PERNICIOUS) ANÆMIA.

It has long been known that Addison's (pernicious) anæmia is almost invariably associated with complete absence of free hydrochloric acid from the gastric contents when examined after an ordinary test-meal. Recent investigations have shown that this absence of free hydrochloric acid invariably persists throughout the whole period of digestion when investigated by the fractional method. I have already pointed out that it is not at all uncommon to find a small quantity of free acid and occasionally even a larger quantity in one or more of the fractions when the resting juice and the contents removed at the end of three quarters of an hour or an hour or both contain none, but this is never the case in Addison's anæmia.

It has been suggested that the achlorhydria is secondary to the anæmia. But there is abundant evidence that the achlorhydria precedes the development of the anæmia. As Robert Hutchison[5] first pointed out, there is generally a more or less long history of digestive disturbance, of the type which may result from uncomplicated achlorhydria, preceding the first symptoms of anæmia. In one case achlorhydria has actually been discovered 12, in two others 10, and in others 8, 7, 6, 5, 3 (two cases), and 1 year (twice) before the onset of anæmia. If achlorhydria were secondary to the anæmia or even if it were secondary to gastritis produced by the same toxin as that which caused the anæmia, cases would occur in which normal gastric secretion could be observed giving place to hyperchlorhydria and finally to complete achlorhydria as the disease progressed. Such a sequence of events has often been demonstrated in cancer of the stomach and also in phthisis. But at whatever stage in the development of the anæmia the examination is made, achlorhydria is found. It was present, for example, in cases in which the hæmoglobin percentage had not fallen below 85, 85, 80, and 68. The achlorhydria persists when the anæmia has almost or completely disappeared, either spontaneously or as a result of treatment. Thus in three Guy's Hospital cases it was still present when the hæmoglobin percentage was 85, 82, and 80 respectively, compared with 45, 38, and 23 respectively some months or years before (Campbell and Conybeare).[7] Levine and Ladd[8] found it with the hæmoglobin 82, 104, 85, 87, 88, 85, and 90, although at one time it had been 35, 35, 28, 35, 28, 22, and 48 respectively. Still more remarkable is the case of a man who 17 years ago was in the London Hospital for typical Addison's anæmia with 700,000 red cells per cub. mm. and complete achlorhydria. The achlorhydria was still present, though for years he had been perfectly well and his red corpuscles numbered 5,200,000 per cub. mm., when he was shown at the Medical Society in November, 1922, by Maitland Jones.[9] In a case of Zadek's[10] achlorhydria was present with a hæmoglobin percentage of 108 and red corpuscles numbering 5,400,000 per cub. mm., though at his worst, four years before, the figures had been 23 and 610,000 respectively.

The achlorhydria is thus far more constant than any other symptom, not excluding anæmia. Even the anisocytosis and increase in the average size of the red corpuscles, which Price Jones[6] has shown are never absent in the active stages of the disease, sometimes disappears completely during remissions and after apparent recovery, though the achlorhydria persists. There is no constant change in the gastric secretion in any other form of anæmia. Thus fractional test-meals in my last four patients with gastric or duodenal ulcer, complicated by severe secondary anæmia due to hæmorrhage, gave curves of exactly the same form as would have been expected in the absence of hæmorrhage; the percentage of hæmoglobin in these cases was 30, 33, 48, and 49, which is quite as low as one would expect to find in an average series of cases of Addison's anæmia when first examined. In two cases recorded by Campbell and Conybeare[7] of secondary anæmia caused by rectal hæmorrhage with a hæmoglobin percentage of 44 and 42 respectively, and in two cases of chlorosis with a percentage of 25 and 48, the curves of gastric secretion were normal. Campbell and Conybeare also report a fatal case of Hodgkin's disease, in which the hæmoglobin percentage was 25 and 17 on two occasions three months and three weeks respectively before death; a test-meal given the same day as the first count and again a week after the second showed that free hydrochloric acid was present, though in small quantities. It is obvious, therefore, that anæmia does not cause achlorhydria.

The achlorhydria is not of a specific type, but whatever its origin may be, it predisposes to the development of Addison's anæmia. The history in most cases points to the achlorhydria being of primary or constitutional form, which Bennett and Ryle have shown exists in about 4 per cent. of normal young men, and which Albu and Jung found may occur in two or more members of the same family. This is undoubtedly the inherited factor in the cases of familial Addison's anæmia, which have been recorded with increasing frequency in the last few years. Mustelin,[11] for example, had under his care a woman of 69, her daughter of 44, and the latter's daughter of 25, all of whom had Addison's anæmia and achylia gastrica. Still more important are the cases in which various members of the family of a patient with Addison's anæmia are found to have achlorhydria, though apparently in perfect health. Martius having found achlorhydria in the three children of a patient with achlorhydria, who died of Addison's anæmia, his assistant, Weinberg,[12] examined the gastric contents of 22 children and two sisters of 12 patients with Addison's anæmia and achylia gastrica in Martius's clinic at Rostock. Nine of the children and one sister of seven of the 12 patients had achlorhydria. The most striking history was that of a man with Addison's anæmia, who had four children; of these a boy of 10, a boy of 6, and a girl of 4 had achlorhydria. At this early age it is obvious that the abnormality must have been constitutional and congenital and not acquired. Quite recently Schauman[13] described a family, in which a woman, her mother and sister and the latter's daughter suffered from Addison's anæmia, and another sister had achylia gastrica but no anæmia.

In one of my cases the achlorhydria was due to alcoholic gastritis, in another Guy's Hospital case it resulted from a gastro-enterostomy for ulcer, and—what proves conclusively that it is primary and not secondary—I know of at least five cases in which Addison's anæmia followed the artificial achylia produced by total gastrectomy performed for cancer. There is thus no constant pathological change, such as atrophy, in the gastric mucous membrane after death; in one case of Addison's anæmia, in which a fragment was excised during an operation for appendicitis, R. D. Passey found no atrophy and no more inflammation than in a specimen obtained under similar circumstances in a case of achlorhydria without anæmia.

SUBACUTE COMBINED DEGENERATION OF THE SPINAL CORD AND ADDISON'S (PERNICIOUS) ANÆMIA.

If patients with Addison's anæmia are carefully examined, about 80 per cent. show definite signs of spinal cord disease. The symptoms, physical signs, and pathological changes are identical with those of subacute combined degeneration of the spinal cord, in which the nervous symptoms are primary, but anæmia develops sooner or later in almost every case. There has been much discussion as to the nature of this anæmia, but I believe that if the blood is repeatedly examined with sufficient care, it will always prove to be of the so-called pernicious form. Digestive symptoms are as common when the nervous symptoms precede the anæmia as when the reverse is the case, and they are frequently the first symptoms to be noticed by the patient. J. R. Bell of Melbourne and I[14] have had the opportunity of investigating ten cases of typical subacute combined degeneration of the cord by the fractional method of gastric analysis. In all ten free hydrochloric acid was completely absent throughout the period of digestion. I know of one additional case in which achlorhydria was discovered in a patient with digestive symptoms a year before the first signs of subacute combined degeneration of the cord appeared. For purposes of control, gastric analyses were made by J. R. Bell in a series of typical cases of disseminated sclerosis and tabes dorsalis. In eight consecutive cases of disseminated sclerosis achlorhydria was never found, the curves of acidity being the same as would be likely to occur in a series of eight normal people. Of nine consecutive cases of tabes dorsalis one was found to have achlorhydria; the remainder had curves which fell within normal limits.

Gastric analysis may, therefore, give information of real help in diagnosis, the presence of free hydrochloric acid in any fraction of a test-meal being a decisive point against the diagnosis of subacute combined degeneration, whereas the discovery of achlorhydria would considerably strengthen the probability of such a diagnosis being correct. In three recent cases, which presented features very suggestive of subacute combined degeneration, a normal curve of gastric acidity was discovered. Each eventually proved to be a case of syphilitic disease of the spinal cord. These cases are analogous with two others, the only cases in Guy's Hospital in which a diagnosis of "pernicious" anæmia had been made, in spite of the fact that free hydrochloric acid was present in the stomach. At the post-mortem no evidence of hæmolysis was present, one being found to have infective endocarditis, and the other, who died of pneumonia, had microscopical changes in the spleen which were typical of Hodgkin's disease.

THE EVIDENCE OF INTESTINAL INFECTION IN ADDISON'S (PERNICIOUS) ANÆMIA AND SUBACUTE COMBINED DEGENERATION OF THE CORD.

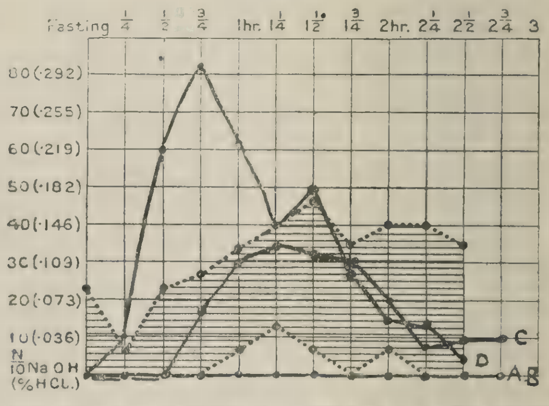
The importance of oral sepsis in Addison's anæmia has been universally acknowledged since Hunter first drew attention to the subject over 20 years ago. Streptococci are almost invariably present in the sockets of septic teeth, whether the individual is otherwise healthy or not, but so far as our observations go the *Streptococcus longus* is not often found in the contents of the duodenum removed during life with a Ryle tube, except in Addison's anæmia and in subacute combined degeneration of the cord. In four normal individuals and in 37 patients suffering from various medical conditions the duodenal contents contained the *S. longus* in only four instances. In six of the 37 cases achlorhydria was present, together with very severe oral sepsis in two and slight pyorrhœa in a third, but in spite of this no streptococci were found. In every one of the nine cases of Addison's anæmia and the four cases of subacute combined degeneration of the cord which we have investigated *S. longus* was obtained on cultivation of the duodenal contents.

In spite of the somewhat small number of cases, the contrast between the 9·8 per cent. of controls, in which streptococci were found, with 100 per cent. of Addison's anæmia and subacute combined degeneration of the cord, is so striking that the conclusion can probably be drawn that an infection of the intestine with *S. longus* is an essential factor in the production of these diseases. In any case the presence of *S. longus* in the duodenum is evidence of active infection of the intestine. In achlorhydria proteins pass into the duodenum in an unaltered form, and bacteria from the mouth and nasopharynx are likely to reach the intestine in far greater numbers than under normal conditions. If achlorhydria is associated with oral sepsis, secondary infection of the intestines is extremely likely to occur. Consequently in Addison's anæmia and in subacute combined degeneration of the cord intestinal infection is likely to be associated with the presence in the intestines of excess of undigested or incompletely digested protein. Under such conditions it is not surprising that toxins are produced by the bacterial destruction of proteins in abnormal quantities in the intestines. It is probable that one of these is specially toxic for the blood and leads to a hæmolytic form of anæmia, and that another is specially toxic for nervous tissues and leads to combined degeneration of the spinal cord. In most cases the former toxin is the dominant one, but in a small minority of cases the latter is the more important. Although one or other may appear to be present alone in the early stages, it is rare for the hæmolytic toxin and still more rare for the neurotoxin to continue to be produced without the other throughout the course of the illness.

TREATMENT OF ADDISON'S (PERNICIOUS) ANÆMIA AND SUBACUTE COMBINED DEGENERATION OF THE SPINAL CORD.

The most important part of the treatment of Addison's anæmia and subacute combined degeneration is to overcome the intestinal infection and so stop the development of the neurotoxic and hæmolytic poisons. Oral sepsis should be thoroughly dealt with, as Hunter first demonstrated in 1900. Every tooth which shows the slightest sign of infection on expert clinical examination should be condemned. An X ray photograph should always be taken of all the remaining teeth, however healthy they may appear,

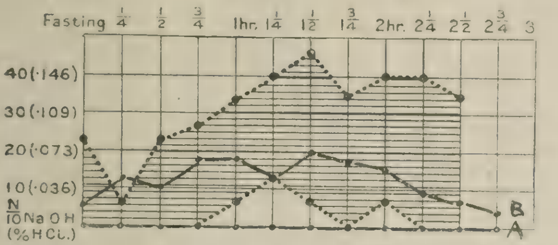
FIG. 1.



Fractional test-meals to show free HCl in a man with subacute combined degeneration of the spinal cord. A, without addition of acid—complete achlorhydria; B, with addition of ʒi. dilute HCl (B.P.) in ℥iv. water (0·3 per cent. HCl), taken with the gruel—complete achlorhydria; C, with addition of ʒiss. dilute HCl in ℥vi. of water—normal curve; D, with addition of ʒii. dilute HCl in ℥viii. water—hyperchlorhydria curve. The shaded area represents the limits for free HCl of 80 per cent. of normal people.

and the slightest sign of apical infection or periodontitis should lead to their removal. In most cases every tooth will have to be extracted. If the tonsils are infected they should be enucleated, and the nose and nasal sinuses should also be examined and, if necessary, thoroughly treated. The achlorhydria should be corrected by the administration of large doses of hydrochloric acid. In most cases we have found that a drachm and a half of dilute hydrochloric acid are required in order to compensate for the deficiency of gastric juice (Figs. 1 and 2). The acid should be added in the proportion of a drachm to 4 ounces of water in order to make a beverage, the acidity of which is about the same as that of gastric juice; lemon juice and sugar are added to make it more palatable, and it should be drunk during the course of each meal. The patient should continue to take it without intermission for the rest of his life, as even if the intestinal infection appears to be overcome the achlorhydria probably always remains. Milk which has been soured with an active lactic acid bacillus should also be given for an indefinite period. Most patients can take half a pint three times a day without difficulty.

FIG. 2.



Fractional test-meals to show free HCl in a woman with subacute combined degeneration of the spinal cord. A, without addition of HCl—complete achlorhydria; B, with addition of ʒiss. dilute HCl in ℥vi. water.

Lastly, a vaccine should be made from any streptococcus which can be isolated from the sockets of extracted teeth, from the duodenal contents withdrawn through Ryle's tube, from the fæces and from the urine. This should be given in carefully graduated doses, beginning with very little, and slowly increasing, but it is desirable that no general reaction should follow the injections. In severe cases symptomatic treatment is required for the anæmia in the form of transfusion, arsenic given by mouth or injection, and occasionally splenectomy, and for the nervous symptoms by re-education.

It has been a special pleasure to me to refer in this second lecture to the connexion between digestive disorders and a nervous disease, because of the debt I owe to the teaching of such distinguished Parisian neurologists as Raymond, Dejerine, Marie, and Babinski, from all of whom I received much kindness and learnt many valuable lessons during the same three months as those in which I attended the clinic for disorders of digestion at the Hôpital St. Antoine of that great physician, Albert Mathieu.

DEEP X RAY THERAPY.

THE TECHNIQUE OF THE ERLANGEN CLINIC.

Abstract of a Lecture delivered at the City of Dublin Skin and Cancer Hospital.[1]

BY DR. W. PILGER,
ERLANGEN, BAVARIA.

I PROPOSE to begin my lecture with a brief description of the new plant, the so-called "symmetry" apparatus, used at Erlangen for deep X ray therapy. The plant consists of an inductor apparatus with a gas-mercury interrupter, and the coil is divided into two symmetrically arranged parts. By this means it is possible to raise the secondary voltage applied to the tubes up to 200,000 volts without danger of leakage. Furthermore, by this arrangement, together with the two water resistance tubes, the electrical waves which have a detrimental effect on the average voltage are suppressed. The inverse currents are suppressed by a point-plate spark gap in a tube placed between the two parts of the inductor. The apparatus has been in constant use for the last nine years in the Erlangen Clinic without getting out of order. It fulfils all the requirements needed for deep therapy—i.e., a high voltage can be produced, giving hard X rays of constant quality and quantity, continuous over a long time. Coolidge tubes as well as gas tubes can be used; an arrangement is included for automatic regeneration in order to maintain constancy in self-hardening gas tubes.

Measurement of the Dose.

The measurement of the dose of X rays is made by means of an instrument called the iontoquantimeter. It is based on the ionising effect of the X rays in the air. It has been discovered that this effect is proportional to the intensity of X rays absorbed in the air, and the intensity is proportional to the absorption of X rays in the body. The iontoquantimeter consists of (1) an ionisation chamber, and (2) an electrometer. The ionisation chamber is of aluminium about 2 to 3 inches long, inside of which is a thin aluminium needle well insulated from the wall of the chamber. This needle is connected by means of highly insulated wire with an electrometer, which can be charged by a small friction machine. All this is neatly arranged on a movable trolley.

The iontoquantimeter works as follows: By the ionising effect of the X rays in the chamber, the air in the chamber becomes a conductor for electric current; the electrometer is discharged to earth, and the time that elapses during the discharge—measured by a fixed scale—is proportional to the quantity of X rays effectively absorbed. Thus the quantity of X rays is itself measured; the shorter the time, the greater is the intensity of the rays. The quality—i.e., the wave-length of X rays, determines the power of penetration. To measure this we must determine what has been left of the X rays at a certain depth, after they have entered the body at a particular port of entry, in relation to the intensity of X rays on the surface area. Prof. H. Wintz, of Erlangen, has introduced the idea of the percentage depth dose. The dose at a depth of 10 cm. is expressed as a percentage of the dose at the surface; for instance, percentage depth dose 20 means that if the surface dose is set at 100, the depth dose at 10 cm. is 20. To measure the quality of X rays the percentage depth dose is measured; if the condition of the absorbing material (i.e., the body), the size of field, and the focal distance are the same, the percentage depth dose is an exact measurement of the quality of X rays. The measurement of the percentage depth dose is taken by means of a water phantom or wax block; the discharge time is measured on the surface and then below it. The times are in inverse proportion to the doses. Briefly, the percentage depth dose depends on three factors: (1) the hardness or quality of rays, (2) the focal skin distance, (3) the field size. The harder the rays the greater the focal distance, and the greater the field size the greater the percentage depth dose. It is therefore possible by changing these three factors to adapt the percentage depth dose for various pathological conditions. By means of standardised tables various doses at any other depths than 10 cm. can be calculated.

---

[1] Dr. Pilger was invited by the staff of the City of Dublin Skin and Cancer Hospital to assist them in setting up the new plant at the hospital. Although holding no official position at Erlangen Clinic, Dr. Pilger has been closely in touch with the work there.—ED. L.

Dosage.

To calculate the dosage certain measurements of the patient's body are required, together with a fixed *biological skin dose*, the so-called unit skin dose or erythema dose—i.e., a dose that produces slight reddening after eight days, and a brownish colour after four weeks. It was established by Prof. Wintz that this dose could be fixed within a limit of about 15 per cent. The dose given in a known number of minutes' exposure, with a known apparatus and a tube running under known conditions, was standardised as 100, and produced a discharge of the iontoquantimeter in a known number of seconds. This discharge of the iontoquantimeter in a known number of seconds gave the unit skin dose.

Thus we secured calibration of the iontoquantimeter in relation to the biological effect, and could determine in advance the biological effect of other tubes by means of this instrument. The unit skin dose being standardised as 100, the proper dosage could be ascertained for various pathological conditions. The following is the dosage fixed for various conditions: Cancer, 90 to 110 per cent.; sarcoma, 70 to 80 per cent.; ovaries (sterilisation), 35 per cent.; and so on.

Technique.

To understand how the Erlangen technique is developed from the above deductions, let us first take the problem of sterilisation. Various gynæcological diseases, manifested chiefly at the age of 40 and after, are based on deficient function of the ovaries, which cause metabolic changes and other disturbances. Uterine myomas are correlated with the ovaries, and shrink when the function of the ovaries is eliminated. All these diseases are indications for suppression of the function of the ovaries by sterilisation. As I have already stated, the sterilisation dose was found to be 35 per cent., applied to the ovaries with the symmetric apparatus and Coolidge tube. When the focal distance used is 23 cm., and the field size 6 × 8 cm., we get about 18 per cent. at a depth of 10 cm., with 100 per cent. at the skin. The ovaries lie at a depth of about 10 cm. Two exposures of each ovary, one in front and the other behind, each lasting about half an hour, give the sterilisation dose. After from four to six weeks ovarian function ceases, and there are no more metabolic or other disturbances.

Uterine cancer can be treated in the same way. Six to seven ports of entry are required, all concentrating on the tumour, which thus gets 100–110 per cent. After six weeks the parametrium is treated in a similar way. I might here mention that treatment can be given with this apparatus in two ways: (1) concentrated or "cross-fire"; (2) distance field (to be described later). The cross-fire method is specially suitable for centrally situated cancer. But new difficulties arise with cancers of more irregular extension and eccentric situation, which make it impossible to concentrate the rays on them from every side. For instance, in cancer of the breast or skin, the only way is to give the dose in two or three exposures, which can only be done by augmenting the percentage depth dose. As before mentioned, the percentage depth dose depends upon three factors: (1) absorption (2) dispersion, and (3) amount of scattering. The loss from absorption can be reduced by using the hardest rays possible; modern apparatus gives radiation that cannot be much improved in quality by increase of voltage and filtration. Secondly, dispersion can be reduced as much as possible by augmenting focal distance, but this gain is only possible by sacrificing time. The time of exposure increases with the square of the distance; so this gain, although quite considerable, is also limited. Thirdly, the amount of scattered rays can be augmented by enlargement of the cone of irradiation—i.e., by enlarging the size of field covered by scattered rays formed when the primary rays meet the molecules of the tissue. Briefly, then, the percentage depth dose can be improved by increase both of field size and focal distance. If, for instance, the cancer lies at a depth of 1–3 cm., with a field of 6 × 8 cm. and a distance of 23 cm., a dose of 53 per cent. would be obtained at the inner border of the cancer. A distance of 20 cm. would give 65 per cent.; by enlarging the field to about 20 × 20 cm. 80–85 per cent. would obtained.

Accordingly, cancer of the breast is radiated by two distant exposures, one in front and the other behind. The distance and field size depend on the situation and size of the tumour. The irradiation doses to the tumour and the axilla may be given at the same time or separately; the supraclavicular glands must also be radiated. As the cancer dose is always calculated at the lowest limit, a second radiation is generally given in these cases. In cancer of the vulva, for instance, we have a distance field of 1 metre and give additional doses to the inguinal glands. In short, every case must be treated individually, with due regard to the above-mentioned principles.

Method of Applying Treatment.

Both the concentrated or cross-fire method and the distance field method can sometimes be employed. Their advantages are as follows. In the cross-fire method the blood recovers within about three weeks; the method is more difficult and dangerous, requiring the exercise of much skill. The distance method is comparatively simple; larger areas of the body can be radiated, more rays are absorbed, and six to eight weeks are required for the blood to recover.

General harm and nervous disorder may be caused to the body by large X ray doses, the effect being chiefly manifested in the blood circulation. A sudden fall of lymphocytes and relative leucocytosis occur; whenever possible, therefore, large cones of irradiation are avoided and concentrated doses given. The use of a compressor is recommended when the cross-fire method is adopted. Compression produces anæmia of the skin, which is thus rendered slightly less susceptible to X rays. Secondly, the movable bowels are pressed aside (in the case of abdomen), so that they do not interfere so much with the cone of radiation. For good results to be obtained the patient must be in a fit state for treatment, just as in any major operation, the condition of the blood is of paramount importance and must be ascertained.

Blood Examination.—Blood examination must be made before and after treatment, both relative and absolute counts being made. Usually we find after having given a large dose that lymphocytes are decreased, and at the same time relative leucocytosis and slight diminution of red corpuscles take place. If the patient's previous condition was good he recovers after three or four weeks if the subsequent treatment is correct.

Preparation of the Patient Before Treatment.—(1) As usual for a surgical operation; (2) nothing is to be done to the areas of radiation; (3) patient to be given a light cup of tea in the early morning and nothing else; (4) there should be no barium residue in the bowels; (5) no medicaments containing iron or other metals to be given; (6) scopolamine or morphine should be injected on the table.

After-treatment.—(1) Avoid all irritation to the radiated part of the body, from clothes, rubbing, scratching, soap, irritating ointments, &c.; (2) therefore apply for some weeks, every day, unsalted lard or unguentum leniens molle; (3) give rectal injections of pure olive oil in gynæcological cases to protect mucous membranes of rectum and colon; (4) in cancer of the bowels anastomosis before radiation is recommended, as it prevents the radiated part from being constantly irritated by the contents of the stomach; (5) never make any incisions on the radiated areas if there happens to be swelling or induration after the treatment of X rays; (6) vomiting, headache, and thirst, which often occur after treatment, pass off as in the case of surgical operations; (7) a subcutaneous injection of physiological saline is recommended after radiation—each case being treated on its merits; (8) intravenous injections of albusol (a preparation of pure proteins) are given in cases of anæmia and when the patient is of a nervous type; (9) iron, arsenic, and other general tonics are useful; (10) calcium lactate has also been found of use.

Results.

Having regard to the above principles, good results can be obtained in all kinds of malignant growths irrespective of the question whether operable cancers should be treated only by X rays or should be operated and subsequently treated by X rays. There is no doubt that the use of this new weapon marks a great advance in the fight against cancer. Sufficient time has not yet elapsed to show whether this new branch of therapy will completely replace surgery in the fight against malignant growths; but the results obtained are, up to now, at least as good as those of surgery. In this connexion we must take into consideration the fact that in compiling statistics the surgeon only includes operable cases and excludes inoperable ones, whilst X ray therapy statistics include a large amount of inoperable cases, in which X ray is the only possible treatment.

Other types of suitable cases for X ray treatment are sarcomata, lympho-sarcomata, lympho-granulomata (Hodgkin), myomata, and climacteric diseases. The results obtained in the latter are so excellent and the treatment is so agreeable and safe that there is no possibility of discussion about it. In Germany operation is no longer performed on a myoma unless there are necrotic and infectious parts in it, or unless the tumour be so large that it threatens the function of the bladder or rectum.

During the past few years Prof. Wintz has introduced into the Gynæcological Hospital in Erlangen a remarkable means of treating chronic inflammatory conditions of the adnexa. These conditions are very tedious, for the Fallopian tubes and the ovaries resist all kinds of treatment; the growths are subject to recurrence by reason of the monthly congestions that take place in the female genital organs. By suppression of the function of the ovaries for two or three years, by a suitable dose (a little smaller than the full castration dose) of X rays applied to the ovaries excellent results in these diseases have been obtained. Other diseases which can be successfully treated by X rays are tuberculous glands, and tuberculosis of the peritoneum and joints, especially small joints.

It would take too long to enumerate all the skin diseases that can be successfully treated by X rays, but in general it has been found that the use of hard penetrating rays gives better results than the use of soft rays. Excellent results have been obtained in advanced cases of actinomycosis. Other suitable cases for treatment are glands of internal secretion, either in order to suppress hyperfunction or to stimulate deficient function. The exact dosage in these cases has not yet been completely worked out. In the treatment of Basedow's disease two-thirds of unit skin dose to the thyroids and the thymus is the best.

Summary of Diseases Treated by X Rays.

(1) All malignant growths of cancerous type; (2) sarcomata, lympho-sarcomata, lympho-granulomata; (3) myomata and diseases of the adnexa; (4) T.B. glands, peritoneum, and joints, especially small joints; (5) actinomycosis; and (6) disordered functions of glands of internal secretion.

The number of treatments ranges from one to four.

I have only given a short review of the various kinds of diseases in which X ray therapy has come to play a dominant part in consequence of the exactitude of application which is now possible. The period of inexact treatment—that is to say, the time when X rays of unknown quantity and quality were used—is now over, and a basis for further progress has been obtained.

SOME RESULTS OF
DEEP X RAY THERAPY.

By REGINALD MORTON, M.D., F.R.C.S. EDIN.,

AND

HARRIE B. LEE, D.S.O., *M.C.*, M.B., B.S. MELB.

THE time has not yet come for us to analyse the results of deep X ray therapy in malignant disease, although we now have over 600 cases to refer to, for the following reasons: (1) Over 95 per cent. of the cases treated have been sent up by surgeons or others with the comment "inoperable" or "inoperable recurrence after operation." Such being the case, the percentage of good results is necessarily small, and any figures based on such results would be misleading. (2) In a large majority of cases treated, general dissemination had already begun, and although the primary focus has disappeared after treatment, death has quickly ensued from involvement of the liver, mediastinum, &c. Here, again, figures would give quite a wrong impression of the results. (3) In regard to the comparatively few early cases treated, the longest interval since signs of the disease have disappeared is only 18 months, a period quite inadequate within which to say whether they are to be classed as cures or not.

Although averse from publishing figures we are of the opinion that the medical profession would welcome some information on the results to be expected from the treatment. The impression that in deep X ray therapy we have a certain panacea for all the ravages of "cancer" is, unfortunately, at the present time very far from being the truth, and we feel that with the following information at their disposal medical men will be in the position to put the pros and cons of the treatment before patients seeking advice on the subject. With this object in view we have taken one case from each group (arranged anatomically), and now publish the notes entered on the case history cards. Words in inverted commas are taken from written reports, either of the patient or his doctor. Other considerations being equal, we have taken cases on the following points: (1) Apparent hopelessness from a surgical point of view, and (2) the degree of benefit derived from the treatment.

We candidly admit we have picked out successful cases to show what can be done when the conditions are favourable. What exactly constitutes "favourable conditions" we do not at present know; cases that one would expect to do well have not done so; and others to whom treatment has only been given as a placebo at the urgent request of the relatives have done surprisingly well. This would seem to indicate that our technique is still faulty, and allows us to hope that as our experience widens the technique will improve, and the results will become correspondingly better. In the following notes we wish to emphasise the fact that in every case the diagnosis is that of the surgeon who referred the case to us, made in many cases on the microscopic examination of the growth after removal, in others only on the general clinical findings in the case. In this latter class we quite realise that there may be an element of doubt as to the accuracy of the diagnosis; but we do not think that experienced surgeons make many errors in cases where the signs are so marked as they have been in the great majority of patients treated. The exceptions are the few early cases of tumour of the breast with no glandular involvement, and in these a query mark has always been put after the diagnosis.

Technique.

As this is not a technical article, a few words will suffice as to apparatus and technique. We use the "symmetry apparatus" of Schaerer, activating Muller's boiling water gas tubes. Recent visits to America and to the continent have tended to confirm the opinion that at the present time apparatus conforming in general principles to the above gives results at least equal to those obtained by any other method. Our technique has in the main been based on that of Prof. H. Wintz, of Erlangen. That is to say that for attacking deep-seated growths multiple small ports of entry are used. Quite recently we have introduced some important modifications with beneficial results, but these will be discussed later in a technical article. One important result should, however, be mentioned here. Formerly patients suffered very considerably from nausea and vomiting towards the end of the treatment, which lasted on an average about five and a half hours. The improvements mentioned above have resulted in the shortening of the average time of exposure to four hours, and nowadays the occurrence of nausea and vomiting during treatment is quite exceptional. This is rather important, for it means that we can now treat cases which previously we had to refuse, as their general condition was too low to run the risk attached to a severe attack of vomiting with its added strain on a weakened heart. With the object of obviating these unpleasant effects, some radiologists have adopted the expedient of spreading the treatment over five or six days, giving an hour at each sitting; but we are of the opinion that this lowers the efficiency of the dose very considerably. We hope to show that no case is too far gone to be beyond the chance of a considerable prolongation of life, or at least that the end will be made much less distressing both to the patients and the relatives. In this connexion we would also emphasise the great importance of having a large, light, airy room in which to give treatment, otherwise the patient is exposed to an atmosphere very considerably vitiated by the working of the apparatus, and this must result in the lowering of the general condition.

In many cases it has been found necessary to repeat the treatment. This can only be undertaken after an interval of at least six weeks, as it takes that time for the skin to recover from the previous irradiation. During the interval everything possible should be done to build up the patient's general condition. It must be remembered that exposure to the rays causes a certain amount of destruction to the red blood corpuscles. Our investigations tend to show that this destruction is not as great as has been reported; nevertheless it is important. We make a practice of doing a blood count before treatment. If the red count is below 4,000,000 the patient is given a preliminary course of intramuscular injections of iron and arsenic, or in very severe cases he is sent for a course of ultra-violet radiation. Then in all cases iron and arsenic are administered after treatment for a period of five weeks, with the result that a second dose can be safely given after the necessary six weeks' interval. In connexion with the repetition of the dose we must refer to an article just published by Prof. Wintz, which deals with certain changes in the normal tissue which may result from over-dosage with X rays. In the majority of cases these are due to faulty technique and can be avoided, but in others the trouble appears in spite of all precautions. The commonest of these is that the skin becomes more susceptible to trauma, and slight injuries produce effects out of all proportion to their severity. Healing takes place rapidly, however, and the condition does not in the slightest degree resemble an X ray burn. In all cases of disease of the bladder, prostate, and rectum a transient irritable condition of the mucous membrane is produced, which as a rule passes off rapidly, but in a small proportion of cases it persists, and results in the formation of ulcers—which, however, respond readily to treatment. The most serious sequela to over-dosage, however, is that in some breast cases which have been repeatedly irradiated a collapse of the underlying lung takes place; this is of serious import if pneumonia and bronchitis supervene, but spontaneous recovery occurs in about nine months if no other complications appear. In our experience of over 600 cases we have noticed only one case of severe injury to the skin and none of serious damage to the lung. The skin case has now quite recovered.

To sum up, we think that the treatment has now fairly established itself as a method of dealing with cases when nothing else can be done; the results in all cases make the treatment worth while, and in a few cases border on the miraculous. Whether in the early cases surgery should be discarded in favour of X rays it is as yet too early to say, but it may be stated that in all early cases treated symptoms and signs have disappeared and that so far there has been no recurrence. When surgery is resorted to we would strongly urge the employment of X ray deep therapy, either before or after operation (preferably the former), as a prophylactic measure against recurrence.

Case Reports.

Where it is possible in the following notes extracts have been taken verbatim from the reports of the surgeon interested both before and after treatment, and we hope that their publication will remove any suspicion of unconscious bias on our part. The generalisations we have appended to each class of case represent conclusions arrived at after a fairly wide experience, and any error will be found to be on the conservative side.

CASE S. 20. *Sarcoma of Naso-pharynx.*—Male aged 58. This case was referred to us by Mr. H. Tilley in October, 1921, with "a growth almost certainly sarcoma of the left ethmoidal region, spreading into the naso-pharynx, has had watering of eyes and tinnitus for last four months. Left nostril nearly blocked: no special pain, but some discomfort, and does not sleep well. Left-sided deafness." Treated Oct. 25th, 1921. On Nov. 15th the patient reported having had a very severe reaction for the first few days after treatment, followed by marked improvement. Deafness and tinnitus completely gone. Nasal breathing quite free for a time, but now becoming blocked again. Jan. 11th, 1922, Mr. Tilley reported that the growth had entirely disappeared, but that enlarged glands were palpable on the right side. This was treated and the area of the growth given a second irradiation. On Feb. 23rd the glands had entirely disappeared. In September, 1922, Mr. Tilley reported that on his last examination of the case he could find no trace of disease either in the nasal cavity or the glands.

CASE H. 9. *Lympho-sarcoma of Right Tonsil.*—Female aged 55. This case was sent by Mr. Tilley with the diagnosis of lympho-sarcoma of the right tonsil and enlarged submaxillary gland on left side. Treatment on May 22nd, 1922. On June 7th patient was seen; marvellous improvement found, growth reduced to a fraction of its former size. On August 10th Mr. Tilley reported: "I saw the patient some time ago, and she appeared to be quite well, and I have since heard from her doctor that the excellent result is still maintained." On Nov. 9th, 1922, no sign or symptom of disease was visible.

These are exceptionally good results for nose and throat cases, probably because the growth was in each instance sarcoma, as, speaking generally, we have found the various forms of sarcomata much more amenable to treatment as regards local condition than the carcinomata. Nose and throat cases are, as a rule, complicated by superadded sepsis, which in our experience always militates against a good result.

CASE S. 2. *Early Carcinoma of the Breast.* (Diagnosis queried.)—Female aged 70. In January, 1922, noticed small lump in right breast, just below nipple. On examination a tumour the size of bantam's egg, rather soft with hard centre, could be felt. Skin slightly depressed at one point. Fullness under the clavicle, but axillary and supra-clavicular areas apparently clear. Treatment on Jan. 22nd, 1922. On March 1st hard centre had disappeared, and lump was all soft and pliable. Fullness below clavicle had disappeared, and general health and appearance were much improved. On April 20th lump had disappeared; a second treatment given as a prophylactic measure. On August 17th, 1922, Dr. C. B. Voisey reported: "Patient is still getting about, but I have not examined her for some time."

CASE S. 28. *Early Carcinoma of the Breast.* (Diagnosis queried.)—Female aged 47 (from Dr. R. Wilson). For 12 months had noticed lump in left breast gradually getting larger. On examination was found to have a lump about 5 by 7 cm. in left breast, just under nipple, freely movable. Treatment on June 7th, 1921. On Nov. 18th lump about half former size, feels harder, fibrous. Given a second treatment. On Jan. 17th, 1922, lump practically gone. In August Dr. Wilson reported patient in a good state of health.

In all early breast cases there must be considerable doubt as to the diagnosis, which could only be settled by microscopic examination; this is not possible, since such patients are usually sent to us because they have declined surgical methods. We have been successful in reducing the tumour in every case, and so far no recurrence has taken place.

CASE E. 3. *Inoperable Carcinoma of the Breast.*—Female aged 40. This case was sent by Sir Alfred Fripp in January, 1922, with inoperable carcinoma of the right breast. A large tumour of the upper inner quadrant, the overlying skin discoloured and adherent to tumour, which was fixed to chest wall. Axillary glands enlarged and palpable. Prognosis unfavourable. Treatment on Jan. 26th, 1922. On March 25th Sir Alfred Fripp reported: "Marvellous improvement. The malignant characters have all gone. The texture of the skin is normal, and the discolouration has disappeared. The growth is much reduced in size and is more freely moveable. The axilla is quite clear." Patient was given a second treatment, and on May 24th a third treatment, as a prophylactic measure; the condition remained excellent. On July 28th a small tumour with retracted skin had appeared in left breast; this was given local treatment. On Sept. 19th patient was seen, with Sir Alfred Fripp. Patient complained of great dyspnœa; on examination nothing pathological could be detected in the chest, but free fluid was found in the abdomen, the diagnosis of secondaries in the liver was made, and a bad prognosis was given. On Oct. 17th patient died.

This case was very disappointing, as complete success had been achieved as regards the local condition. The patient had deliberately concealed her condition from her husband until operative measures were out of the question, and general dissemination had probably taken place before treatment was started. Unfortunately this has been the condition in nearly all the late breast cases we have treated, so that the final result is bad, although the local results are surprisingly good.

CASE D. 9. *Recurrent Carcinoma after Amputation of Breast.*—Female aged 49. In 1915 left breast was amputated for carcinoma; in April, 1921, patient noticed a small lump appearing just below left sterno-clavicular articulation. By August this had grown to a smooth raised tumour 1½ inches in diameter firmly adhering to the underlying structures. No cervical or axillary glands palpable. Treatment on August 4th. The lump disappeared almost immediately after treatment, but in November showed signs of enlarging, and patient then had a second treatment. Again the lump almost disappeared. In January, 1922, patient had third treatment. When last a report was received, in August, she was apparently quite cured, nothing even suspicious remaining.

CASE R. 1. *Recurrent Carcinoma after Amputation of Breast.*—Female aged 48. Left breast amputated for scirrhous carcinoma in 1916. On three subsequent occasions recurrent nodules removed. Now had two small nodules in the operation scar and a small gland at the root of the neck. Had had left-sided pleurisy at various times, and possibly the pleura was involved. Slight cachexia was apparent. Treatment on Dec. 13th, 1921. On August 20th, 1922, Dr. J. A. Gordon reported: "No recurrence of symptoms, enjoying fair health."

As a general rule the local result in post-operative recurrences in breast cases has been good, the tumour completely disappearing. But the same cannot be said for the general result, as the great majority have subsequently died from either liver or mediastinal involvement. We think life has, as a rule, been prolonged, and ulcerating open sores, distressful both to the patient and to the relatives, are practically excluded.

CASE N. 1. *Sarcoma of Lung.*—Male, aged 48, first seen with Dr. A. Bevan on Feb. 24th, 1922. He was very anæmic and weak with great dyspnœa, and had to be carried in on a stretcher. Dr. Bevan reported that a piece of rib had been removed and a large growth observed involving the upper lobe of the right lung and extending down over the middle lobe. A piece of the growth was removed and examined microscopically; the pathologist reported it to be sarcoma of the lung. In the radiograph the shadow of the tumour took up two-thirds of the right pleural cavity. Treatment was given with great difficulty owing to dyspnœa. On April 27th Dr. Bevan reported that the patient was very much better in every way, the dyspnœa being much improved. On May 16th the patient came for a second treatment. Marvellous improvement in the meantime, good colour, got about and enjoyed life. On August 12th radiograph showed that the tumour had now shrunk to the size of a walnut. Patient felt perfectly well. Given a third treatment. On Oct. 20th Dr. Bevan reported that the patient was still enjoying perfect health.

This case is quoted because: (1) it was apparently quite hopeless, and treatment was only given to pacify the patient's friends; (2) the diagnosis was confirmed microscopically; and (3) the radiographs form a permanent record of the efficacy of the treatment.

CASE W. 18. *Carcinoma of the Stomach.*—Male (medical man) aged 60. During the early months of 1922 had symptoms of severe gastric trouble, constant vomiting, and a progressive loss of weight. Radiographs taken by Dr. Stanley Melville showed very extensive involvement of the pylorus and pre-pyloric portions of the stomach. A mass was palpable in the epigastrium. Sir Hugh Rigby considered the case inoperable. Our own experience of gastric cases is very limited, and we advised this patient to go to Prof. Wintz at Erlangen. He did so, and was treated there on June 21st, 1922. On July 2nd Dr. Arthur Ricketts reported that he could feel no mass in the epigastrium, and that apart from the recurrent griping pains patient was feeling fairly free from symptoms. Early in August patient had a relapse with severe vomiting, and became very anæmic. Treatment here on August 8th. Very severe reaction after treatment, and a fatal issue seemed imminent. After 10 days, however, he started to improve, vomiting ceased, and he was able to go to the seaside. He has gone ahead ever since, eats practically everything with very little discomfort, has a much better colour, and on Oct. 14th was able to resume practice.

We prefer to let this case pass without further comment. Time alone will show what permanent benefit has been derived from treatment; the immediate result has been dramatic.

CASE T. 8. *Carcinoma of the Pancreas.*—Male aged 72. In February patient was operated on for gastric trouble. Found to be suffering from inoperable carcinoma of the pancreas. Brought here first in March, 1921, by Dr. Schrumpf from Paris, the tumour could just be felt in the area of the pancreas. Treatment in March, 1921. The patient then improved, gained weight, went about and enjoyed life. In August, 1922, when last heard of, he was still keeping well, and no signs or symptoms of disease were manifest.

Four other cases of pancreatic disease have been treated but too recently for any just estimate of the results to be made.

CASE S. 17. *Carcinoma of the Rectum.*—Female, aged 38, has had symptoms of growth in rectum since 1921. Sent to us on April 5th, 1922, by Dr. Andrew Fullerton, of Belfast, complaining of great tenesmus and pain with bowel action. Passing considerable quantities of blood and mucus. Per rectum a large growth to be felt, about 4 inches up the rectum, causing almost complete blockage. Diagnosis carcinoma of the rectum. Given routine treatment usual in these cases. On August 8th Dr. Fullerton wrote: "I can't find any tumour of bowel now—only a narrowing." Sept. 27th, 1922, patient came for a second treatment as a prophylactic measure. Feels and looks well, and has no sign or symptom of active disease.

Speaking generally, the rectal cases have done very well indeed. The local symptoms in all cases have abated, obstruction has been less, hæmorrhage has ceased, and the palpable tumour has become distinctly smaller. With this local improvement has followed naturally a dramatic change in the general condition. The colour improves, weight is increased, and the patient is able to enjoy life. What the ultimate result is going to be it is too early to say, but we maintain that no case should be submitted to a colostomy until deep therapy has been given a trial, and we feel sure that the necessity for operation would vanish.

CASE S. 14. *Carcinoma of Prostate.*—Male aged 66. Sent by Sir J. Thomson Walker with diagnosis of inoperable malignant prostate. General condition bad, confined to bed, having narcotics to relieve pain, which was intense. Growth more noticeable on left side. Treatment on Feb. 13th, 1922. On May 24th was examined at nursing home. No enlargement of middle lobe palpable, left lobe about half former size. No trouble with micturition, but rectum is irritable. General condition is much improved, but patient still too weak to get about. On June 13th a second treatment given, with precautions to avoid rectal irritation as far as possible. On August 20th Sir J. Thomson Walker reported: "Growth appears to be smaller, improved in general condition, and regained good colour. No further loss of weight. Able to get about better, and has very much less pain."

The prostatic cases, whether malignant or simple hypertrophy, have been very successful indeed, unless complicated by a bad cystitis or pyonephrosis. In all cases the tumour has become markedly diminished in size. Hæmorrhage has ceased, and micturition has become much easier. Dissemination in these cases (and the same applies to rectal cases) is always slow, and with the abatement of local symptoms a very considerable prolongation of comfortable existence can be expected.

CASE Y. 1. *Carcinoma of the Urethra.*—Female aged 67. Sent by Dr. J. E. Frere with diagnosis of slowly progressive carcinoma of the urethra involving the wall of the vagina. Has been treated by radium, which held it up for a time, but it is now slowly progressing. Treatment on March 24th, 1921. On April 14th patient was more comfortable than for some months past; blood-stained discharge has ceased. On July 17th Dr. Gordon Luker and Dr. Frere examined her and reported: "Very definite improvement in local condition, she seems very well and has no untoward symptoms." On Sept. 3rd, 1922, Dr. Frere reported patient doing very well: she was last examined by Dr. Luker in February, 1922.

The general remarks on prostatic cases apply to bladder cases in general.

CASE H. 5. *Inoperable Carcinoma of the Cervix.*—Female aged 50. Sent to us in November, 1921, by Mr. Aslett Baldwin, with a history of an offensive sanious discharge from the vagina since February, 1921, increasing latterly with pain in the back and right groin. Diagnosed: "Inoperable breaking-down carcinoma of cervix." Treatment on Nov. 7th, 1921. On Jan. 4th, 1922, per vaginam the cervix was found to be contracted and firm; discharge had ceased, and pain had almost entirely gone. General health was much improved. Given second treatment, mainly to left side. On March 7th, 1922, no ulceration or friability of cervix could be detected. On May 18th patient had some hæmorrhage and recurrence of pain. Per vaginam conditions remained as before; treated. On July 27th nothing friable in vagina. Uterus moved freely. Patient looked very well generally. Still had some discharge per vaginam; treated.

This is fairly typical history in this class of case. Improvement is always slow but progressive, and in no case that we have treated has general dissemination taken place. In our opinion the danger of the treatment causing vesico-vaginal or recto-vaginal fistulæ has been exaggerated. We have had only one such case, and even here we think that the disease rather than the treatment was responsible. We have had no experience in treating "operable" cases, but judging by the results obtained in the severe cases, and the published figures of the Erlangen Clinic, there seems to be every hope of treating them successfully.

Messrs. Methuen and Co. are bringing out an eighth edition of Miss M. N. Oxford's "Handbook of Nursing."

ROYAL MICROSCOPICAL SOCIETY.—The annual meeting will be held in the Lecture Hall at 20, Hanover-square, London, W 1, on Jan. 17th, at 7.30 for 8 P.M., when Prof. Frederic J. Cheshire will deliver the presidential address on the Early History of the Polarising Microscope.—A new combined section of the Society, dealing with the practical use of the microscope in connexion with industrial research, has been formed. The inaugural meeting will be held at 20, Hanover-square, W. 1, on Wednesday, Jan. 24th, at 7 P.M., Prof. Cheshire presiding.

THE
ATAVISTIC-DEGENERATIVE DIATHESIS OF TUBERCULOSIS.

BY W. C. RIVERS, M.R.C.S. ENG., D.P.H.,
TUBERCULOSIS OFFICER, BARNSLEY DISTRICT,
WEST RIDING, YORKS.

A GOOD way of investigating scientifically intrinsic predisposition, amongst the civilised races, to tubercle, is one that has proved fruitful in other fields of inquiry. It consists in the accumulation of *individual characters* which can be shown (*a*) to be commoner in the tuberculous than in the non-tuberculous, and (*b*) not to be themselves caused by that disease. Of course, prominence will be given to such of these individual characters as, from our knowledge of tuberculosis, we can recognise as manifestly increasing their possessors' liability to it. From such an accumulation of facts, some generalisation, and many useful inferences, should be possible.

Now already, in the literature, there have been recorded certain individual characters which all fulfil postulate (*a*), and of which some also fulfil—and none have been shown to fail to fulfil—postulate (*b*). These observations are epitomised here for several reasons. Firstly, their general neglect by recent authors—a phenomenon due to the fact that many of these writers are general physicians, bacteriologists, or sanitarians, who have necessarily inadequate time for the huge special subject of tuberculosis. Secondly, current medical literature is a mighty, but fruitful, maze into which it is a beneficial act to introduce more plan. And lastly, with the facts set out, however briefly, before us, there do appear grounds, of a magnitude previously unsuspected, for the generalisation now beginning to be made, the generalisation adumbrated in the title of these remarks. To begin with the nervous system.

Nervous System.

The especial liability to tubercle of the insane is a truism. That such liability is not merely a matter of environment, or of depressed health produced by mental affection, is proved by such details as the persistence of a high incidence of tuberculosis in modern healthy asylums, where the life is largely out-door; as the especial vulnerability of idiots and the subjects of dementia præcox and of primary dementia; as the tuberculosis of lunatics, like the tuberculosis of savages (and, to a less extent, of infants) being acute, and attacking mainly, to begin with, the lymphatic system and the lungs. Further, the excess in question is much too big to be reasonably attributable to extrinsic causes. In 1901 in England and Wales, in a population of 32½ millions, there were about 60,000 deaths from tuberculosis, a death-rate under 0·2 per cent. The same figure for borough and county asylums was 15·8. No amount of correction for age and sex distribution could leave that disparity other than huge. Moreover, the insane are prone also to pulmonary gangrene, whilst asylum attendants show no special proclivity either to that disease or to tubercle. Lastly, Sir Frederick Mott, from autopsy investigation, has pronounced against tuberculosis being acquired in the asylum.

Circulation.

It is again a commonplace that congenital cardiac patients, at any rate those with the commonest variety of lesion—pulmonary stenosis plus defect of the ventricular septum (trilocular heart)—very often die of phthisis. There is then the old observation that the heart and arteries of consumptives are exceptionally small. That such smallness is not wholly due to wasting from ill-nutrition and under-functioning, but starts from an autochthonous constitutional anomaly, follows for these reasons: (1) Laennec,[1] though thinking the exiguity of the blood-vessels of consumptives due to long-standing diminution of the blood in them, doubted that the heart itself was atrophied, because of its bright-red colour. (2) Of those[2] whose autopsy work bears on the point, there is a slight majority (6 against 4) in favour of the autochthonous theory; and the six include the great names of Virchow and Rokitansky, as against only Stokes on the other side. (3) The much superior evidence from orthodiagraphic radiological examination, applicable in early disease, before wasting and debility have had time to take effect upon the circulatory apparatus, speaks clearly for a constitutional peculiarity. The small median-placed heart hanging from the arch of the aorta like a drop of liquid (*Tropfenherz*) is an appearance so much commoner in consumptives than in the non-tuberculous as to help in diagnosis. Moreover, as with many predispositional stigmata, the occasional occurrence of small heart and arteries in the non-tuberculous is further evidence that this hypoplasia is not of tuberculo-toxic origin. Brugsch,[3] from rontgenological observations on healthy soldiers, found in men of equal size individual differences in arterial capacity of as much as 100 per cent. Guarini[4] is another recent author who similarly concludes that the small median heart is originally hypoplastic, correlated with hypo-evolution of other organs, pointing to a weak constitution, and to be found in those merely predisposed to tubercle. Amongst subjects actually tuberculous it occurred in 68 per cent. According to Kraus,[5] the *Tropfenherz* may be observed in weakly children, as early as 7 or 8 years old. Stiller,[6] who has described the asthenic type of constitution, considers small heart but a part of it, and thus a predisposing factor to pulmonary tubercle. All this verifies the impressive dead-house work of Beneke (mentioned in Osler's well-known text-book), which bore out the observations of Rokitansky and of Virchow. All this harmonises, too, with familiar clinical observations—like v. Strümpell's, that a quick weak pulse will sometimes persist after phthisis has become quiescent (having, indeed, preceded the disease), especially in tall, narrow-chested subjects, in whom *Tropfenherz* is probably specially frequent; or like Grancher's, that phthisical predisposition consisted in a long-continued "amoindrissement des actes fondamentaux de la vie." The low blood pressure of consumptives may be another associated phenomenon; for Naucler[7] found cachexia in cancer unaccompanied by any great fall in blood pressure, whereas, on the contrary, cachexia in phthisis showed very low readings, the hearts of lightest weights, moreover, being found in those consumptives whose blood pressure had been lowest. Lastly, Virchow's finding of the like exiguous circulatory mechanism in chlorotics helps to explain the frequency of chlorosis in the history given by female consumptives.

Skin and Appendages.

To begin again with a text-book commonplace, hypertrichosis of the back is mentioned as a characteristic of tuberculous children. In children with bone and joint tubercle I[8] found it more than four times as often as in a comparable control; moreover, the evidence was against its being tuberculo-toxic. Shrubsall,[9] investigating anthropometrically hospital out-patients, compared the pigmentary findings in 15,000 of them with those given for the lower classes by the well-known authority Beddoes, concluding that pulmonary tubercle favoured brunettes, and that in bone or glandular disease fair traits predominated; these results were not due to any special darkness of hospital patients as a class. In Sweden Lundborg[10] found brown eyes in 9 per cent. of male and in 12·5 per cent. of female consumptives, as against 6·2 per cent. and 3·9 per cent. in male and female students respectively, and 4·5 per cent. in military recruits. This special frequency of darkness characterised also, if to a less extent, criminals and deaf-mutes. To test Shrubsall's further result, as to a difference in the complexion of consumptives and of surgical tuberculous patients, I noted the pigmentary data in Lundborg's second-cited work. Complexion not being always noted, I obtained particulars of 444 dark-complexioned persons, and 948 fair. In these the percentage frequencies of tubercle were :—

	Dark.	Fair.
Pulmonary tubercle	4·7 ..	0·6
Non-pulmonary tubercle ..	4·4 ..	1·4

This is some slight corroboration. It shows great deficiency, in a fair race, of fair people among consumptives, and considerable deficiency amongst surgical tuberculous patients. Red hair I[8] observed in 7 per cent. of 353 cases of juvenile bone and joint tubercle, but only in 3·4 per cent. of a comparable control. Lundborg ("Hereditas," p. 175) notes the same trait twice to thrice as frequently in adolescent and adult tuberculous patients (variety of disease not stated) as in normal students and in soldiers; criminals showed even greater excess. Queyrat[11] recorded tuberculosis in 52 out of 56 subjects showing "partial erythrism"—i.e., dark head hair coinciding with red pubic hair. The last observation is recalled by Prof. Schmidt's[12] mention of a "Haardisharmonie" (dark brown head hair along with a fox-red moustache, the red tint of which may not show at first) as strongly indicative of predisposition to tubercle, especially tuberculous peritonitis; and the two preceding ones by White's,[13] that red haired persons were said to be peculiarly subject to scrofula, and by Landouzy's[14] opinion that four-fifths of the serious illness amongst patients with a fine white skin and red hair was tuberculosis.

Ichthyosis I[15] [8] found seven times as often in consumptives, and nearly thrice as often in bone tubercle, as in comparable controls. Searching the literature I found corroboration from Gaskoin,[17] Tommasolli,[16] and du Mesnil.[18] Unbiased study goes to show that the ichthyosis precedes the tubercle. The same will surely be granted of pigmentary characters like brown eyes and red hair.

Defects, Abnormalities, Malformation.

Osler wrote that—

> ". . . Certain morbid conditions of the abdominal organs predispose to the development of the disease [tuberculous peritonitis] . . . the frequency with which the condition is met with in operations upon ovarian tumours has been commented upon by gynæcologists . . . a very interesting feature is the occurrence of tuberculosis in hernial sacs . . . in a majority of instances it has been discovered accidentally during the operation for radical cure or for strangulation."[19]

The particular case of *cardiac* malformation has been adduced above, whilst as regards the *respiratory tract* the association of phthisis with non-tuberculous defect of its upper (naso-pharyngeal) part will be found fully discussed in a source[15] already cited. Both obstructive and atrophic abnormalities are there shown to be much commoner in consumptives, quite independently of their disease, than in normals. *Polymastia* was found by Iwai[20] to be roughly twice as frequent in tuberculous and suspected tuberculous patients as in non-tuberculous ones, a finding confirmed by Otani, both inquiries being probably suggested by the similar conclusion of a European worker in Japan. Other abnormalities may be found mentioned in a comparison, both by external examination and by autopsy, made by Polanski.[21] Inter alia this revealed, amongst the tuberculous, a five-fold preponderance of abnormally shaped hard palate, and of pelvic projection of the fourth lumbar vertebra (making an accessory promontory); fourfold excess of absence of beard in men, of floating tenth rib, and of abnormally shaped forehead; a threefold, or nearly threefold, of misformed nose, of double hair whorl, of transposed pubic hair area (i.e., triangular instead of diamond-shaped in men, diamond-shaped instead of triangular in women), of aural anomalies, of bifurcation of the spinous processes of the lumbar and lower dorsal vertebræ, of bifurcated extremity of the sixth or seventh rib, of fenestrated xiphoid appendage, of hypoplasia of the heart, aorta, and vessels, and of abnormally shaped spleen. Also the tuberculous subjects were distinguished by a longer reach (arms laterally outstretched) in proportion to their height. The investigation was suggested by a previous one—noticed by Virchow—of Zielinski,[22] who autopsied 854 consumptives, but without control observations, and recorded the above-mentioned with other abnormalities. This is all the anticipation Polanski seems aware of, but his results are now amply corroborated. Thus the observations on abnormal shape of palate and nose recall at least four independent ones (Jarvis, Talbot, Zickgraf, and myself) to the same effect. "Costa decima fluctuans" is, according to Stiller,[6] a stigma of the asthenic type of constitution, and it was associated with thin bones, flat narrow thorax, broad intercostal spaces, puny musculature and pale skin, whether tuberculosis was also present or not (l.c., p. 169). It was also associated with enteroptosis, which reminds us of Arbuthnot Lane's association of that last condition with tubercle. In this connexion a recent paper by Davies-Colley[23] is noteworthy. He describes abnormal mobility of the lower ribs as an ailment unmentioned in the text-books; in two cases given the tenth rib was at fault, and one of these was complicated by prolapse of the cæcum and ascending colon. Again, as regards pubic hair distribution, and also beardlessness, Kretschmer[24] found frequently associated with the asthenic type of build common in dementia præcox, male subjects characterised by feminine conformation of pubic hair. In dementia præcox generally, too, the beard was scanty. This asthenic type of build is almost identical with that of "habitus phthisicus." The mention of aural anomalies is in harmony with the observation of Rossolimo[25] that absence of ear lobule is often met with in the tuberculous; while Holeman,[26] from experience of American naval seamen invalided for tuberculosis, recorded, in a paper noticed abroad, the frequency amongst them of degenerative stigmata, especially deformities of the external pinna. Lastly, hypoplasia of the circulatory system we have already had mention of by many others.

Two ocular anomalies remain. Blue sclerotics have been often described as characterising adult patients with bone and joint tubercle; it is never connected with this, though, that blue sclerotics are also found with fragilitas ossium. Possibly, then, this peculiarity of the eyes signifies bony defect. Finally, that squint is in excess in adult or juvenile phthisis, but not in bone tubercle, I have recorded in sources already given, and in The Lancet, 1921, i., 319, where I adduced the confirmation to be obtained from Luzzatto. My observation as to the association of left-handedness with squint, an ophthalmologist[27] has been good enough to confirm lately from independent work.

Recapitulation.

There are many other characters—of general development, of the alimentary system, of thoracic conformation—which have been left out because at present they do not satisfy both requirements laid down at the outset of these remarks. We may, however, use them to point the reflection that with no other disease has there been half the discussion about diathesis that there has with tuberculosis; so that to all this smoke there must be some fire. Another a priori argument is that since debilitation by disease or bad hygiene—phænotypic factors, to use the latest terminology—admittedly predisposes to tubercle, then native constitutional weakness or defect—genotypic agencies—should do the same.

But even the "short list" of stigmata above enumerated is imposing. Will anyone ascribe them all to tuberculo-toxæmia? If so, if tuberculous toxin can render a child an idiot, a youth a dement; malform the fœtal heart and stunt the arteries; grow hairs on the back, stop them growing on the chin, and on the head turn them sometimes black, sometimes red; turn the eyes brown, too, and make them squint; reveal itself as a common cause of ichthyosis; now pinch and now widen the nose; and, growing violent, loosen the lower ribs and split the vertebral spines—granted all this, the old myth of Proteus is outdone by the new myth of tuberculo-toxæmia. Yet there has been repeated at Brussels in 1922 what was said there in 1910, that the so-called stigmata of tuberculous predisposition are nothing but the signs of an already present infection.

Hyper-Variability, Atavism, Degeneration.

Now, on a better hypothesis of causation, nearly all these curious characteristics come into line; and what then confronts us is not gross absurdity but an advance in knowledge. Beginning again with *insanity*, we find it the condition par excellence in which stigmata of degeneration are found; in no varieties of it so frequently as in idiocy and dementia præcox, the subjects of which are also especially prone to tubercle. Rehm[28] found stigmata of degeneracy much more frequently in epileptics and the subjects of dementia præcox than in manic-depressive lunatics; Voisin[29] spoke of them as very numerous and excessively diverse in idiots. As for *trilocular heart* or an approach thereto, that is immediately reminiscent of the normally incomplete ventricular septum in dipnoi and in the lower reptilia.[30] *Hypertrichosis of the back and limbs* is mentioned by Darwin[31] as occurring in delicate children, not as long sparse hairs over an inflamed joint, of which also he was aware, but as persistent fœtal lanugo, the rudiment of the uniform hairy coat of animals, an atavistic "theroid" trait he mentions as frequent in idiots. There is evidence that in northern races *darkness of complexion* is an atavistic-degenerative trait. Lundborg (l.c.) found dark eyes especially in the Swedish lower orders, who he states were of more mixed race than their social superiors. Now we must remember here, as often henceforth, that crossing of race is a fertile source of reversion or atavism (cf. Darwin's classical reconstruction of the primitive jungle fowl by interbreeding two modern varieties of poultry), also, probably, to take a wider view, of hyper-variability. Lundborg found this eye-darkness to characterise also Swedish criminals and deaf-mutes. If we remember Lombroso's and Nordau's theory of the degenerative character of genius, it is significant that Havelock Ellis[32] gives dark complexion as highly characteristic of noted British actors and actresses. Now, as I have shown,[33] amongst these very persons mixed ancestry, or miscegenation, is especially common too, commoner than in any other class of British notabilities. This special darkness of complexion in a northern race is, therefore, probably in the nature of a variation indicative of general abnormality. The same may be said of *red hair*, with the addition that it is a distinct atavism. In a source cited last was given a series of authorities, from Eusebius to Karl Pearson, connecting red hair with crossing of race, whilst it was recalled that primitive man was red-haired; also evidence from the Royal Albert Asylum, published in Pearson's monograph aforesaid, was cited, showing red hair in excess amongst imbeciles. Another point brought out was a close association of black hair with red. It is especially interesting, in view of Schmidt's "Haardisharmonie" (v.s.) in which sometimes the red tint appeared late, that the anthropologist Kohlbrugge[34] describes in Java apes of a species in which both red and black specimens occur, and which sometimes reciprocally change colour.

Ichthyosis is frequent in the insane[35]; according to my own comparison, about five times as frequent as in the sane. There are theories of its atavistic nature, advanced by Bowen and by Renshaw, whilst its great commonness in living tribes in Asia (Hirsch) and its being the normal condition in a locality in Europe (Allbutt and Rolleston) is further proof of its atavistic origin—and also of its not being tuberculous or tuberculo-toxic. Ichthyosis is also notoriously associated with malformations. *Nasal obstruction and mouth-breathing* commonly occur in idiots, especially the Mongolian variety, who almost all die of tubercle. *Polymastia* is a "theroid" arrangement of the milk glands, and in the male suggests feminism and bisexuality. Macalister[36] confirms Iwai that female subjects of polymastia are especially liable to multiple gestation, adding that they are also characterised by inability to metabolise much animal food. He thinks such inability, as also possibly dislike of fat, due to reversion to a primitive vegetarian diet habit. We recall that dislike of fat is reckoned common in the tuberculous and precedent to their disease. *Absence of beard* in males, and *abnormally shaped forehead*, are given by alienists (Marie, Voisin) as stigmata of degeneracy. Klapp's[37] explanation of *floating tenth rib* is that in man the lower ribs are not in morphological equilibrium, but are undergoing phylogenetic regression, from segmental shortening of the trunk originating in the assumption of the upright posture. This goes well with Stiller's aforementioned association of floating tenth rib with enteroptosis, for the phylogenetic explanation of the latter condition by Glénard and by Arbuthnot Lane, who connects it with tuberculosis, is familiar. *Double hair whorl* is another stigma of degeneracy given by French neurologists (Féré, &c.). *Pubic hair area of shape appropriate to the opposite sex* is obviously a mark of masculism or feminism, as the case may be, and thus of a condition common in the insane. It also points to bisexuality, a primitive condition. Likewise frequent in the insane are congenital *aural anomalies*. The form particularly mentioned, absence of lobule, is according to Darwin (l.c., p. 15), and the anthropologist Waitz,[38] normal to all primates except man, though gorillas possess a rudiment, whilst negroes often show an absence of lobule. Another bodily character of negroes—namely, musculature—is stated by the physiologist Luciani,[39] as also by Professor Keith,[40] to be more primitive than that of Europeans. Polanski gives figures to demonstrate *long reach in proportion to height* as a character of the lower primates, of uncivilised races, and of criminals.

Conclusion.

A few of the above characters, for example, cardiac hypoplasia, have been ascribed to persistence of a childish condition—that is, to infantilism. But this generalisation is obviously not inclusive enough. Lundborg's idea is that predisposition to tubercle is from degeneration due to "blood chaos" from race-mixture. This, again, is no doubt valid as a partial explanation, but atavistic reversion to a primitive susceptibility to tuberculosis (seen in uncivilised races) needs mention, whilst race-mixture can hardly be held universally responsible for tuberculous predisposition. I think its influence will be found operative only, or mainly, in certain cases. Thus of 175 juvenile consumptives I have notes of, 22 showed either squint, ichthyosis, red hair, or persistent lanugo. In these 22 there was one miscegenate (mixed race) to every seven; but in the remainder only one miscegenate to every 17. Again, the evidence for the influence of miscegenation is much more certainly established by the method here adopted, that of individual investigation, than by Lundborg's arguments from comparing the tuberculosis statistics of one country with another, which involves obvious fallacies; or from the prevalence of tuberculosis in a district at different periods, which may be due to many factors, say the introduction of industrialisation and urbanisation, with resulting development of individual or racial immunity: or from increase of *perlsucht* after native resistant cattle had been crossed, for here, as in India (Lankester) and Japan, the outcross was with tubercle-susceptible European stock, so that the offspring could have inherited liability to tubercle from one side of the pedigree, not developed it as the result of miscegenation. Still, Lundborg's work is valuable general corroboration. Polanski, perhaps, comes nearer the whole truth when he compares the diathesis of tuberculosis with that of several mental and nervous ailments. This leaves out predisposition by defect (e.g., nasal) which obviously increases opportunities of infection. The most sufficing and philosophic conception at present open to us would seem to be the recognition, as unduly frequent in tuberculous subjects of civilised races, of an hyper-variability, sometimes connected with miscegenation, miscegenation not with the uncivilised, but so to say inter se. Examples of crosses that I have encountered are English-Italian, English-German, English-Scandinavian, English-French, English-Irish, Scotch, or Welsh. Thus the consumptive of civilised race, compared with the rest of his community, is "less often in the mean, more often in the extreme."[15]

Practical deductions from all this as regards prophylaxis and diagnosis hardly need mentioning. What does need stress is the eugenic aspect—as regards tuberculous patients bodily degenerate, and without countervailing intellectual superiority.

A NOTE ON THE STORAGE OF VITAMIN A IN THE LIVER OF THE RAT.

By KATHARINE H. COWARD, M.Sc.
(BEIT MEMORIAL RESEARCH FELLOW),
JOAN L. LUSH,
AND
M. GRACE PALMER.
(From the Biochemical Laboratories, Institute of Physiology, University College, London.)

The occurrence of vitamin A in various glandular organs of the body has been reported by several investigators in this subject. Thus McCollum and Davis (1915) found it in pig's kidney and in cod's testicle; Osborne and Mendel (1917, 1918) found it in pig's kidney and in pig's liver; and McCollum, Simmonds, and Parsons (1921) in liver. Further, Zilva and Drummond (1922) found the fresh roe of various fish—especially the cod—and also ox liver to be valuable sources of the vitamin. Other reserves in the body are generally found in the fat, both subcutaneous and subperitoneal. No attempt was made to determine the minimum dosage of any particular tissue necessary to restore growth in rats which had become steady in weight on a diet deficient in vitamin A (the only means at present known of estimating the vitamin content). Hence the great variation in the concentration of this factor escaped the notice of these observers, and it was only when the influence of feed on the vitamin content of the milk of cows had been clearly demonstrated by Drummond, Coward, and Watson (1921) that it occurred to one of us that the vitamin content of the liver of any animal probably also varied considerably with the amount of the factor supplied in the food. It was decided, therefore, to investigate the influence of the diet of the rat on the storage of this factor in the liver.

Fig. 1.

In each figure the dotted line indicates the preparatory period on diet deficient in vitamin A.

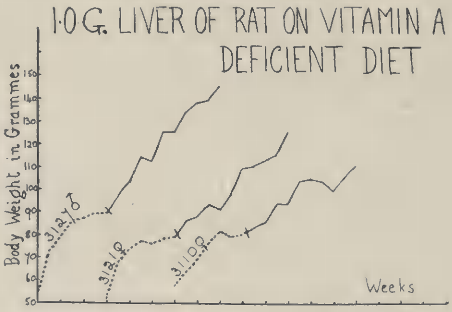

Fig. 3.

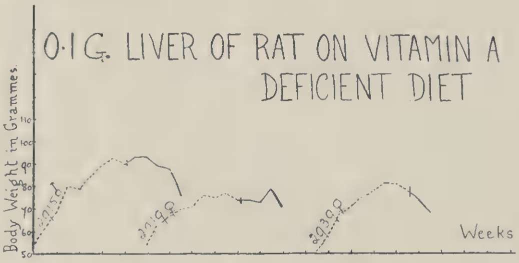


Experimental Method.

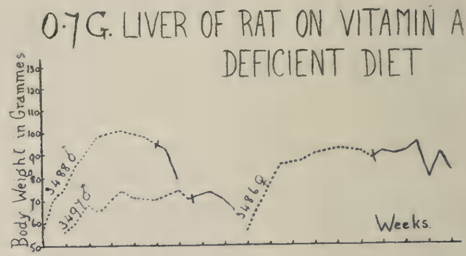
Test Animals.—Rats were prepared in the usual way adopted in this laboratory (Drummond and Coward (1920), and Coward and Drummond (1921)), and when they had become steady in weight, small doses of the livers of rats fed according to the description below, were given to them each morning before their daily ration of basal diet was put into the cage.

The Livers Used in Feeding.—One series of rats was fed on our basal diet deficient in vitamin A and only those rats were used which had remained steady in weight at 110–120 g. for about 14 days. The fresh liver was fed to the test rats in doses of 0·02, 0·1, 0·5, 0·7, and 1·0 g. respectively. A second series of rats was fed on a diet similar to the above, except that butter was substituted for the hardened cotton-seed oil, and the casein was not heated, as there was no object in destroying the vitamin. The dosage in this case was 0·1, 0·3, and 0·5 g. respectively.

Results.

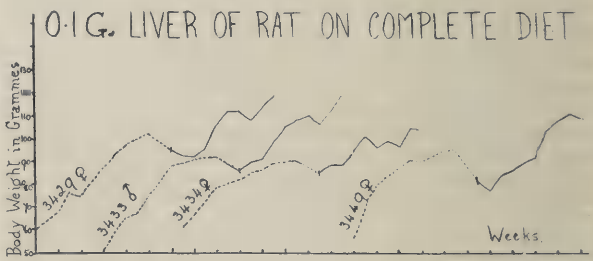
No growth was obtained on feeding less than 1·0 g. of liver of rats fed on the basal diet deficient in vitamin A (Figs. 1, 2, and 3). It is interesting to note the marked difference between the response to supplements of 0·7 and 1·0 g. The experiments of Zilva and Miura (1921) show that a certain concentration of the vitamin given to rats may have no apparent results, while a slight increase in the dosage may be sufficient to produce very marked results. In all cases where growth was not resumed, the general appearance of the rats remained poor, their coats were rough, and the majority showed marked symptoms of keratomalacia. Those rats, however, which received a supplement of 1·0 g. of these livers gradually returned to the condition of normal healthy animals.

Fig. 2.



In contrast to these results, good growth was obtained by feeding 0·1 g. of the liver of a rat fed on the vitamin-rich diet (Fig. 4). The general condition of the test animals improved very rapidly even on this small dosage. Cases of acute keratomalacia quickly cleared up, the coats of the rats became smooth and glossy, and the rats themselves were much more active. Higher doses of 0·3 and 0·5 g. gave very similar growth curves, so that it is probable that the minimum dosage required to give normal growth in this case is even less than 0·1 g.

Fig. 4.



Summary and Conclusion.

1. The concentration of vitamin A in the liver of the rat varies with the concentration of this factor in the diet.

2. On being deprived of vitamin A, the rat ceases to grow apparently before the store of vitamin in its liver is completely exhausted.

3. It would appear from this that a reserve is necessary for some function of the animal body other than growth.

NOTE.—Confirmation of the above has recently been obtained by testing the unsaponifiable matter of the livers of rats fed on a complete diet and that from rats fed on a diet deficient in vitamin A. Test-rats resumed growth on a daily dosage of 0·02 g. of the former, while an equal dose of the latter failed to show any growth-promoting power. Moreover, a test was carried out on the fresh livers of rats which had been fed on a deficient diet for much longer periods of time than those used in the first experiment; in fact, the livers were not used until the rats showed a definite decline in weight. 1·0 g. of the liver then completely failed to restore growth in the test animals, which would appear to indicate that the store of vitamin A retained in the liver on the cessation of growth is used up for some other purpose during the period when the rat remains stationary in weight.

WASSERMANN AND FLOCCULATION TESTS:

COMPARED IN 1000 CASES.

By A. L. URQUHART, O.B.E., M.B., CH.B. EDIN., D.P.H.,

LECTURER IN PATHOLOGY AT ST. THOMAS'S HOSPITAL, LONDON.

SINCE the work of Sachs and Georgi[1] appeared on the phenomenon of the flocculation reaction (F.R.) test as evidence of syphilitic infection, many working on similar lines have endeavoured to find a procedure which will give by the simple flocculation method results as accurate as those obtained by the more complicated Wassermann reaction (W.R.). The results of the many investigators who have utilised this method, or modifications of it, are at variance. For while some claim for it greater reliability than the W.R., others find that the method gives unreliable results.

In the hands of certain workers results have been obtained which compare very favourably with those of the W.R. Dreyer and Ward[2] by their Sigma reaction tested over a thousand sera and found

> "out of 386 cases of definite syphilitic infections the Wassermann reaction gave positive results in 327 cases, while the Σ reaction gave positive results in 381 cases. Thus the reaction gave positive results in 18 per cent. more cases than the Wassermann reaction. It only failed in five cases to reveal the presence of syphilis, while the Wassermann reaction failed in 59 cases."

Wang[3] in 200 cases tested, and Stokes and Whigham[4] in 1515 sera investigated found agreement in 96 per cent. of the tests. Perry and Lambkin,[5] following the method of Dreyer and Ward,[2] found agreement of 479 in 486 cases tested, seven cases giving discordant results. Collier[6] in 569 cases states that the Sigma test is more accurate than the W.R. In the following communication, in which 1000 sera have been tested, 98 per cent. of the results have been in agreement, 2 per cent. only giving divergent results.

Technique of the Flocculation Test.

The following technique has been adopted during these observations:—

1. The sera tested were obtained from syphilitic cases treated and untreated, suspected syphilitic cases, and from cases of diseases other than syphilis, including tuberculosis. All sera were taken with sterile precautions and inactivated at 58° C. for 20 minutes.
2. Alcoholic extracts of sheep's heart have been employed as antigens, to which cholesterol was added, and diluted with 0·85 per cent. sterile saline to 1–10.
3. The tubes and water-bath at 37° C. were those used for performing the W.R.
4. Dilutions of serum were made with a graduated 1 c.cm. delivery pipette in a watch-glass.
5. The readings were made after 24 and 48 hours' incubation at 37° C.
6. 1 c.cm. of diluted serum and 0·5 c.cm. of antigen were placed in each tube.
7. Readings were made against a dark ground with a + 6 hand lens.

To set up the test five tubes were taken. In a watch-glass 0·2 c.cm. of serum + 1·8 of 0·85 per cent. saline were mixed and 1 c.cm. of the 1–10 serum was placed in Tube 1. A further 1 c.cm. of saline was added to the contents of the watch-glass and 1 c.cm. of this 1–20 serum placed in Tube 2, and so on, Tube 5 containing 1 c.cm. of 1–160 serum. To each tube 0·5 c.cm. of antigen was added. The contents were mixed and the tubes placed in the water-bath at 37° C. for 24 hours. Control tubes of antigen and serum were also incubated.

Time of Reading the Reaction.

In the original Sachs-Georgi standard method readings were taken after two hours at 37° C., followed by 20 hours at room temperature, but in his later instructions of March 14th, 1922, Prof. Sachs recommends that the tube should be placed in the incubator at 37° C. over-night, and that readings should be taken on the following day. Readings are taken with the aid of a hand lens or with the agglutinoscope. Sachs states that in most cases reading is possible in three to four hours, but that the reading on the following day must not be omitted. Dreyer and Ward [2] recommend a period of seven hours' incubation in a water-bath at 37° C., followed by five to ten minutes' standing at room temperature.

With the antigen employed throughout this series, readings are noted at 24 and 48 hours, as it has been found that although in many cases positive readings could be obtained in seven hours when strongly positive sera were being investigated, yet in sera when the reading was recorded as + the reaction was not definite until after 24 hours' incubation, and in five instances only appeared during the second period of incubation. In these five cases the W.R.'s were also noted as weakly positive.

Method of Reading Flocculation Results.

The tubes at the end of 24 and 48 hours were removed from the water-bath, and readings taken with a + 6 lens against a small blackboard. The appearances were quite comparable to the degrees of agglutination present in typhoid agglutination, and all degrees of reaction occurred from complete sedimentation to a trace of flocculation. A + was noted against all tubes in which a reaction was observed, thus readings of from + to + + + + + were obtained, but the degree of flocculation might vary considerably in the sera which gave the reaction up to the same titre. Thus a serum which gave positive readings of "complete," "marked," and a "trace" of flocculation were noted as + + +, as would a serum reading "marked," "trace," "trace." Occasionally it was found that a zonular reading was obtained; thus Tube 2 might give a definitely heavier flocculation than Tube 1, and this phenomenon has been observed in readings of the reaction in other parts of the scale of dilution.

The readings of the flocculation test after 24 and 48 hours were usually similar in the number of tubes giving a reaction +, but the actual size of the floccules generally increased with the length of the incubation. It was, however, not uncommon to find that the titre to which the reaction had occurred in 48 hours was definitely higher than that which obtained at 24 hours, and it has already been noted that flocculation reactions in five instances only appeared after 48 hours' incubation.

The Wassermann Technique.

The W.R. of each of the sera was tested. For the hæmolytic system a 5 per cent. suspension of sheep's red cells sensitised with 6 minimum hæmolytic doses (M.H.D.) of hæmolytic immune body was used. In order to ensure that the centrifugalised red cells were suitably packed, and to obtain a constant suspension with each batch of reactions, the final washing of the red cells was prolonged for 15 minutes. The supernatant saline was then removed, and the amount of hæmoglobin present in 5 c.mm. of the packed cells was estimated with a Haldane's hæmoglobinometer. It was found in practice that well-packed cells gave hæmoglobin contents of from 105–110 per cent., and only red cells which gave such readings were used to make up the suspension. In each tube were placed 0·25 c.cm. of inactivated serum diluted to 1–5, 0·25 c.cm. of cholesterolised sheep's heart antigen, and 3 M.H.D. of complement contained in 0·25 c.cm. After an hour at 37° C. 0·25 c.cm. of sensitised red cells was added, bringing the total volume to 1 c.cm., and the results were read after a further incubation of 1 hour. The usual control tubes were employed. Those sera which gave a positive reaction were titrated in three further dilutions of serum. Tubes containing 1–10, 1–20, and 1–40 dilutions of serum were set up, and readings of + to + + + + were thus obtained.

Preparation of Antigens for the Flocculation Test.

The antigens used in this investigation were alcoholic extracts of sheep's heart, to which definite quantities of 1 per cent. alcoholic solution of cholesterol were added, the mixture being diluted with 0·85 per cent. saline to 1–10. The sheep's heart extract was prepared by a modification of that of Bordet and Rulen's[7] method used by Dreyer and Ward[2] in the Sigma reaction. One hundred grammes of finely-minced fresh sheep's heart was sprinkled with alcohol and dried under hot-air fans. The dried heart muscle was ground to a fine powder in a mortar, and to 20 g. of the powder 200 c.cm. of acetone was added. The mixture was placed in the incubator at 20° C. and shaken at intervals for six days. The acetone was then filtered off and a further 100 c.cm. of acetone added to the residue and treated in a similar manner for a further 24 hours. The acetone was then filtered off and the residue allowed to dry at room temperature. To the resulting dry powder in a well-stoppered bottle, 200 c.cm. of 96 per cent. alcohol were added, and the mixture shaken for three hours; the bottle was then placed in the incubator at 37° C. for 18 hours, and then further shaken for two hours. The alcoholic extract was filtered off into a flask which was placed in an ice-salt freezing mixture for four hours. Much fatty material was brought out of solution by this cooling process, and by rapid filtration this material was eliminated and a golden-yellow heart extract obtained; further deposit of fatty material did not occur.

Method of Preparing Antigen for Use.

Logan[8] noted that the readings of the precipitin test were difficult when the antigen was opalescent, but that with more opaque antigens the readings were more easily noted. Several opacities of antigen, obtained by varying the dilution of the alcoholic extract, were tested, and it was found that using the antigens prepared by the above method in 1–10 dilution satisfactory and easily read flocculation resulted. A hand lens was employed to determine the end-point of the reaction.

Sachs in his instruction of March 14th, 1922, when diluting his antigen, prefers to mix them by the following method: "To 1 part of antigen add quickly 1 part of 0·85 per cent. saline and shake for half a minute. Add quickly a further 4 parts of saline. The dilution thus prepared is opalescent, but is homogeneous and translucent."

This method of preparation was tried, but did not always give a satisfactory homogeneous antigen. Dreyer and Ward[2] recommend dropping the saline on the alcoholic extract from a constant height at a constant rate, and it has been found that a homogeneous translucent antigen appears to be most readily obtained by dropping the saline on to the alcoholic extract. A 50 c.cm. burette was used for this purpose, and by dropping the saline on the extract from a height of 6 inches a satisfactory homogeneous antigen was obtained.

The Cholesterol Content of Sheep's Heart Extracts.

The first antigens used were mixed in the following proportion: 0·6 c.cm. of heart extract and 0·4 c.cm. of a 1 per cent. alcoholic solution of cholesterol were placed in a 6 by 1 test-tube and 9 c.cm. of sterile 0·85 per cent. saline were dropped on the alcoholic mixture. With this antigen flocculation occurred with syphilitic serum, but it was found that the titre of the serum tested varied considerably with antigens prepared from other sheep's hearts and made up by the same formula. Each heart extract was then tested on several positive sera, using different proportions of extract and cholesterol, the total alcoholic content remaining unchanged (1–10). It was found that an optimum addition of cholesterol could be made, by which the highest and most clear-cut readings were obtained. This proportion of extract to cholesterol varied in the different antigens. Thus five antigens were made from extract No. 2 containing varying proportions of extract and cholesterol. All were made up to 1–10 with saline. Each of the five antigens were tested against several syphilitic sera, and the antigen which gave the highest and most clear-cut readings was noted. The amount of cholesterol added to this particular antigen was considered the optimum for the heart extract.

In Table I. the figures for extract No. 2 with the readings at 48 hours are tabulated.

TABLE I.

Extract No. 2 tested on a syphilitic serum. Five antigens prepared, containing varying proportions of extract and cholesterol in 1–10 dilution.

Heart ext. (c.cm.).	1 % cholesterol (c.cm.).	Dilutions of serum.				
		1–10	1–20	1–40	1–80	1–160
0·6	0·4	IC	M	Tr.	Tr.	–
0·7	0·3	IC	IC	M	Tr.	–
0·8	0·2	IC	IC	IC	M	Tr.
0·9	0·1	C	C	IC	IC	M
1·0	Nil	C	IC	M	Tr.	–

C, Complete. IC, Incomplete. M, Marked. Tr., Trace. –, No reaction.

The reactions occurring with this serum show that those obtained by using this heart extract in the proportions of 0·9 c.cm. of extract, 0·1 of cholesterol in 9 c.cm. of saline gave the most powerful and clear-cut results. Both above and below that concentration the reaction was definitely weaker. In conjunction with results obtained from other sera also this No. 2 extract was found to give the best results when used in the above-mentioned proportions.

Similarly, the five remaining antigens were tested and it was found that the optimum addition of 1 per cent. cholesterol for these extracts varied to considerable extent. In Table II. are noted the optimum dilutions for the six antigens prepared and employed in testing 1000 sera.

TABLE II.

Antigen.	Heart ext. (c.cm.).	1 % cholesterol (c.cm.).	Saline 0·85 % (c.cm.).
1	0·6	0·4	9
2	0·9	0·1	,,
3	0·8	0·2	,,
4	0·8	0·2	,,
5	0·7	0·3	,,
6	0·7	0·3	,,

When the heart extracts were tested on syphilitic sera, after the optimum cholesterol addition had been made, the readings obtained by the flocculation test were of similar titre, and thus comparative results could be obtained with any of these antigens. These antigens are still in use and are giving satisfactory results, some of them being more than a year old. It would appear, therefore, that either the amount of cholesterol present in sheep's heart muscle varies with different animals, or the amount extracted from the muscle by acetone and alcohol varies. By adjusting the amount of 1 per cent. alcoholic solution of cholesterol to a suitable proportion closely approximating readings may be obtained with any heart extract made by this method, but without this preliminary experimentation to find the optimum cholesterol addition, no comparative readings of the flocculation test can be made.

Granularity in the Flocculation Test.

In a certain number of flocculation tests in which negative W.R.'s were recorded a slight granularity of the antigen was noted after incubation. This granularity was not observable by the naked eye, but showed when the tube was examined by the hand lens. In these tubes definite flocculation had not occurred, but when the control tube and the test tube were examined side by side the granularity was quite apparent. Similarly, when negative sera were examined in dilutions lower than 1–10 this granularity frequently appeared. In reading the tests, therefore, tubes showing this granular condition must be regarded as negative or "false positive" readings will be recorded. There is, however, little difficulty in distinguishing this granular condition from flocculation. This appearance in the tubes rarely occurred in dilutions of 1–10 or over. It was also noted in some of the antigen preparations containing more than the optimum amount of cholesterol, that shimmering crystals appeared during or even before incubation. These crystals at first gave the appearance of flocculation in the tubes, but were easily distinguished from true flocculation by the hand lens. In no case was this crystalline deposit observed when the antigen was made up containing the optimum or less than the optimum amount of cholesterol.

The Comparative Results of the Flocculation and Wassermann Reaction Tests.

Of the 1000 sera tested the following analysis may be given:—

TABLE III.

Analysis of 1000 sera compared by the Wassermann and flocculation tests.

Fl. + W.R. +	Fl. − W.R. −	Fl. − W.R. +	Fl. + W.R. −	Percentage of divergent results.
221	759	10	10	2 % = 20 cases.

The sera investigated were obtained from various sources: (*a*) From persons suffering from untreated syphilitic infection; (*b*) from persons suffering from syphilitic infections who were under treatment; (*c*) from persons suffering from suspected syphilitic infections; and (*d*) from persons suffering from acute and chronic diseases in which syphilitic infection was not present.

The (*d*) group of cases formed the majority of the sera tested, as it is important to ascertain whether non-syphilitic conditions, acute or chronic, will give "false positive" results with the flocculation test. It would appear, however, that such is not the case. Of the 1000 sera tested by the W.R. 231 gave a positive reaction and 769 negative. The same sera tested by the flocculation test differed in 20 instances, or 2 per cent. Of these 20 cases, 10 gave a negative flocculation test when a positive W.R. was noted, and in 10 cases where a positive flocculation was recorded the W.R. was negative.

The titre to which the sera of untreated cases of syphilis reacted by either method of testing corresponded to a marked degree, weak positive W.R.'s corresponding to weak positive flocculation reactions, and strongly positive ones to strongly positive. This similarity in titre can hardly be more than commented upon, in view of the dissimilarity of the two tests—complement fixation on the one hand, and a precipitin reaction on the other; but it is of interest to note that these results have been obtained in the sera of syphilitic persons who have not received treatment, and that this agreement between the two methods of examination has held throughout the series.

In Tables IV. and V. the details of the cases giving divergent results by the two methods of testing are noted with the clinical diagnosis.

TABLE IV.

Cases in which positive W.R.'s but negative F.R.'s were present.

No.	Diagnosis.	W.R.	F.R.	No.	Diagnosis.	W.R.	F.R.
1	Child. Congen. syphilis	+ + +	−	7	Tertiary syphilis	+	
2		+	−	8		+	−
3		+	−	9	Brachial neuritis	+ + +	−
4	Tabes	+	−	10	Hæmorrhoids	+ +	−
5	Primary syphilis	+ +	−				
6		+	−				

− = No reaction. + = Positive reaction.

TABLE V.

Cases showing negative W.R. but positive F.R.

No.	Diagnosis.	W.R.	F.R.
1	Child, congenital syphilis	−	+
2		−	+
3		−	+
4		−	+ +
5	History of stillbirths	−	+ + +
6	Aortic regurgitation	−	+
7	Intracranial tumour	−	+
8	Primary syphilis	−	+
9	Interstitial keratitis	−	+
10	Jaundice (hæmolysis)*	−	+ +

* In case No. 10 of this list a very considerable degree of hæmolysis occurred after the serum had been in contact with the clot for some time and the positive reaction was probably due to presence of the hæmoglobin in the blood serum.

In each of these Tables IV. and V. it is seen that although in the majority of these exceptions in which divergent reactions were recorded the positive reaction was present only as a + reaction, yet cases occur in either list of sera giving a + + or + + + reaction by one method and failing to give any reaction by the alternative test.

Result of Treatment on Comparative Results of the W.R. and F.R. Tests.

In cases of syphilitic infection which had received treatment the correspondence in titre which was found in the untreated cases did not hold. The F.R. test readings frequently were one + or more stronger than those of the W.R. Thus in 50 cases of syphilitic infection in which treatment had been given, 19 only showed correspondence in titre, while in 31 the F.R. test gave considerably stronger readings than the W.R. In no case under treatment did the W.R. reading exceed that of the F.R. test. In only a few instances has the same patient been examined on more than one occasion, and few consecutive tests on individuals under treatment have been made. These findings, therefore, would suggest that the F.R. does not disappear from the sera in cases of syphilitic infection so rapidly as the W.R.

The Flocculation Test in Cases of Tuberculosis.

The sera of 18 cases of tuberculosis were tested in which the tubercle bacillus was demonstrated in the sputum. In 17 cases negative reactions were recorded by both the W.R. and F.R., while in one case both the W.R. and F.R. were noted as +, but further information as to a history of syphilitic infection was unobtainable.

The Presence of Hæmoglobin in the Blood Serum.

Fifty-one of the sera tested showed definite degrees of hæmolysis. In 12 of these cases a positive W.R. and F.R. occurred. In the remaining 39 sera the W.R. was negative, and 32 of these gave negative F.R. tests; of the remaining 7 cases 5 presented a floccular appearance in the tubes, and in 2 a very definite reaction occurred, the amount of colouration in the serum in these last 2 cases was considerable. It would appear, therefore, that negative results where hæmoglobin is present in the serum are reliable, but positive readings are not to be relied upon as "false positive" readings may be recorded.

Contamination of Serum Used in the Flocculation Test.

The blood for the F.R. test was usually obtained by venepuncture and was taken with the usual sterile precautions. In a certain number of cases, however, contamination had occurred, and it was found that during the long incubation at 37° C. the organisms grew and gave the appearance of flocculation in the tubes. In cases where the growth was massive the error was easily detected, but where less luxuriant growth was encountered the true reading of the results was much more difficult. Such results from contaminated sera have not been included in the series. It is of importance that the sera tested should be sterile, as "false positive" readings will otherwise be recorded. The serum control in the test will give evidence of such contamination. Dreyer and Ward[2] note that if a serum obviously infected gives a negative reaction the reaction may be accepted as valid, but all positive reactions in infected sera must be discarded and further specimens examined.

The Presence of Bile Pigment in the Serum.

Eight of the sera tested contained bile pigment. Of these three gave positive reactions by both tests, and the remaining five negative reactions. It would appear, therefore, that the presence of bile pigment in the serum does not interfere with the F.R. In one case noted in Table V., in which bile pigment was present, a positive F.R. was noted, but a considerable degree of hæmolysis had also occurred which was probably responsible for this result.

Anticomplementary Serum.

Five anticomplementary sera were tested during the course of these observations. In each of them the true reading of the W.R. was negative, as was the F.R. The anticomplementary state of blood serum does not appear to affect the F.R. test.

From these observations it would appear that using antigens prepared by the above method the F.R. test yields satisfactory evidence of syphilitic infection; and there is a large mass of evidence in the work of others to show that the original Sachs-Georgi test, or Sigma test, or modifications of these methods are capable of giving results as satisfactory as those of the more complicated W.R. In the above series of 1000 tests a lack of agreement between the findings of the two methods occurred in only 2 per cent. of the cases.

Conclusions.

1. That the flocculation test gives as reliable results as the Wassermann reaction.
2. That the flocculation test is preferable to the Wassermann reaction on account of its greater simplicity.
3. That sheep's heart extracts make satisfactory antigens, and that similarity of antigenic property may be obtained by adjustment of the amount of cholesterol added to the heart extract.
4. That contamination or hæmolysis in the sera may give rise to false positive readings and such sera should not be used in the test.
5. That the presence of bile pigment, or an anticomplementary state of the serum does not interfere with the flocculation test.

SYPHILIS TRANSMITTED TO THE THIRD GENERATION.

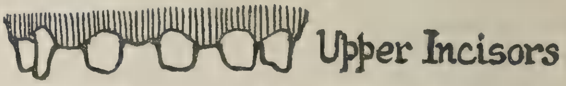
BY C. F. T. EAST, B.M., B.CH. OXF., M.R.C.P. LOND.

IN the seventeenth century van Helmont[3] thought that syphilis might be transmitted to the third generation. Sanchez[5] expressed the same view in the eighteenth century. On the continent of late years the idea has found much support. Barthelémy[1] was in favour of it being possible. Fournier[2] has urged strongly that the transmission of congenital syphilis undoubtedly does occur, and has collected a number of cases. In Germany Schultz[6] has supported this view. Sir Jonathan Hutchinson,[4] however, did not agree with this, and Dr. G. F. Still[7] considers the question undecided. The case about to be described would appear strongly to support the evidence that congenital syphilis can be transmitted to the second generation. It is therefore thought worthy of record.

A young woman, aged 23, was brought to hospital complaining of inflammation of the eyes. She had very typical interstitial keratitis, which she said had begun about six weeks previously. The right eye was more affected than the left. There was a history of eye trouble of a similar nature when she was 8 years old; this had subsided under treatment. Her mother said that she had been perfectly healthy as a baby; apart from the usual childish ailments, the keratitis was her only illness.

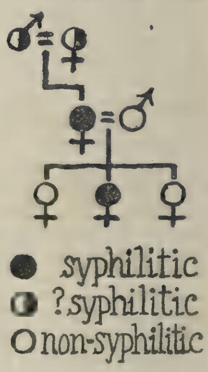
Condition on Examination.—There were traces of pigment on the anterior surface of the lens capsule in the left eye; otherwise the media, choroid, and retina of each eye were normal. There were no changes in the bones showing congenital syphilis and no scars at the angles of the mouth. The hearing was good. The condition of the teeth is best shown by the accompanying diagram (Fig. 1.) She seemed a normal, well-grown, healthy young woman. The Wassermann reaction (W.R.) in her blood was strongly positive.

FIG. 1.



Family History.—Her two sisters, 28 and 17 years old, were also examined. Neither of them had any trace of congenital syphilitic lesions; in both W.R. was negative. Their father said that he had never had any venereal disease and he showed no trace of any syphilitic lesion; nor was there anything in his history to suggest that he had ever had syphilis. His W.R. was negative. The patient's mother said that she had never had a miscarriage. It was noticed that the cornea of the mother's left eye had unmistakably the scars of an old interstitial keratitis. She had an external strabismus in this eye. In other respects her eyes were normal. Her teeth were typically Hutchinsonian. The arch of the palate was high; there were no scars at the mouth-angles; the bridge of the nose was normal. The bones of the skull and the tibiæ showed no abnormality. She said that when 6 years old she had had eye trouble. She had had treatment for this, and it had got better. The trouble had recurred about the time of the birth of the patient, when her eyes had been acutely inflamed. The W.R. in her blood was strongly positive. She said that she had always been well, and looked a strong, healthy woman. She was an only child, her father had been a soldier on foreign service, dying of "senile decay" at the age of 71. Her mother had died many years ago. As far as she knew there had been no miscarriages. The history of the family is tabulated in Fig. 2.

FIG. 2.



As far as a negative can be proved I think we may reasonably exclude the father of the patient as a factor. It would seem, then, that we have here as clear a case as possible of a woman suffering from congenital syphilis and passing on the disease to her daughter One may suspect that the soldier grandfather, who had seen much foreign service, originally introduced the syphilitic infection into the family. It seems an interesting point to notice that the lesions in the daughter reproduce so faithfully those found in the mother. It may be noted also that the eldest and youngest daughters escaped the infection apparently; while the second child, to whom the disease seems to have been transmitted, was born about the time that the mother had what was evidently a recurrence of her interstitial keratitis.

A TECHNIQUE OF SPINAL ANALGESIA FOR LAPAROTOMY

BY S. A. LANE, M.D. DUB.,
SURGEON, BOGNOR WAR MEMORIAL HOSPITAL.

THE purpose of this paper is to describe a technique of spinal analgesia for laparotomy whereby the patient undergoes operation, returns to bed and "comes to," unaware that operation has taken place. Granting this objective, it may fairly be claimed that the advantages incident to spinal analgesia will have been attained and the objections usually urged against the method eliminated. The first two of my patients to undergo operation in the above manner were both women aged 64; the one had a twisted ovarian cyst and the other a strangulated hernia; both patients were entirely unaware of having undergone operation, and the second patient remained incredulous until the following morning when a silkworm gut drain was removed.

I here describe an endeavour, made during the past year, to achieve this end in every case. The favourable results obtained have encouraged me to write this paper. The details of technique are sufficiently important to make a full account desirable. The surgeon and theatre staff should constitute a team well acquainted and thoroughly conversant with all details; failing this, the results are likely to be mortifying. The scope of analgesia includes all abdominal procedures.

Procedure before Operation.

The hour of operation is withheld from the patient unless he especially asks to know this. Three-quarters of an hour before operation any manipulations likely to disturb (e.g., passing a catheter) are attended to. The patient is settled comfortably on the trolley which takes him to the theatre, and is, if possible, placed in a quiet room. A hypodermic injection is given containing hyoscine 1/100, morphine 1/6, and atropine 1/150 (B. W. & Co.'s Hyoscine Compound A), the ears plugged with wool soaked in olive oil, and the disturbing influence of light and sound excluded as far as possible. Ten minutes before operation the condition is observed; if asleep or very drowsy, well and good. If not, a further hypodermic injection is given of hyoscine 1/450. Smoked glasses or goggles are put on before the patient is wheeled into the bright light of the theatre. The surgeon is washed up and ready as the trolley enters. The patient is made to sit up, and is drawn forward by a nurse standing at the foot of the table. It is an advantage to lower slightly the foot end of the table, whilst it is important that the patient be not too far down the table, as this produces involuntary hollowing of the back.

On withdrawal of the needle the puncture is quickly covered with collodion gauze and the patient lowered into the Trendelenburg position, to the extent of 30° with the least possible delay. The surgeon can then proceed to wash up again, whilst with a pin the "anæsthetist" tests the level of analgesia, watching the patient's face, but never speaking until analgesia reaches the lower costal margin. The table is then brought level unless a Trendelenburg position is required. The "anæsthetist" tests to see if analgesia goes to the nipple level, and if this happens the table is put level. The patient's wrists are now quietly tied in such a way as to prevent his having a hand in the operation.

Sleep usually comes quickly after the spinal injection. If not, the smell of ether on a mask, if thought desirable, is soon followed by sleep, and the eyes are covered. Conversation and noise are restricted as far as reasonably convenient, the impulses therefrom not being "blocked" save for the ear-plugs.

Indications for General Anæsthesia.

Should any indication for a "general anæsthetic" arise it is given at once. Shipway's warm vapour apparatus was found very good, it being always easy to get the patient quickly "under" with so small a quantity of ether that few, if any, of the unpleasant after-effects were produced. The indications for "general anæsthesia" noticed were in this order: (1) straining, if it embarrassed the operator; (2) returning sensation; and (3) returning consciousness. The patient ought never to realise operation is going on for want of a little ether.

Remarks.

The effect of the above procedures is to mitigate to a considerable extent pre-operative anxiety and so to bemuse the faculties that the patient goes to the operation oblivious of his surroundings and proceedings, acquiring a complete "nerve block" of the operation field, and maintaining unconsciousness throughout by the avoidance of disturbing stimuli, and, when necessary, by recourse to general anæsthesia in the small amount found adequate.

The great immunity from complication and accident in cases treated on these lines shows the method to be extremely safe. There was no case of collapse among any of the laparotomies, and only one in a series of about 70 spinal anæsthetics. This occurred in an ex-soldier during an amputation of a toe, and occasioned only a short delay. There has been a complete absence of "stovaine headache." In marked contrast to this is the experience of the writer when at a casualty clearing station in France, where, in a series of over 400 spinals, severe headache was rather the rule and collapse of varying degree not infrequent. The ordeal of operation was, undoubtedly, much less formidable than with general anæsthesia. A member of the theatre staff, who underwent subtotal hysterectomy, asked for "spinal," and later stated she did not regret having done so.

In addition to what has been said, the following points deserve emphasis: 1. Absence of risks and results peculiar to general anæsthesia, and apparently so even though recourse be had to it later. 2. Absence of post anæsthetic vomiting. 3. In critical cases no need for undue haste to "save the anæsthetic." One can count on 45 minutes anyway. The patient gains by an efficient operation rather than suffers from a prolonged one. 4. Increased ability to undergo prolonged operation and a much improved prognosis in many critical conditions. 5. Ability to take water or glucose solutions by mouth after operation instead of rectal saline.

The following were cases unaware of operation after returning to bed, and in whom no vomiting occurred after operation: (*a*) gastro-jejunostomy and appendicectomy; (*b*) subtotal hysterectomy; (*c*) intraperitoneal shortening of round ligaments and appendicectomy; (*d*) short circuit for irremovable carcinoma of splenic flexure; (*e*) hernia, during which the presence of large vesical calculus was verified; the same patient a fortnight later underwent suprapubic cystotomy for removal of calculus.

The preparatory doses of hyoscine have not exceeded two in number so far, and hyoscine was not used for patients under 16 years of age. The spinal solution used is stovaine and glucose 5 per cent. (Allen and Hanburys), and a 2 c.cm. dose was employed for adults.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF THERAPEUTICS AND PHARMACOLOGY.

The Present Position of Organotherapy.

A meeting of this section of the Royal Society of Medicine was held on Jan. 9th, Dr. **Langdon Brown**, the President, being in the chair, when Prof. **Swale Vincent** opened a discussion on this subject.

The Physiological Aspect.

He said that it was sometimes maintained that in therapeutics, as in other matters, only those methods which were found useful and beneficial would ultimately survive. In the employment of various substances to relieve pain, however, or to restore to the normal the deranged machinery of life, it would seem that we cannot even yet trust either the scientific discrimination of medical men or the commonsense of the general public to eliminate the useless and to hold fast to that which is good. At the present time many physicians, said Prof. Vincent, are habitually prescribing preparations derived from the various ductless glands, from digestive glands, reproductive organs, prostate, mammary glands, and less frequently from nervous, muscular, and other tissues. The belief in the efficacy of all these substances was based on a widely current view that all organs and tissues manufactured and poured into the circulation substances whose function it is to regulate the activities of different parts of the nervous system and to influence the general metabolic activities of the animal economy. The untenable hypothesis that the secretion of the chromaffin tissue maintains, or helps to maintain, the tone of the blood-vessels, and the normal blood pressure has given rise, for example, to the whole fabric of vagotonia and sympatheticotonia. When it became clear that physiological experiments lent no support to these views, a large number of physicians defended the use of organic extracts on the grounds that though they may contain no physiologically active principle, they are found useful empirically. This attitude was difficult to criticise on a priori grounds, because some few cases might be adduced where the value of a drug had been discovered by purely empirical means; but in the majority of these cases it had been possible at a later date to correlate the observed therapeutic value with a definite pharmaco-dynamic action subsequently discovered. It would be difficult to mention a drug of proved value in the treatment of disease which possessed no known pharmaco-dynamic effects. In organotherapeutics a large number of substances were commonly recommended for administration by the mouth, which as far as could be ascertained by careful experiment produced no physiological effects when given in this way. When such extracts were administered subcutaneously or intravenously, however, into dogs or cats mild transient stimulant or irritant action was produced. Intravenous injection of tissue extracts might produce lowering of the blood pressure and certain other changes. These effects, however, were not specific. No serious attempt had been made to correlate these physiological actions with any kind of therapeutic action, the extracts given medicinally being recommended for reasons quite independent of their physiological action. In addition to the acknowledged value of the thyroid and the posterior lobe of the pituitary, there might be a few instances where feeding with an organ for a prolonged period might produce some effect upon the rate of growth in young animals, or even upon the growth of special organs or tissues. Thus adrenal substance (cortex) when administered to a young growing animal seemed to induce a growth of the testis greater than in the control animals. Prof. Vincent did not, however, believe that there were many such instances. The difficulty of estimating the effect of treatment was not confined to organotherapy. In any branch of therapeutics it was difficult to decide whether the recovery of a patient was due to the treatment or whether it occurred in spite of the treatment.

Prof. Vincent proceeded to consider the therapeutic value of extracts from various gland substances.

Thyroid Medication.—Prof. G. R. Murray had discovered in 1891 that the administration of thyroid substance cured myxœdema, and up to the present time thyroid material had proved to be one of the most satisfactory drugs at our disposal. Thyroid extract, and its active principle, thyroxin, brought about an increase of the total metabolism of the body, the effect being most marked where there was a deficiency of thyroid secretion. Prof. Vincent laid stress on the value of thyroid preparations in myxœdema, cretinism, and in lesser degrees of hypothyroidism; in some cases of goitre thyroid was useful, but iodides were more efficient in the hands of many physicians. In obesity thyroid medication had been found useful when carefully applied. It was conceivable that in so far as this extract stimulated the chemical activities of the body it might be of value in a variety of conditions, and if there were any good to be obtained from the so-called polyglandular preparations this was probably attributable to the thyroid substances contained in them.

Parathyroid Medication.—In tetany some good results had been reported, oral administration being less beneficial than implantation. There was no satisfactory evidence that any form of tetany, except that following operations upon the thyroid and parathyroids, was due to a lesion of the last-named bodies. It seemed certain that tetany was a name applied to a condition which might arise from a great variety of causes.

Pituitary Medication.—It had never been shown that treatment by pituitary extracts had the slightest effect in remedying the symptoms thought to be due to pituitary insufficiency. Recent work suggested that many, if not all, of the symptoms formerly attributed to lesions of this organ were in reality the effects of injury to the hypo-thalamus. Posterior lobe preparations had been found useful in the treatment of polyuria, to aid uterine contractions, and to stimulate smooth muscle fibre elsewhere, as in the intestine. These uses of posterior lobe preparations had, however, no bearing on the functions of the organ; they were not instances of a substitution therapy.

Adrenal Medication.—The well-known value of adrenalin bore a very problematic relation to the function or functions of the adrenal body as a whole, or to the services possibly rendered to the animal economy by the chromaffin tissues. Here again it was not a question of substitution therapy. In Addison's disease adrenal preparations did not seem to be of the slightest value. Adrenalin produced no effects when given by the mouth, unless it were on the lining membrane of the stomach.

Testicular and Ovarian Medication.—It was doubtful whether these extracts produced the slightest effect when administered by the mouth. As to the testis, Prof. Vincent referred to the methods of Steinach and of Voronoff, stating that it was too early to appraise the value of these rival claims, or to express a positive opinion as to the results which might be expected to follow either of the methods. With reference to grafting, he pointed out that unless blood-vessel suture was employed, grafting was at best a temporary expedient.

Pancreatic Medication.—Hitherto the administration of pancreatic extracts had not proved of any value in the treatment of diabetes; but though it was not wise to be too sanguine, a step in advance had undoubtedly been made by the Toronto workers in the production of insulin. Dr. Mackenzie Wallis claimed to have prepared a pancreatic extract which was effective when given by the mouth. Prof. Vincent summed up the position of organotherapy in the following words:—

"If we seek for cases where it is possible to apply a true substitution therapy and artificially to replace the internal secretion of a gland, we have no clear instance except the solitary one of the thyroid. It may be that we shall before long be enabled to include the pancreas in the category. There are, however, some few instances where extracts of organs, or purified chemical substances obtained from them, are valuable as drugs, apart altogether from the question of internal secretion. Such are adrenin and extracts from the posterior lobe of the pituitary body. Of the rest of the gland and tissue extracts and preparations it might perhaps be well to say nothing, if it were not that their exploitation on the present-day scale may constitute a formidable kind of quackery. There is no subject upon which so much utter nonsense has been talked as upon internal secretion, and organotherapy, or at any rate a large part of it, may be defined as the application of this nonsense to practical medicine. In the meantime, certain forms of manufacturing druggists are making the most of a unique opportunity, and are growing rich by reason of the inadequate education of medical practitioners and the notorious ignorance of the general public on all matters relating to their own bodies."

The Therapeutic Aspect.

Prof. G. R. **MURRAY** said that certain lines of treatment by organotherapy were based on sound physiological principles and had proved of great value. Unfortunately owing to the enthusiasm of some speculative writers a great deal of ephemeral literature had appeared, much of which was of no value, and some of which had been positively harmful. The term organotherapy should be confined to the employment of the products of the excretory, secretory, and incretory glands in the treatment of disease. Other tissues should be regarded as foods rather than drugs. The excretory glands did not promise much help in this direction. Urea had well-known uses in medicine, and was a substance which, though not produced by the kidney, was excreted by it. Pepsin and pancreatin were principles of the secretory glands; their value was well known. Prof. Murray proposed to confine his remarks to the conditions in which treatment by incretory or endocrine glands was of proved value.

Thyroid Gland.—This gland contained at least one active hormone—thyroxin—of which the composition was known. Fortunately thyroid hormones could be absorbed unaltered in activity from the alimentary canal. The most important use of these preparations was to supplement a failing thyroid gland. In cases of the lesser degree of hypo-thyroidism, as indicated by mild cretinism in the child and slight myxœdema in the adult, doses of ♏v. of liquor thyroidei, or gr. ii. or gr. iii. of dry thyroid extract daily would be followed by steady improvement. In the later stages of thyroidal atrophy larger doses produced equally successful results, provided no incurable degenerative change in any other organ was developed. There was a latent period of a week or more before any definite effect could be observed. Kendall had shown that after a single injection of thyroxin in a case of myxœdema there was a latent period with a slow increase of reaction which reached a maximum at about the tenth day and persisted from five to seven weeks. Boothby had calculated that in order to maintain the normal basal metabolic rate 12 to 14 mg. active thyroxin must be present in the body, and that the thyroxin is used up at the rate of about 0·5 mg. a day. In order to maintain a normal basal metabolic rate in a fully developed case of myxœdema, it would require a daily intravenous injection of this amount of thyroxin. A larger amount would be necessary when given by the mouth. Plummer and Boothby estimated this at about 1·5 mg. daily. From clinical observations of cases over several years, Prof. Murray estimated the equivalent amount of liquor thyroidei (B.P. 1898) to be ♏x. or gr. v. of fresh gland, as this was a sufficient daily dose to maintain health after complete atrophy of the thyroid gland. In the treatment of simple parenchymatous goitre without symptoms of hyperthyroidism, a daily dose of gr. ii. of thyroid was often very useful. Since the thyroidal hormone was a powerful stimulator of metabolism, its use was beneficial in certain diseases of the skin, for example, psoriasis, and in the treatment of chilblains. In simple obesity thyroid was seldom beneficial unless combined with a suitable diet, and in any case must be used with caution. In some menstrual disorders and in nocturnal enuresis quite small doses had been found useful by various observers. The good results described in tertiary syphilis were due probably in part to the iodine contained in thyroxin and in part to the stimulation of metabolism. The thyroid hormones were evidently stimulators of intestinal peristalsis, and relieved some forms of constipation.

Parathyroid Glands.—There seemed to be good reason for the view that these glands neutralised or prevented the formation of guanidine, excess of which was probably a cause of tetany. According to Dr. H. Vines these glands were also concerned with the regulation of calcium metabolism.

Suprarenal Glands.—It was known that Addison's disease was due to a destructive lesion of the suprarenal glands. It was also known that adrenalin could be extracted from the medulla of these glands, but there was a large gap in our knowledge between these two observations. Prof. Murray had never seen permanent improvement take place in a case of Addison's disease following on the administration of any preparation of the adrenal gland. It was probable that in the few recorded recoveries the symptoms had been due to the loss of one suprarenal gland, and recovery to the development of a compensatory hypertrophy of the other. The right way of supplementing adrenal deficiency had not yet been found. Adrenalin, however, was a well-known remedy in the treatment of shock, in the treatment of asthma and œsophageal spasm, and locally in arresting hæmorrhage.

Pituitary Gland.—What had been said of the suprarenal gland applied largely to the pituitary gland; assuming that adiposo-genital dystrophy was due to the loss of pituitary hormones, we were unable to remove the signs of this disorder by giving glandular preparations. The value of posterior pituitary extract as a uterine stimulant in paralytic distension of the bowel and as a temporary cardiac stimulant in acute disease was recognised.

Gonads.—There was little satisfactory evidence to show that either testicular or ovarian preparations had any therapeutic action when injected or taken by the mouth. The reported relief of subjective sensations was not sufficient evidence. A true test, for example, would be success in making the eunuch grow a normal amount of hair on the face.

Prof. Murray said that the discovery of a method of making an efficient extract of the islands of Langerhans suggested that further researches might yield new and useful therapeutic agents from the endocrine glands, and teach us how best to employ those already in our possession. He concluded: "In summarising the present position of organotherapy we may certainly claim that in preparations of the thyroid, parathyroid, pancreas, suprarenal, and pituitary glands, we possess agents of proved value. In the case of other endocrine glands, while recognising the importance of their functions, we cannot fairly claim that we as yet know how to obtain or employ active preparations made from them. To those of us who have devoted attention to endocrinology for many years, the recent exploitation of organotherapy for all kinds of diseases is deplorable, as it is apt to discredit a valuable means of treatment when properly employed."

Dr. W. R. **GROVE** described cases of long-standing varicose ulcers in patients showing deficiency of calcium in the blood as estimated by Dr. Vines. These ulcers had improved greatly under intramuscular injections of calcium. In some cases the calcium content of the blood could not be raised to normal. To these parathyroid gland was given in 1/10 gr. dose daily; the blood rapidly became normal in calcium content and the ulcers healed completely. They concluded that parathyroid extract was capable of influencing calcium metabolism, and that with normal calcium content of the blood healing speedily occurred. Cases which did not progress were found to have a primary septic focus, such as pyorrhœa, and when this was removed they improved greatly. Dr. Grove quoted a large number of cases of gastric and duodenal ulcer, phlebitis, diseases of the rheumatic group, and many other diseases of septic origin in patients whose blood was deficient in calcium; these, he believed, had improved greatly under parathyroid therapy. He concluded that parathyroids had a definite remedial action in all the chronic diseases accompanied by a calcium deficiency, which is simultaneously improved or brought to normal. He regarded parathyroid extract as a physiological aid to the healing of chronic lesions due to toxic absorption. If the focus of the toxin were removed parathyroid would then—and then only—bring about a cure, and was a valuable remedial agent.

Dr. H. Vines said that in all the various diseases improved by parathyroid therapy the underlying condition was sepsis. In some cases where the white blood count had been low, the full polymorph count rose to 18,000 in two or three weeks. In many cases increased purulent discharge followed parathyroid therapy. He believed the action to be a stimulation of leucocytes, probably indirectly through the action of calcium on blood plasma. Broadly speaking, he believed that the use of parathyroids increased physical resistance to bacterial disease.

The President called on Prof. W. E. Dixon to describe recent experimental evidence of the action of ovarian extract.

Prof. Dixon said that Harvey Cushing had observed that pituitary extract was secreted into the cerebrospinal fluid. In order to determine whether pituitary secretion was present in the cerebro-spinal fluid, Prof. Dixon had put a cannula into the spinal canal in dogs and cats and had tested the fluid by its action on uterine muscle. He succeeded in finding pituitary extract present in nearly every specimen, though different samples contained different amounts. In attempting to ascertain what substance or substances could increase the pituitary secretion, he found that the one substance which invariably produced an immediate increase in pituitary secretion was ovarian extract boiled, filtered, and injected into a vein. The active substance was not present in the corpus luteum, nor was orchitic extract efficacious. This stimulating action of ovarian extract appeared to offer an explanation of the normal action of the pituitary body on uterine muscle. It did not explain the intestinal action of pituitary extract. However, it was found that extracts of duodenum also produced increased pituitary secretion, though not immediately. The increase was smaller and more prolonged. Prof. Dixon suggested that the action might have something to do with facilitating absorption in the alimentary canal. Pituitary extract increased the tone of the whole of the small intestine, and wide relaxation of the large intestine was associated with this, the reason being unknown.

The President said that the cold douche of scepticism with which Prof. Vincent had opened the proceedings was refreshing. It was only fair to say that organotherapy was a good deal behind endocrinology. The value of clinical observations was very difficult to assess, but the methods described by Drs. Vines and Grove appeared to indicate one way of making progress. Prof. Dixon's researches had shown that ovarian extracts had some action. It was hardly fair to say that the pharmacological effects of pituitary extract had nothing to do with the effect of the whole gland. The President quoted two cases in which ovarian extracts had appeared to be of some use.

Reply.

Prof. Vincent commented on the fact that throughout the discussion the only extracts claimed as having therapeutic efficacy in which no pharmacological action was discoverable were the parathyroids. He could see no reason why any agent should have a pharmacological effect if it had no physiological action, and therefore he still reserved his opinion on the question of the parathyroids. This was the first time he had heard of any effects of ovarian extract. It was assumed by the President that he had attempted to disparage clinical evidence, but he did not mean to do this, but only to dwell on the necessity of controls and a full record of cases.

ROYAL ACADEMY OF MEDICINE IN IRELAND:

MEDICAL SECTION.

A meeting of this section was held on Jan. 5th, with Dr. T. Gillman Moorhead, the President, in the chair.

Dr. Leonard Abrahamson read a paper entitled

Two Cases of Paroxysmal Tachycardia

illustrated by electro-cardiograms. He pointed out that the term "paroxysmal tachycardia" has been applied to various conditions differing essentially in mechanism. A case of sudden acceleration of the heart rate might belong to one of four groups: (1) Paroxysms of simple or sinus tachycardia; (2) paroxysms of auricular fibrillation; (3) paroxysms of auricular flutter; (4) paroxysms of extra-systoles. Dr. Abrahamson's first case exemplified a paroxysm of extra-systoles. The patient, a female aged 22, who presented a stenosis and regurgitation of the mitral valve, was first seen in the out-patient department of Mercer's Hospital on Monday, July 11th, 1922. She was then suffering from a paroxysm of tachycardia which had commenced abruptly on the previous Sunday. Electro-cardiograms showed a series of extra-systoles, rate 200–205 per minute. The second case demonstrated a paroxysm of auricular fibrillation, rate 170–180, occurring in a male, aged 58, the subject of advanced myocardial disease. The tracings were shown in order to demonstrate the difference between the mechanism of this paroxysm and of the preceding one. After the subsidence of the attack, the patient developed a chronic auricular fibrillation.

The President inclined to retain the general term paroxysmal tachycardia, for often it was difficult in rural cases to make an exact diagnosis. As to treatment, he had recently seen a case in which the patient was immediately able to check the tachycardia by pressing deeply on each side of his neck.—Dr. H. F. Moore preferred to retain the term paroxysmal tachycardia provided that it was only employed in a clinical sense. He was of opinion that nurses should be taught to use the stethoscope to count heart beats.

The President read a short paper on

Milk Anaphylaxis,

using the term to signify a special sensitiveness on the part of some patients to milk. He protested against the almost universal and indiscriminate use of milk in cases of gastric disorder, and pointed out that in many cases the use of this fluid merely aggravated the condition that it was intended to cure. He reported a case in which, after two operations had been performed and nothing wrong being found, relief was immediately obtained by stopping all milk food. During the progress of the case on one or two occasions milk was given accidentally, and was each time followed by the occurrence of acute gastric pain and vomiting.

Sir John Moore agreed with the President that milk sometimes was one of the worst things which could be given to patients; whey and egg water, raw meat juice, and port wine were good substitutes.—Dr. ABRAHAMSON described a case of mucous colitis cured by forbidding milk.—Dr. T. P. C. KIRKPATRICK said that Dr. Hastings Tweedy had regarded milk as the worst form of food which could be given to a patient suffering from eclampsia. Milk was a satisfactory diet only for patients who liked it.—Dr. G. E. NESBITT asked whether the President had any faith in the skin tests which had lately been largely used.—Dr. T. J. D. LANE said it was important to find out whether when milk disagreed this was due to anaphylaxis or not. If the patient gave an anaphylactic response to ordinary milk and not to boiled milk, that was a point in favour of anaphylaxis.—Dr. MOORE said he believed excellent results had been obtained by means of skin tests.—Dr. KENNEDY CAHILL gave details of numbers of cases in which a milk diet had proved harmful.—Dr. R. J. ROWLETTE had also had experience of cases in which milk appeared to increase the disorder.—Dr. C. PILE suggested that the substitution of hot water for milk diet in cases of catarrhal jaundice might cause cases to clear up more quickly.

Dr. NESBITT read notes on

Renal Efficiency Tests.

He demonstrated three tests which he had found most serviceable—viz., the urea-concentration test, the estimation of blood-urea, and the excretion of phenolsulphone-phthalein. He had followed for the most part the methods and technique recommended by Prof. H. Maclean and had found them very satisfactory. He had made some minor alterations in the estimation of blood-urea which he thought were advantageous—one was the addition of a side tube by means of which alcohol could be added at any time to control frothing, and another was the immersion of the blood tube in a jacket of warm water during distillation, which brought over the ammonia more thoroughly and quickly. As regards the value of the tests, he thought no just opinion could be expressed in a doubtful case of nephritis based on clinical findings alone, nor should serious genito-urinary surgery be undertaken till the condition of the kidneys had been ascertained by some such means as these. Not the least value of the tests was the possibility of demonstrating sound renal function in cases which had been rejected for life insurance, or been treated as chronic invalids on account of the presence of albumin and even casts in the urine. He thought the urea-concentration test the most reliable. High blood-urea in chronic cases was of serious prognosis, but a low figure was not necessarily favourable. The phenol-phthalein test should always be used in conjunction with other tests, or it might mislead.

Dr. MOORE said that these tests were valuable when carried out in conjunction with the ordinary physical examination of patients.—Dr. V. M. SYNGE said that he had found the curve of water excretion a very simple and reliable guide in these cases.—Mr. C. E. BRUNTON said he had carried out a critical examination of the blood-urea estimation in conjunction with Dr. Fearon with a view to the discovery of fallacies, and they had discovered quite a number. He was much interested in the steps taken by Dr. Nesbitt to counteract some of these. He thought the use of the warm water jacket was an important addition to the technique.

LIVERPOOL MEDICAL INSTITUTION.

A MEETING was held on Jan. 4th, with Prof. J. HILL ABRAM, the President, in the chair.

Mr. R. C. DUN read a note on

Chronic Intussusception in Children.

Mr. Dun referred to ten cases. All were operated on and recovered. In no case was there any difficulty in reduction and no adhesions were found. The average age of the children affected was 5 years. The duration of symptoms was from four weeks to two and a half years. An abdominal tumour was felt in six out of the ten cases. Blood and mucus was passed per rectum in only two of the cases, and in no case was complete obstruction reached. In none of the cases was any definite pathological condition found which would account for the formation of the intussusception.

Mr. J. T. MORRISON said there were cases with border-line symptoms between the acute and chronic types. One case, a boy, aged 18 months, having previously had a typical ileo-cæcal acute intussusception, was again seized with a similar attack. Operation showed a pure colic intussusception easily reducible and without œdema or congestion. Another case, a boy, aged 5 years, had symptoms of acute obstruction of a definite but not very severe type necessitating immediate operation. There was no blood or mucus, but a vague tumour in the right side of the abdomen. Previous health had been excellent. At operation a very easily reducible intussusception of the ileo-cæcal type was found. There was practically no œdema of the apex. During convalescence he had an attack of fever (104° F.), blood and mucus in the stools, of one day's duration. Otherwise there were no further symptoms. Was this an abortive attack of intussusception or was this merely an attack of enteritis?

Dr. A. DOUGLAS BIGLAND read a note on the

Diagnosis and Treatment of Migraine.

He pointed out that only one event of the migraine attack might be the sole feature, and that therefore diagnosis was not always easy. He described cases and advocated treatment by calcium salts.

Dr. T. W. WADSWORTH described a case of

Syphilis of the Lung

in a patient, aged 17, who complained of cough and slight expectoration for six months. She was poorly nourished, fingers clubbed, incisor teeth notched, Wassermann reaction positive, sputum negative as regards tubercle bacilli. There was an area of dullness just below the inferior angle of the left scapula. The breath sounds were bronchial in this area and there was pectoriloquy and crepitations. X ray of the chest showed a shadow corresponding to the area found clinically. After treatment with iodides and mercury and an injection of 0·3 g. N.A.B. the physical signs cleared up and the X ray of the chest demonstrated that the opaque area had almost vanished. From the evidences of syphilis, the absence of tubercle bacilli, and the response to treatment the diagnosis was established.

Mr. H. HAWARD BYWATER read a paper on

Night-Blindness.

Mr. Bywater divided the condition into two groups: (1) the congenital and hereditary forms; (2) the acquired varieties. The first group comprised the rare congenital form with normal fundi, which was stationary, and the three hereditary conditions: (*a*) retinitis pigmentosa (and its non-pigmentary form); (*b*) retinitis punctata albescens; (*c*) gyrate atrophy of the retina and choroid, which were progressive. The second group comprised: (*a*) acquired retino-choroiditis as syphilitic (which becomes stationary if treated); (*b*) epidemic night-blindness (this, the most important form, might or might not be associated with xerosis of the conjunctiva); (*c*) physiologic night-blindness of the one-eyed, described by Thomson Henderson. After giving reasons why myopes and hypermetropes had difficulty in seeing at night, Mr. Bywater gave particulars of 70 cases of night-blindness seen in Salonika by Major Usher and himself in 1917, with the tests applied. He mentioned that 14 out of 70 were men who had only useful vision in one eye. The cases of the epidemic form of night-blindness occurred in miners during the last coal strike, and of xerosis in children. After briefly discussing the theories of night-blindness, he described the experiments to prove that visual purple formation is carried out by the eye itself independent of the central nervous system. The changes in the visual purple appeared to be due partly to ultra-violet rays of greater length than 300 microns and partly by rays of the visual spectrum. Experiments to show the protection given by the media of the eye against the harmful rays of bright light were mentioned, and, finally, the diagnosis and treatment of the different varieties.

Dr. A. E. BURROUGHS considered the most interesting aspect of night-blindness to be the congenital stationary type, that in which night-blindness exists along with no other apparent abnormality of the eyes. This was purely hereditary and occurred in families, often through many generations. A full account, giving extensive family trees of affected families, had just been issued from the Eugenics Laboratory of Prof. Karl Pearson. A type had appeared in which the female members of a family escaped, but passed it on to the males. The affection was supposed to be rare, and in its higher degrees it no doubt was so, but he had come across many cases of modified congenital stationary night-blindness, especially noticeable at the time of the lighting restrictions during the war.

Reviews and Notices of Books.

STUDIES IN PSYCHO-ANALYSIS.

By CHARLES BAUDOUIN, Author of "Suggestion and Auto-suggestion." Translated from the French by E. and C. PAUL. London: George Allen and Unwin. 1922. Pp. 351. 12*s.* 6*d.*

Prof. Baudouin describes a combination of suggestion with psycho-analysis, and although he narrows the latter term to mean a method and not a body of doctrine, yet his method differs in essentials from that recognised as psycho-analysis. The use of suggestion to overcome resistances, for example, was abandoned by Freud when he perfected his method of free association, for he considered that the overcoming of resistances by the patient's own efforts was, in fact, of more importance than the revival of memories. The statement that the form taken by the transference—i.e., the affective relationship of subject to operator—is involuntarily imposed by suggestion from the analyst embodies a fundamental difference in observation. "If we invite the subject to expect its appearance in a certain form, and if we ourselves expect it to appear in this form, the odds are that, thanks to the working of suggestion, the expected will happen" (p. 114), is a sentence that might even lead us to misjudge the author's knowledge of his subject, for it is the kind of thing one hears from critics whose acquaintance with psycho-analysis rests upon hearsay. Nevertheless, the relation of suggestion to transference is admitted, though here again a vital difference of viewpoint is manifest; the aim of analysis is to free the patient from his own inhibitions and from the temporary dependence upon the analyst; but the author quotes approvingly (p. 116) a comparison of psycho-analysis to the spiritual directorship of the confessional, a comparison especially misleading to any reader who tends to confuse confession with the analysis of the unconscious. These faults are to be regretted.

One aim of the book is to introduce psycho-analytical theories to French readers, most of whom, says Prof. Baudouin, are beginners, but even if his views are sound they should not be presented under the guise of psycho-analysis. The combination of analysis and suggestion is justified by the length and expense of analytical treatment, and the author describes, among others, the case of a patient suffering from timidity and undue scrupulosity who was rapidly cured by a combined method. We have to thank workers like Prof. Baudouin for simplifying and placing at our service whatever of curative value there is in suggestion, but he does not show whether, or how, suggestion differs from the methods of healing by faith that have hitherto, with more or less success, mocked at orthodox medicine. The "law of subconscious teleology"—"When the end has been suggested, the subconscious finds means for its realisation," only means that the process is not accompanied by awareness, and its unsatisfying nature is not lessened by the naïve remark that "The subject may be entirely ignorant of physiology and may remain quite unaware of what is going on within him" (p. 110).

The exposition of theory contains a useful chapter tracing the relation between modern views of affective association and the older ones that based association upon the laws of contiguity, similarity, and contrast, but it leaves us wondering what psycho-analysis is and what is its relation to treatment. The cases described later are equally inconclusive, that of "Alfred," for instance, being merely an example of the "analyst" explaining to the patient what he thought was the motive of his stammer. The translators are over-enthusiastic when they prophesy: (p. 12) "The student will return with delight to the clarity of what is destined to become known as the Geneva School, and will read the Studies again and again." But this volume will interest many people who are seeking to find connexions between opposite schools of thought in psychotherapy.

PRACTICAL PHYSIOLOGY.

By E. P. CATHCART, M.D., D.Sc., F.R.S., Gardiner Professor of Chemical Physiology, University of Glasgow; D. NOËL PATON, M.D., LL.D., F.R.S., Regius Professor of Physiology, University of Glasgow; and M. S. PEMBREY, M.A., M.D., F.R.S., Professor of Physiology, Guy's Hospital, University of London. London: Edward Arnold and Co. 1922. Pp. 344. 18*s.*

THIS book is based on a work, now out of print, by A. P. Beddard, J. S. Edkins, M. Flack, L. Hill, J. J. R. Macleod, and M. S. Pembrey. These six authors were all at the time teaching physiology in London medical schools, but in the present edition the centre of gravity has shifted to Glasgow, except for the section on advanced experimental physiology, by Prof. Pembrey. A result of this compromise may be that the courses outlined will not be wholly acceptable at either school, or at any other, though no doubt a little adaptation would fit them for most medical schools. The most difficult of the courses to adapt would be that on Elementary Experimental Physiology, for this begins with observations on the special senses, where most courses end, and further, some of the apparatus described, the electric supply for instance, is not to be found in most laboratories. The exercises chosen in the various courses are of the kind given in most medical schools, and questions relating to them are set at most examinations. Courses of mammalian or human physiology are only very partially realisable in practice, and although the authors say in the preface that "practical work should have a direct relation to medicine and, as far as possible, the experiments should be performed upon man," the subsequent text demonstrates the impossibility of this being properly done.

Although on the whole the instructions for the performance of experiments are clear enough, instances of ambiguous writing are not hard to find: thus p. 169, "Take the temperature of a mouse in the rectum and then place it in a dry thermostat"; p. 170, "If the animal be now laid on a table with its limbs spread out"; or p. 146, "In comparing the tints hold the tubes against the skylight." As students often take things very literally, such loose wording is dangerous. In the chemical section, it should be pointed out that the illustrations of crystals are far too large—a figure of a hæmin crystal half an inch in length would puzzle students enormously. In dealing with the determination of the oxygen capacity of blood, the use of the new Haldane or Barcroft apparatus could have been described just as easily as the method requiring 20 c.cm. of blood.

These represent the only faults we have to find with the book; in its favour we can say that it does really present a course of work which is possible in most schools, that the instructions and the theoretical parts are adequate, and that the exercises chosen show good balance, as little stress as possible being laid on merely academic experiments on frog's legs, apart from classical experiments which illustrate fundamental truths.

TROPICAL DISEASES.

Fourth edition. By E. R. STITT, Rear-Admiral, Medical Corps. and Surgeon-General, U.S. Navy. London: H. K. Lewis and Co., Ltd. 1922. Pp. 622. 18*s*.

THE first edition of this useful and handy little manual appeared only eight years ago; since that time three other editions have appeared, testifying to the deserved popularity of the book. In this edition yellow fever has been definitely included amongst the protozoal diseases, and a full account of the *Leptospira icteroides* and the more recent advances in the pathology and treatment based upon Noguchi's work have been well set out. Epidemic jaundice and rat-bite fever are more briefly treated. In the account of plague we miss mention of the recent work of L. F. Hirst and F. W. Cragg on *Xenopsylla astia*, possibly because its significance has only recently been recognised. An account of tularæmia, a mysterious but extremely obnoxious plague-like fever, is given; this is primarily a disease of rodents, caused by an organism, *Bacterium tularense* (discovered by McCoy and Chapin in 1911), but which is transmitted to man by a horse-fly, *Chrysops discalis*, previously having imbibed the blood of infected jack-rabbits. As a result of accidental infection it seems that almost 100 per cent. of those engaged in investigating tularæmia themselves contract it.

The sections on pellagra and beri-beri have been revised in accordance with recent advances. In Chapter XXV. are included tables of important animal parasite diseases, protozoal, helminthic, and arthropodan. One of the defects of this little book is the unsatisfactory nature of some of the illustrations; even when objects have to be reproduced on a small scale, some indication should be given of the actual magnification, or the student can obtain no idea of the relative size of objects. An example of this need is illustrated in Figs. 119 and 120, where the embryo *Strongyloides intestinalis* in the latter, which is 0·2 mm. in length, is depicted twice the size of *Fasciolopsis buski*, in reality 30 mm. In Figs. 30 and 31 the legends have become transposed. The broad outlook of the author is nowhere better illustrated than in the section devoted to diagnostic problems and procedures, together with a consideration of cosmopolitan diseases in the tropics; the tropical practitioner is reminded that in addition to his knowledge of parasitology he must be familiar with the principles and practice of general medicine.

X-RAY TECHNIC FOR DIAGNOSIS.

Principles and Practice. By JOHN A. METZGER, M.D., Roentgenologist to the School for Graduates of Medicine, Medical Department, University of California, Los Angeles. London: Henry Kimpton. 1922. Pp. 144. 14*s*.

THE author's aim in the preparation of this book is to put into the hands of the student and operator a formula on which to base his work in order that he may obtain better results and thus be able to reach a more correct diagnostic interpretation. The table of exposures given is not meant to be followed as a fixed rule, but the exposures are those which have given the author the best results. Dr. Metzger is certainly successful in helping the beginner to get an idea of the detailed technique of radiophotography and a sound basis on which to start practical work. As in many volumes of limited scope, the selection of matter to be included has obviously been a difficulty. The glossary of terms at the beginning of the book might well be left out of a later edition, because such definitions as "Atom—an ultimate indivisible particle of matter," or "Current Controller—a device or rheostat for controlling current," or, again, "Erg—the unit of work," are of little value. The description of the Bucky diaphragm is incomplete, as it gives no details of the structure of the diaphragm while attempting to explain how it works. Work with the fluorescent screen is described in less detail than the taking of photographic plates. The photographs of the positions in which the patient is placed for regional examinations are excellent, and the section on development is helpful. The differences of nomenclature used in America have produced words that look clumsy to British readers, such as roentgenogram, pyeloroentgenography, kinematography, or bioroentgenography, and roentgenologist; radiologist and skiagram are rarely employed. The expression "plating" is here used for taking an X-ray photograph; this is unfortunate, since "plating" has a definite surgical meaning, and words which already have a technical significance should not lightly be used in another sense.

The book as a whole is a sound and useful guide to the technique of radio-diagnosis.

ANATOMY.

Cunningham's Text-Book of Anatomy. Fifth edition. Edited by ARTHUR ROBINSON, M.D., F.R.C.S. Edin. London: Henry Frowde and Hodder and Stoughton. 1922. Pp. 1577. 42*s*.

THE new issue of this standard work shows certain changes in the names of those responsible for the sections and in the detail of its contents. Dr. E. B. Jamieson has taken up the osteological revision which Prof. A. Thomson was unable to execute, Profs. Whitnall and Johnston have revised the portions originally written by the late Prof. Paterson, and Prof. J. T. Wilson, of Cambridge, has entirely rewritten and enlarged the scope of the section dealing with ductless glands. The names of the contributors, the able editorship of Prof. Robinson, and the reputation of "big Cunningham" are sufficient guarantees of the excellence of the book, which has become established as one of the best of its kind, as it has always been. It is wonderfully free from slips. A mistake in labelling in Fig. 196, bearing on the attachments of tendons by the bicipital groove, will bear correction.

Altogether an admirable production.

Practical Anatomy. Second edition. By R. J. A. BERRY, M.D. Edin. & Melb., F.R.S.E., F.R.C.S. Edin., Professor of Anatomy in the University of Melbourne. London: H. K. Lewis and Co., Ltd.; Melbourne: Robertson and Mullen's, Ltd. 1922. In four volumes.

THE first edition of this work met with considerable success in Australia and elsewhere, and Prof. Berry has taken advantage of the early demand for another issue to revise and alter in many ways the original production. His object has been to produce an "anatomy of the living" rather than of the dead, and to direct the mind of the inquiring student towards paths of proved clinical worth rather than to allow him to abide in the fields of pure anatomy. This is an ideal which many have set up before them, but we cannot at the moment recall the names of any who were conspicuously successful in their efforts to reach it. Nor is it hard to see the reason for this; the structure or connexion which may seem to one writer of merely anatomical interest may, in the mind of another, have a definite clinical or pathological value, or some small experience at the bedside may lead one man to see the worth of a piece of anatomical information, although the vision may be entirely denied to another—possibly because he is lacking in such information. As an example of the first of these possibilities we may point to the fact that the author of this work does not seem to consider a description of the details of the arterial arrangements of the intestine to be of clinical importance, which is not the opinion, we imagine, of Latarjet and many others; parallel instances can be found in large number in every book that essays to draw the line between the essential and non-essential in anatomical matters. So far as the anatomical part of the work is concerned, and its value to the anatomical student, the mere fact that a second edition has been so soon called for is enough in itself to show that Prof. Berry has expended his great labour to good purpose. We confess that we do not share his great admiration for Ellis's plates, when reduced and removed from their surroundings. We cannot help feeling that clear diagrams and schemes are more helpful to a student who wishes to see how a structure gets there, than the most artistic production, when there is always available the actual material for reference. A few diagrams showing the courses of tracts would add to the value of the excellent volume dealing with the central nervous system. The printing is clear and good, and the work is well got up, and altogether, though we may consider Prof. Berry's ideal impossible of achievement, we congratulate him on the appearance and general scheme of the second edition of his work.

A Manual of Surgical Anatomy. Second edition. By LEWIS BEESLY, F.R.C.S. Edin., and T. B. JOHNSTON, M.B., Ch.B. London: Henry Frowde and Hodder and Stoughton. 1922. Pp. 561. 18*s.*

THIS is an excellent little book, which will well repay study by practitioners and senior students. The importance of the subject will, we hope, lead in future editions to more extended treatment of the lumbrical-space connexions with Kanavel's fascial spaces in the hand. We disagree with the authors in what appears to be their view of the axes of movement in the jaw-joint, and in one or two other minor matters, but this does not lessen our appreciation of the work which, in most respects, could hardly be improved upon.

Topographisch-anatomische Sezierübungen. By Dr. FRANZ KISS, Prosektor am anatomischen Institut der Universität Ofenpest. Lehmanns Medizinische Lehrbücher. München: J. F. Lehmann. 1922. Pp. 83. 10*s.*

THIS little book is intended for the use of those who wish to run over the topographical points after they have acquired a fundamental acquaintance with the body at large. The brain and the visceral contents of the thorax and abdomen do not come within the scope of the work. Each region is defined and then described in the general order of dissection, and the descriptions are good and reliable. The illustrations are at first sight somewhat startling in their colour schemes, but this can be supported on certain grounds. We would, however, recommend more careful inspection of the labels attached to exposed structures in some of the figures, and we have detected one or two textual misprints. The book appears to serve its purpose very well.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

The Records of the Aberdeen Medico-Chirurgical Society, 1789–1922. By JOHN SCOTT RIDDELL, President of the Society. Aberdeen: W. and W. Lindsay. 1922. Pp. 144. 4*s.* 6*d.*

THIS interesting book is an expansion of the annual address delivered before the Aberdeen Medico-Chirurgical Society in 1922. In his introduction Mr. Riddell gives us an amusing account of his struggles, as the fatal day of delivery approached, to find a subject. His first idea, that of giving a sketch of an old-fashioned country practitioner, he rejected as not being dull enough for a presidential address; draft No. 2 entitled "Sign Posts and Milestones" was rejected as being too dull. Then a happy thought struck him—to call his address "A Hundred Years After" and take for his text the presidential address of 1822. Careful search of the Minutes for 1822 revealed that there was no presidential address in 1822, neither for many years before and after that date. Determined not to be beaten, Mr. Riddell went back to the very early days of the Society and found that every one was president in turn, a presidential address was delivered at every meeting, and there was a meeting once a week. It is pleasing to note that the Minutes of the meeting of Oct. 15th, 1790, say, "We then proceeded to the Tavern, where we spent the greater part of the Meeting in Mirth and Jollity." So Mr. Riddell decided to write a compendium of the sayings and doings of the Society and to give such historical incidents as he deemed would be amusing, gathered from the stores of knowledge which he had acquired from delving into its records. And a very interesting book he has made of it.

This ancient medical society was founded as the Aberdeen Medical Society by James McGrigor and sundry others in 1789 "on a basis of self and mutual help and was pervaded by a spirit of great earnestness and high endeavour." James McGrigor was in later life Wellington's chief medical officer in the Peninsula, receiving a knighthood for his services, and from 1815 to 1851 Director-General of the Army Medical Department. The minutes of the early days of the Society's activities contain various references to the procuring of subjects for dissection, and it is characteristic of the sportsmanship of Aberdeen students that they took the whole risk of robbing the graves themselves and did not depend upon professional resurrection men. The varying fortunes of the Society and its relation with the two universities, King's College and Marischal College (they were united in 1860 as the University of Aberdeen), are well described—indeed, the whole book is worth reading. We may note one item of special interest to ourselves—namely, that the *Aberdeen Lancet*, founded in 1831, was brought into being by "a Society of Young Gentlemen, who had observed the benefit to the Medical Profession of the operation of the London *Lancet*." Mr. Riddell's quotations suggest that the northern journal was in no way inferior in vigour to its London predecessor.

FLAVOURING MATERIALS.

Natural and Synthetic. By A. CLARKE, F.C.S. Oxford Technical Publications. London: Henry Frowde and Hodder and Stoughton. 1922. Pp. 166. 8*s.* 6*d.*

THIS is an interesting little book dealing with spices, condiments, and flavouring bodies, with the preparation and analysis of essential oils, with perfumes, and with odorous chemical products generally. Many interesting fields of research are indicated in notes which are for the most part arranged under alphabetical headings, while the introduction contains a useful bibliography for readers who wish to study recent progess in the classification of perfumes and the correlation of odour with chemical constitution. The author is right, from the medical point of view, to dwell upon the importance of flavouring compounds in the assimilation of foodstuffs, for the digestion of food is greatly increased by its palatability. Many who are doing a full day's work find their relish for food at the end of the day has waned, and at the very time when their largest meal is placed before them. A little ingenious experimentation with flavouring agents may work wonders here, as it does with the small appetite of the convalescent. Some useful hints are given in various places upon adulterants, and it may come as a surprise to some readers to learn how numerous are the substances which are used as partial substitutes of spices and condiments. The same baneful practices appear to exist in the preparation of essential oils, where the chief methods of sophistication are numerous.

The book summarises in a brief and readable fashion a great deal of information of real value.

Edward Jenner.

BORN MAY 17TH, 1749—DIED JAN. 26TH, 1823.

Edward Jenner, who was born on May 17th, 1749, at Berkeley in Gloucestershire, died on Jan. 26th, 1823, in his house at that same village, where he spent the greater part of his life, and where in 1796 he performed the first vaccination. We print below the first and hitherto unpublished summary of his own observations on his work, as contained in the holograph manuscript in the library of the Royal College of Surgeons of England. The manuscript consists of 45 quarto pages, the numbers of which we indicate in brackets in the text. We have deleted certain references to an illustration and to what was apparently a case-book, neither of which are now available. On a blank page at the beginning is a note, also in Jenner's own hand, which reads: "On the Cow Pox. The original paper." Certain emendations in the text suggest that he intended to send the paper to some society, but no evidence exists to show that it was ever sent. In June, 1798, Jenner published an amplification of his observations; this classic treatise was entitled "An Enquiry into the Causes and Effects of the Variolæ Vaccinæ, a Disease discovered in some of the Western Counties of England, particularly Gloucestershire, and known by the name of the Cow Pox." This book, "printed for the author by Sampson Low, No. 7, Berwick-street, Soho, and sold by Law, Ave-Maria-lane; and Murray and Highley, Fleet-street," is a quarto of 75 pages, dedicated to Dr. C. H. Parry of Bath. It contains coloured plates, one of which shows the hand of Sarah Nelmes with vaccine pustules upon it. We are indebted to the Curator of the Wellcome Historical Medical Museum for permission to reproduce the illustrations which accompany the article.

AN INQUIRY INTO THE NATURAL HISTORY OF A DISEASE KNOWN IN GLOSTERSHIRE BY THE NAME OF THE COW-POX

[1] The deviations of Man from the state in which he was originally plac'd by Nature seem to have proved to him a prolific source of Diseases. From the love of splendor, from the indulgences of Luxury, & from his fondness for amusement, he has familiariz'd himself with a great number of animals which may not originally have been intended for his associates. The Wolf,[1] disarm'd of ferocity, is now pillow'd in the Lady's lap. The Cat, the little Tyger of [2] our Island, whose natural home is the Forest, is equally domesticated & caress'd. The Cow, the Hog, the Sheep & the Horse, are all for a variety of purposes brought under his care & dominion.

There is a disease, to which the Horse, from his state of domestication, is frequently subject. The Farriers have termed it *the Grease.* It is an inflammation & swelling in the heel, from which issues matter possessing properties of a very peculiar kind. It is capable of generating a Disease in the human body (after it has undergone the modification which I shall presently speak of) which bears so strong a resemblance to the smallpox, that I think it highly probable it may be the source of that Disease. [3] In this dairy Country, a great number of Cows are kept.

The office of milking is here perform'd, indiscriminately, both by Men & Maid Servants. One of the former having perhaps been appointed to apply dressings to the heels of a Horse affected with *the Grease*, and not paying due attention to cleanliness, incautiously bears his part in milking the Cows, with some particles of the infectious matter adhering to his fingers. When this is the case it commonly happens that a disease is communicated to the Cows, &, from the Cows, to the Dairy Maids, which pretty rapidly spreads until most of the Cattle and domesticks of the Farm feel its unpleasant consequences. It first appears on the Nipples of the Cows in the form of irregular Pustules. They are seldom white, but more commonly of a palish blue, or rather of a colour somewhat approaching to livid, & are generally surrounded by an erysipelatous Inflammation, & [4] These Pustules, unless a timely remedy be applied are much disposd to degenerate into phagedenic ulcers which prove extremely troublesome.[2] The Animals become indispos'd and the secretion of Milk is much lessend. Several inflam'd spots appear on different parts of the hands [5] of the Domestics employ'd in milking, and sometimes on the Wrists, which quickly run on to suppuration first assuming the appearance of the small vesications produc'd by a burn. Most commonly [6] they appear on the joints of the fingers; but whatever parts are affected, if the situation will admit, these superficial suppurations put on a circular form, with their edges more elevated than their centre, and of a colour distantly approaching to blue. Absorption takes place, and Tumors appear in each Axilla—the System becomes affected—the pulse is much quickend, and shiverings with general lassitude & pains about the loins & limbs, with vomiting, come on. The Head is painful, and the patient is now & then even affected with Delirium. These symptoms, varying in their degrees of violence (for they rarely attack so severely) generally continue from one day to three or four, leaving ulcerated sores about the hands, which, from the sensibility of the parts, are very troublesome, [7] frequently becoming phagedenic like those from whence they sprang, and commonly heal slowly. The Lips, Nostrils, Eyelids, and other parts of the body are sometimes affected with sores; but these arise from their being heedlessly rubb'd or scratch'd with the Patient's infected Fingers. No eruptions of the skin have follow'd the decline of the feverish symptoms in any instance that has come under my inspection, one only excepted, & in this a very few only appear'd on the arms. They were of a vivid red colour, very minute and soon died away without advancing to maturation: so that I cannot determine whether they had any connection with the preceding symptoms, but am induc'd to think they had not.

Thus the disease makes its progress from the Horse to the Nipple of the Cow, & from the Cow to the human subject.

[8] Morbid matter of various kinds, when absorb'd into the System, may produce effects in some degree similar; but what renders the cow-pox virus so extremely singular, is, that the Person, who has been thus affected, is for ever after secure from the infection of the small-pox; neither exposure to the variolous effluvia, nor the insertion of the matter into the skin producing this malady. In support of this assertion I shall produce many instances. I *could* produce a great number more; but, the following I presume will be fully sufficient to establish the fact very satisfactorily.

[9] Case 1st.

Joseph Merret, now an under Gardener to the Earl of Berkeley, lived as a Servant with a Farmer near this place in the year 1770 and occasionally assisted in milking his masters Cows. Several Horses, belonging to the Farm, began to have sore heels, which Merret frequently attended. The Cows soon became affected with the Cowpox ; &, presently after, several sores began to appear upon his hands. Swellings and stiffness in each Axilla follow'd and he was so much indispos'd for several days, as to be incapable of pursuing his ordinary employment.

---

[1] The late Mr. John Hunter proved by experiments that the Dog is the Wolf in a degenerated state.

[2] They who attend sick Cattle in this Country find a speedy remedy for stopping the progress of this complaint, in those applications which act chemically upon the morbid matter, such as solutions of the Vitriolum Zinci, the Vitriolum Cupri, etc.

It is of importance to remark that there are other causes besides contagious matter which produce Pustules & sometimes ulcerations on the Nipples of Cows; and instances have occurr'd, of the hands of the Servants employ'd in milking being affected with sores in consequence, and even of their feeling an indisposition from absorption. But these instances are very rare. This Complaint appears at various seasons of the year, but most commonly in the spring, when the Cows are first taken from their winter food and fed with grass. It is very apt to appear also when they are suckling their young.—But this disease is not to be consider'd as having any kind of connection with that of which I am treating, as it is incapable of producing any specific effects on the human constitution. This distinction between the two Diseases becomes the more important, as the want of it might occasion an idea of security from the infection of the smallpox which would prove delusive.

In April 1795, a general inoculation taking place here, he was inoculated with his family ; so that a period of twenty five years had elaps'd from his having the Cow-pox to this time. However, tho' the [10] variolous matter was repeatedly inserted into his arm, he could not be infected with it ; an efflorescence only, taking on an erysipelatous look about the centre, appearing on the skin near the punctur'd parts. During the whole time that his family had the smallpox, one of whom had it very full, he remained in the house with them, but received no injury from exposure to the contagion.

It may be necessary to observe, it was clearly ascertained previous to this attempt to produce the disease, that neither this Patient, or any other whose case is here represented, ever had the smallpox.

[11] Case 2nd.

Sarah Portlock of this place was infected with the Cowpox, when a servant at a farmers in the neighbourhood, twenty seven years ago. In the year 1792 conceiving herself from this circumstance secure from the infection of the smallpox, she nurs'd one of her own children who had accidentally caught the disease, but no indisposition ensued in consequence. During the time she remaind in the infected room, variolous matter was inserted into both her arms, but without any further effect than in the preceding case.

Case 3rd.

John Phillips a Tradesman of this Town had the Cowpox at so early a period as nine years of age. At the age of 62 [12] I inoculated him, and was very careful in selecting matter in its most active state.[3] It was taken from the arm of a Boy just [13] before the commencement of the eruptive Fever and instantly inserted. It very speedily produc'd a sting-like feel in the [14] part. An efflorescence appeard, which, on the 4th day, was rather extensive, and some degree of pain & stiffness were felt about the shoulder ; but, on the 5th day, these [15] symptoms began to disappear, and, in a day or two after, went entirely off without producing any effect on the System.

Edward Jenner, from an engraving by W. Read (at the Wellcome Historical Medical Museum).

[16] Mary Barge, of Woodford, in this Parish, was inoculated with variolous matter in the year 1791. An efflorescence of a palish red colour soon appeard about the parts where the matter was inserted, and spread itself rather extensively, but died away in a few days without producing any variolous symptoms.[4]

She has since been repeatedly employ'd as a Nurse to smallpox Patients, without experiencing any ill consequences. This Woman had the Cow-pox when she lived in the service of a Farmer 31 years before.

[17] Case 4th.

I believe it to be very rare for one Individual accidentally to communicate the cowpox to another. My Notes furnish me with one instance only. Mrs. H. a respectable Gentlewoman of this Town, had the Disease when very young. Her hands were extremely sore, & her Nose was inflamd and very much swoln. It was communicated by some of the servants of the Family (who were infected by Cows) and certainly by contact, [18] probably by her handling some of the same family utensils. Soon after this event, Mrs. H was expos'd to the contagion of the smallpox, where it was scarcely possible for her to have escaped it, as she regularly attended a Relative who had the disease in so violent a degree that it proved fatal to him.

In the year 1778, the smallpox prevailing very much at Berkeley, and Mrs H. not feeling perfectly satisfied respecting her safety, no indisposition having followed her exposure to the smallpox, I inoculated her with active variolous matter. The same appearance follow'd as in the preceding Cases ; an efflorescence on the arm, without any effect on the Constitution.

[19] Case 5th.

It is a fact so well known among our Dairy Farmers, that those, who have had the smallPox, either escape the Cowpox, or are disposd to have it slightly, that as soon as the Complaint shews itself among the Cattle, assistants are procured, if possible, who are in that situation, otherwise the business of the Farm could scarcely go forward.

In the Month of May 1796 the Cow-pox broke out at Mr. Baker's a farmer who lives near this place. The disease was communicated by means of a Cow which was purchas'd in an infected state at a neighbouring Fair, and not one of the Farmers Cows consisting of thirty, which was at that time milkd, escaped the contagion. The family consisted of a Man servant, two Dairy Maids & a servant Boy : who, with the Farmer himself, were twice a day employ'd in milking the Cattle. The whole of this [20] family except Sarah Wynne one of the Dairy Maids had gone thro' the smallPox. The consequence was, that the Farmer and the servant Boy escaped the infection of the Cow-pox entirely, and the servt. Man and one of the Maids had each of them nothing more than a sore on one of their fingers, which did not produce the least disorder in the system. But the other dairy Maid, Sarah Wynne, who never had the smallpox, did not escape in this easy manner. She caught the Complaint from the Cows & was effected with it in so violent a degree that she was incapable of doing any work for the space of ten days.

March 28th, 1797 I inoculated this Girl by carefully rubbing variolous matter into two slight incisions made upon the left arm. A little inflammation appeard in the usual manner around the parts where the matter was inserted, but so early as the 5th day it vanished entirely, without producing any effect on the system.

---

[3] I have often been a witness to very direful effects arising from the improper management of the variolous matter, previous to its being used for the purpose of inoculation. A medical Gentleman (now no more) who inoculated great numbers in this neighbourhood, frequently preserved his matter on a piece of Lint or Cotton, which, in its wet state, was put into a Vial, corked up, & convey'd into a warm Pocket, a situation certainly favorable for producing putrefaction in it. In this state (not unfrequently after it had been taken several days from the pustules) it was inserted into the arms of his Patients, and brought on inflammation in the incised parts, swellings of the Axillary Glands, fever, and (as I have been inform'd by the Patients themselves) eruptions. But what was this disease ? Certainly not the smallpox : for, the matter, having from putrefaction lost its specific properties, was no longer capable of producing that malady ; they, who had been inoculated in this manner, were as much subject to the contagion of the smallpox, as if they had never been under the influence of this artificial disease ; and many, unfortunately, fell Victims to it, who thought themselves in perfect security. The same unfortunate circumstance of giving a disease, suppos'd to be the smallpox, with inefficaceous variolous matter, having occurr'd under the direction of some other Practitioners and probably from the same cause, incautious manner of securing the variolous matter, I avail myself of this opportunity of mentioning what I conceive as of great importance, and, as a further cautionary hint, I shall take the liberty of adding another observation on the subject of inoculation.

Whether it be yet ascertain'd by experiment that the quantity of variolous matter, inserted into the skin, makes any difference with respect to the subsequent violence of the disease I know not ; but, I have the strongest reason for supposing that if either the Punctures or incisions be made so deep as to go through it, and wound the adipose covering beneath, that the risk of bringing on a violent disease is greatly increasd.

I have known an Inoculator, whose practice was to go deep enough (to use his own expression) "to see a bit of fat," & there to lodge the matter. The great number of bad Cases & the fatality which attended this practice was almost inconceivable ; and I cannot account for it on any other principle than that of the matter being plac'd in this situation instead of the skin ; for let it be recollected, that it is only a different mode of receiving the infectious particles that constitutes the difference between Inoculation and the natural smallpox. Tho it is very improbable that anyone would inoculate in this way by design, yet this observation may tend to place a double guard over the lancet when Infants fall under the care of the Inoculator, as the skin is comparatively so very thin. Query—In what manner is the smallPox communicated in what is call'd the natural way ?

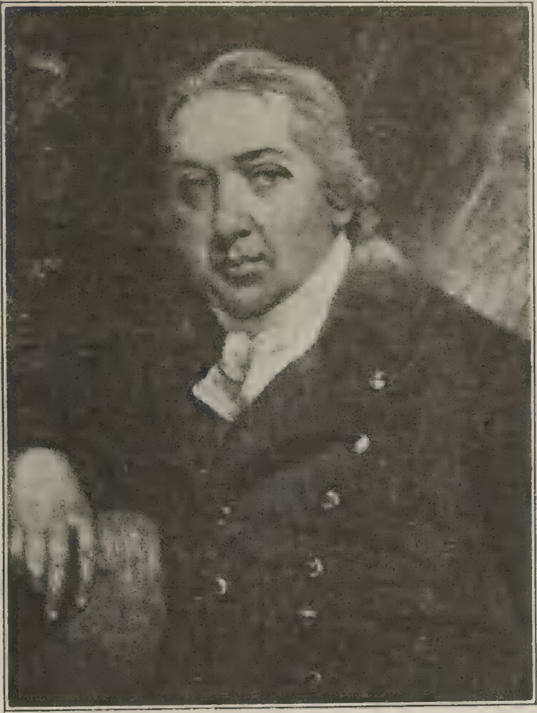
[4] It is remarkable that variolous matter, when the System is disposed to reject it, should incite inflammation on the part to which it is applied more speedily than when it produces the smallpox. Indeed it becomes almost a criterion, by which we can determine whether the infection will be received or not :— It seems as if a change which endures thro life, had been produced in the action or disposition to action in the Vessels of the skin ; & it is remarkable too, that whether this change has been effected by the smallpox, or by the cow-pox, the disposition to sudden cuticular inflammation is the same, on the application of variolous matter.

[21] Case 6th.

Although the preceding history pretty clearly evinces that the Constitution is far less susceptible of the contagion of the CowPox after it has felt that of the smallpox ; and although in general, as I have observed, they who have had the small Pox & milk Cows which are infected with the Cow-pox, either escape the disease or have sores on the hands only without feeling any general indisposition : yet the following narration is inserted to shew that the animal economy is subject to some variation in this respect.

In the summer of the year 1796 the Cow-pox appeard at the farm of Mr. Andrews, a considerable Dairy adjoining to the town of Berkeley. It was communicated, as in the preceding instance, by an infected Cow purchas'd at a Fair in the neighbourhood. The family consisted of the Farmer, his Wife, two sons, a Man & a Maid servant, all of whom except the Farmer (who was fearful of the consequence) bore a part in milking the Cows. The whole of them, exclusive of the Man Servant, had [22] regularly gone through the small Pox ; but in this case no one who milk'd the Cows escaped the infection. All of them had sores upon their hands, and some degree of general indisposition, preceded by pain and Tumors in the Axillae. But there was no comparison in the severity of the Disease as it was felt by the servant Man, who had escaped the smallpox and by those of the family who had not ; for, while he was confined to his bed, they were able, without much inconvenience, to pursue their ordinary business.

February the 13th, 1797 I avail'd myself of an opportunity of inoculating Wm. Rodway, the servant Man above alluded to. Variolous matter was inserted into both his arms, in the right by means of a slight incision, and into the left by Punctures. Both were perceptibly inflamed on the 3d day. After this the inflammation about the punctures soon died away, but a small appearance of erysipelas was manifest about the edges of the incision till the 8th day, when a little uneasiness was felt for the space of half an hour in the axilla.[5] The inflammation then hastily disappeared without producing the most distant mark of affection of the system.



Edward Jenner, from Scriven's engraving of the portrait by J. R. Smith (at the Wellcome Historical Medical Museum).

[23] Case 7th.

Elizabeth Wynne aged 57, lived as a servant with a neighbouring Farmer 38 years ago. She was then a Dairy-maid and the Cow-pox broke out among the Cows. She caught the Disease with the rest of the family, but, compared with them, had it in a very slight degree ; one very small sore only, breaking out upon the little finger of her hand, and scarcely any perceptible indisposition following. As the Malady had shewn itself in so slight a manner, & as it had taken place at so distant a period of her life, I was happy with the opportunity of trying the effects of variolous matter upon her Constitution ; & on the 28th of March 1797 I inoculated her by making two superficial incisions on the left arm, on which the matter was cautiously rubb'd. A little efflorescence soon appear'd and a tingling sensation was felt about the parts until the 3rd day, when both began to subside ; and so early as the 5th day, it was evident that no indisposition would follow.

[24] Case 8th.

Altho' the Cow-pox shields the Constitution from the small Pox, & the small Pox proves a protection against its own future poison, yet it appears that the human body is again & again susceptible of the infectious matter of the Cowpox, as the following history will demonstrate.

Wm. Smith, of Pyrton, in this Parish, contracted this disease when he lived with a neighbouring farmer in the year 1780. One of the Horses belonging to the Farm had sore Heels & it fell to Smith's lot to attend him. By these means the infection was carried to the Cows, & from the Cows it was communicated to Smith. One of his hands had several ulcerated sores upon it, and he became very ill with such symptoms as have been before describ'd. In the year 1791 the Cow-pox [25] broke out at another farm where he then lived, & he became affected with it a second time : & in the year 1794 he was so unfortunate as to catch it again. The disease was equally as severe the second & third time as it was on the first. In the spring of the year 1795 he was twice inoculated, but no affection of the system could be produc'd from the variolous matter; & he has since associated with those who had the smallpox in its most contagious state, without feeling any effect from it.

[26] Case 9th.

Simon Nichols lived as a servant with Mr. Bromedge, a Gentleman who resides in this parish, in the year 1782. He was employ'd in applying dressings to the sore heels of one of his Masters Horses, and at the same time assisted in milking the Cows. The Cows became affected in consequence, but the disease did not shew itself on their Nipples till several weeks after he had begun to dress the Horse. He quitted Mr. Bromedge's service, & went to another farm, without any sores upon him : but here his hands began to be affected in the common way, & he was much indispos'd with the usual Symptoms. Being here also employ'd in milking, the Cowpox was communicated to the Cows. [27] Some years afterwards, Nichols was employ'd in a Farm where the smallpox broke out, and I inoculated him with several other Patients, with whom he continued during the whole time of their confinement. The arm inflamed, but neither the inflammation, nor his associating with the inoculated family, produc'd the least effect on the Constitution.

Case 10th.

One instance has occurr'd to me of the System being affected from the matter issuing from the heels of Horses & of its remaining afterwards unsusceptible of the variolous contagion ; another, where the smallpox obscurely appear'd ; and a third, in which its complete existence was positively ascertaind.

1st. Thomas Pearce was the son of a Smith & Farrier near to this place. He never had [28] the Cowpox ; but, in consequence of dressing horses with sore heels at his fathers, when a lad, he had sores on his fingers, which suppurated and which occasioned a pretty severe indisposition. Six years afterwards, I inserted variolous matter into his arm repeatedly, without being able to produce anything more than slight inflammation ; which appeard very soon after the matter was applied, and afterwards expos'd him to the contagion of the smallpox, with as little effect.[6]

[29] Case 11th.

2ndly. Mr. James Cole a Farmer in this Parish had a disease from the same source as related in the preceding Case, and some years after, was inoculated with variolous matter. He had a little pain in the Axilla, and felt a slight indisposition for three or four hours. A few eruptions shew'd themselves on the forehead, but they very soon disappeard, without advancing towards maturation.

---

[5] Variolous matter inserted into the arms of those who have had the small Pox, will often produce sudden inflammation with a little pain & stiffness in the axilla.

[6] It is a remarkable fact & well known to many that we are frequently foild in our endeavors to communicate the smallPox by inoculation to Blacksmiths & Farriers. They often, as in the above instance, either resist the contagion entirely or have the Disease anomalously. We shall now be I presume able to account for this on a rational principle.

Case 12th.

3rdly. Altho' in the two former instances, the System seem'd to be secured, or nearly so, from variolous infection, by the absorption of matter from sores produc'd by the diseas'd heels of horses, yet the following Case decisively proves that this cannot be entirely relied upon until a disease has been generated by the morbid matter from the Horse on the Nipple of the Cow, & pass'd thro' [30] that medium to the human subject.

Mr. Abraham Riddiford a farmer at Stone in this parish, in consequence of dressing a Mare that had sore heels, was affected with very painful sores in both of his hands, tumors in each Axilla, & severe & general indisposition. A Surgeon, in the neighbourhood, attended, who assured him that he would derive one great benefit from his present situation, for, that he never need to fear the infection of the smallpox. But this assertion proved fallacious; for, on being expos'd to the infection upwards of twenty years afterwards, he caught the disease, which took it's regular course in a very mild way. There certainly was a difference perceptible, altho' not easy to describe [31] in the general appearance of the Pustules from that which we commonly see. Other practitioners, whom I requested to visit the Patient with me, agreed with me in this point, tho' there was no room left for suspicion as to the reallity of the disease, as I inoculated some of his family from the Pustules, who had the smallpox in consequence.

Case 13th.

The more accurately to observe the progress of the infection, I selected a healthy Boy about eight years old for the purpose of inoculation for the Cow-pox. The matter was taken from a suppurated sore on the hand of a dairy Maid who was infected by her master's Cows, and it was inserted, on the 11th of May 1796, into the arm of the Boy, by means of two superficial incisions, each about three quarters of an inch long. On the 7th. day [32] he complaind of uneasiness in the Axilla & on the 9th he became a little chilly, lost his appetite and had a slight headach. During the whole of this day he was perceptibly indispos'd, and had rather a restless night; but, on the day following, he was perfectly well. The appearance, and progress of the incisions to a state of maturation, were pretty much the same as when producd in a similar manner by variolous matter. The only difference which I perceived, was, that the edges assumed rather a darker hue, and that the efflorescence spreading 'round the incisions, took on rather more of an erysipelatous look, than we commonly perceive when variolous matter has been made use of for the same purpose.

On the 1st of July following, this Boy was inoculated with Matter immediately [33] taken from a smallpox Pustule. Several Punctures and slight incisions were made in both his arms, and the matter was well rubb'd into them, but no disease follow'd. The same appearances only were observable on the arms, as when a Patient has had variolous matter applied, after having either the Cow-pox, or the small Pox.[7]

[34] I presume it would be swelling this Paper to unnecessary bulk were I to produce further testimony in support of my assertion, "that the Cow-pox protects the human Constitution from the infection of the small Pox." I shall proceed then to offer a few general remarks upon this subject & some others which are connected with it.

Tho I am, myself, perfectly convinced, from a great number of instances which have presented themselves, that the source of the Cowpox is the morbid matter issuing from the newly diseas'd Heels of Horses, yet I could have wish'd, had circumstances [35] allow'd me, to have impress'd this fact more strongly on the minds of my Readers by Exper'ts. They who are not in the habit of conducting Experiments, may not be aware of the coincidence of circumstances, necessary for their being managed so as to prove decisive; nor, how often, Men, engaged in professional employments, are liable to interruptions which disappoint them almost at the instant of completion.

The active quality of the Virus from the horses heels is greatly increased after it has acted on the Nipple of the Cow, as it rarely happens that the Horse affects his Dresser with sores, and as rarely that a milkmaid escapes the infection when she milks infected Cows. It is most active at the commencement of the disease, before it acquires a Pus-like appearance, [36] after the disease has been of long continuance the matter ceases to produce specific effects. Whether the Matter, either from the Cow or the Horse, will affect the sound skin I cannot determine, but am inclind to think it will not, excepting where the cuticle is extremely thin, as on the lips. The hands of the farmers servants in this neighbourhood from the nature of their employments are constantly expos'd to those injurys which occasion abrasions of the Cuticle, to punctures from thorns, & such like accidents.

It is curious to observe, that this matter acquires new properties by passing from the horse thro another medium, that of the Cow; that its activity is hereby [37] increas'd, and that those specific properties become unvariable, which induce on the human Constitution symptoms similar to those of the variolous fever, and effect in it that peculiar change, which for ever renders it unsusceptible of the variolous Contagion.

May we not then reasonably infer, that the source of the smallpox is the matter generated in the diseas'd foot of a Horse, and that accidental circumstances may have again & again arisen, still working new changes upon it, until it has acquired the contageous and malignant form, under which we now commonly see it making its devastations among us? And from a consideration of the change which the infectious matter from the Horse has undergone [38] after it has produc'd a disease on the Cow, may we not conceive that many contagious diseases now prevalent among us, may owe their present appearance not to a simple but to a compound origin? For example, is it hard to imagine that the Measles, the scarlet fever, and the ulcerous sore Throat with a spotted skin, have sprung from the *same* source, assuming some variety in their forms according to the nature of their new combinations. The same Question will apply respecting the Yaws and the Syphilis, and indeed many other diseases.

There is certainly more forms than one in which the smallPox appears in what is call'd the natural way. About [39] seven years ago, a species of small-Pox spread thro' most of the Towns and Villages of this part of Glostershire. It was of so mild a nature, that a fatal instance was scarcely ever heard of, & consequently so little dreaded by most of the community, that they scrupled not to hold the same intercourse with each other, as if no infectious disease had been present among them. I never saw nor heard of an instance of its being confluent. It obtain'd the name among the Nurses & the common People (I know not why) of *the swine or Pig-pox.* The most accurate manner, perhaps, in which I can convey an idea of it, is, by saying, that had fifty individuals been taken promiscuously and infected by exposure to this contagion, they would have had as mild & [40] light a disease as if they had been inoculated with variolous matter in the usual manner. The harmless manner in which it shew'd itself could not arise from any peculiarity either in the season or the weather, for I watch'd its progress upwards of a year without perceiving any variation in its general appearance.

I consider it then as a variety of the smallpox.

At what period the Cow-pox was first notic'd here is not upon record. The oldest Inhabitants among the farmers were not unacquainted with it in their earliest days & have heard their forefathers speak of it (and have never heard it recorded).* Yet it is probable that its rise [41] in this Country, may not have been of very remote date, as the practice of milking Cows might formerly have been in the hands of women only; which I believe is the case now in some other dairy Countries, and, consequently, that the Cows might not in former times have been exposd to the contagious matter brought by the men servants from the heels of Horses. Indeed the fact itself, that is, a knowledge of the source of the infection, is new in the minds of most of the Farmers in this neighbourhood; but it has at length produc'd conviction; and probably from the precautions they now seem dispos'd to adopt (for a Farmer is not the most flexible of human Beings) the appearance of the Cow-pox here may either be entirely extinguish'd, or become extremely rare.

---

[7] During the whole time these Experiments were going forward, the Boy slept in a bed with two Children who never had been affected with either of these diseases, but neither of the Children became indisposd in consequence. A young Woman who had the Cowpox to a great extent, several sores that maturated having appear'd on her hands and wrists, slept in the same bed with a fellow dairy Maid, who never had been infected with either the small Pox or the Cowpox, but no indisposition follow'd. Another instance has come under my observation of a young woman, on whose hands were several large suppurations from the Cow Pox, and who was at the same time a daily Nurse to an Infant but the Complaint was not communicated to the Child.

* The words here placed in parenthesis appear in the MS. written immediately below the words "and have heard their forefathers," apparently as an alternative.—ED. L.

[42] Should it be ask'd whether this discovery (Investigation)† is a matter of mere curiosity or whether it tends to any beneficial purpose? I should answer, that, notwithstanding the happy effects of inoculation, with all the improvements which the practice has received since its introduction into this country, we sometimes observe it to prove fatal; & from this circumstance we feel, at all times, somewhat alarm'd for its consequences. But as fatal effects have been never known to arise from the Cowpox, even when impress'd in the most unfavorable manner, that is, when it has accidentally produc'd extensive inflammation, and suppurations on the hands; and as it clearly appears [43] that this disease leaves the Constitution in a state of perfect security from the infection of the small-pox, may we not infer that a mode of inoculation might be introduc'd, preferable to that at present adopted, especially among those families, which, from previous circumstances, we may judge to be predispos'd to have the disease unfavorably? It is an excess in the number of Pustules which we chiefly dread in the smallpox; but, in the Cowpox, no Pustules appear, nor does it seem possible for the contagious matter to produce the disease by effluvia or by any other means as I have before observ'd than *contact;* so that, a single Individual in a family might at any time receive it, without the risk of infecting the rest, or of spreading a disease that fills a country with Terror. [44] Without further research, I should therefore not in the least hesitate to inoculate Adults, and Children not very young, with the matter of Cow-pox, in preference to common variolous matter. How far it may be admissible on the tender skins of Infants, further experiments must determine. I have no other scruples than such as arise from the darkish appearance of the edges of the incisions in the arm of the Boy whom I inoculated with this matter, the only experiment I had an opportunity of making in that way. But in this Case, the incisions tho perfectly superficial were made to a much greater extent than was necessary for communicating the infection to the system. However it proved of no [45] consequence, as the Arm never became painful, nor required any application.

I shall endeavor still further to prosecute this Inquiry, an Inquiry I trust, not merely speculative, but of sufficient moment to inspire the pleasing hope of its becoming essentially beneficial to Mankind.

The bronze group by Giulio Monteverde in the Wellcome Historical Medical Museum, representing Jenner performing the first vaccination on the boy James Phipps ("Case 13th" in the accompanying paper) on May 14th, 1796, with material taken from the hand of the dairy-maid Sarah Nelmes, who had been infected with cow-pox. The group is sometimes erroneously referred to as "Jenner vaccinating his own child." Monteverde's rendering is, of course, purely imaginative; he never saw Jenner, and the boy Phipps was in reality eight years of age.

THE RAPID SPREAD OF VACCINATION.

The speed with which the knowledge of Jenner's work spread over Europe in the absence of any of the facilities with which we are now provided is very remarkable. In a Statement of the Progress in the Vaccine Inoculation, communicated to the *Medical and Physical Journal* for October, 1799, Dr. George Pearson, F.R.S., Physician to St. George's Hospital, writes:—

> "Not much more than six months have elapsed since the opportunity was afforded, by the breaking out of the *vaccine disease* in two principal milch-farms near London, of obtaining matter for propagating the same disease among human creatures. The *new inoculation* was immediately introduced in London, and soon afterwards in the neighbourhood, as well as in many provincial situations. It is with sincere satisfaction that we can now reckon, at the fewest, 2000 persons who have passed through the cow-pox by inoculation. . . .
>
> "The sensation excited on the continent by the vaccine inoculation has been much more considerable than even in our own island, as I learned first from Dr. Marcet, and since by a letter from Dr. Peschier. At Vienna, Dr. Ferro inoculated two of his own children with vaccine matter, which I transmitted; and next, Dr. De Carro inoculated two of his own children. An accurate journal of these two last cases was kept by Dr. De Carro, which he has had the complaisance to communicate to me through the hands of Dr. Peschier. The above patients had the vaccine disease in the usual mild way that they have had it in England, and were inoculated subsequently for the small-pox, but without taking that disease.

---

† The word "Investigation" is written immediately above the word "discovery" in the MS.—Ed. L.

"It is expected that Dr. Frank will adopt the new inoculation, as it is likely to be generally done at Vienna.

"I expect reports from Portugal and other parts of the Continent. . . .

"In Scotland, the new inoculation has not been less successful. Dr. Anderson, of Leith, informs me, he has inoculated above 80 persons; that Dr. Duncan, and others, have begun the practice at Edinburgh: and that it has been introduced in Dundee, Paisley and Dalkieth.

"If the vaccine inoculation proceeds with equal mildness as it has done the last four months, doubtless the variolous incision must in no remote period be superseded. And if such an event should take place, posterity will behold with amazement the prejudices and inattention of their predecessors to the application of a fact in practice, by which a formidable and loathsome disease was extinguished—a fact well known, time immemorial, to almost every farmer in half a dozen counties of England, but neglected till Jenner had the courage to indicate the advantages of it to society. If I were to name a parallel instance of inattention or prejudice, it should be the neglect of inoculation for the small-pox till it was introduced into England from Constantinople, although it had been practised time immemorial in the Barozzo mountains, on the frontiers of Gallicia, in the same rude manner that it is at this day."

JENNER CENTENARY.

At 8.30 P.M. on Friday, Jan. 26th, the centenary of Jenner's death will be observed at the house of the Royal Society of Medicine, 1, Wimpole-street, London, W. 1, when Sir William Hale-White, President, will give an address on "Jenner and his Work." A portrait of Jenner in oil colours by Hobday, presented by Dr. W. S. A. Griffith, will be on view, and Mr. C. J. S. Thompson, of the Wellcome Historical Medical Museum, will show Jenner relics.

A commemorative exhibition of personal relics, medals, books, MSS., engravings, caricatures, and other objects connected with Jenner and his work, will be held at the Wellcome Museum, 54a, Wigmore-street, W. 1, and will remain open for some months, daily from 10 A.M. to 5 P.M. All members of the profession and others interested are invited to view this exhibition.

INDUSTRIAL ANTHRAX.

AN INTERNATIONAL LABOUR CONFERENCE.

THE Advisory Committee on Anthrax convened by the Third International Labour Conference met in London from Dec. 5th–14th last. The Comimttee, which was chosen to include experts of the countries importing and exporting wool, was composed as follows:—Australia, Sir Thomas Oliver; Belgium, Dr. Glibert; France, Mr. Boulin; Germany, Dr. Frey; Great Britain, Sir William Middlebrook (chairman of the Departmental Committee on Anthrax); Italy, Dr. Loriga; India, Colonel Hutchinson; Japan., Dr. Konai; South Africa, Dr. Dixon; Spain, Prof. Rocca; Sweden, Mr. Ribbing: observer for the United States, Dr. Dorset.

The Committee was charged with inquiring into the problem of the disinfection of wool and hair suspected of being infected by anthrax; the most practical and effective methods of preventing infection among flocks; and the possibilities of dealing with infection by anthrax from hides, skins, and other suspected animal products.

The preliminary work of the Advisory Committee was summarised in a report of the Industrial Hygiene Section of the International Labour Office containing information from 27 countries. The chairman of the Committee distributed a pamphlet containing a survey of the results obtained in England during the last few years.

Infection from Wool and Hair.

After long and lively discussion, it was resolved:—

1. That hair used in the brush-making and upholstering industries shall be disinfected before the materials are handled industrially.

2. That wool and hair to be used in the textile industry shall be disinfected before the materials are handled industrially, except in the following cases: (*a*) If the country of origin is included in the schedule of countries where the danger is slight; (*b*) if the material to be imported has already been disinfected by a process recognised as effective; (*c*) if wools and long hair have to be sorted before washing, unless these products are not included in the list of harmless products; (*d*) in such other cases as may be determined by the Committee.

The experts who had come to give evidence agreed that the proportion of wool imported into England which does not require sorting before washing is extremely small, and that it is almost always this kind of goods which gives rise to the danger of anthrax among the workers; that if it were technically possible to sort the wools after washing, it would be bad from the commercial point of view.

Anthrax Among Flocks.

The Committee was of opinion that the best precautions against the danger of anthrax among flocks are at the present time the following:—

Compulsory notification and official verification of cases of anthrax.

Isolation of animals suffering from or suspected of suffering from anthrax.

The destruction of the entire carcass of any animals dead of or suspected to have died of anthrax, and disinfection of the immediate surroundings of the place where the animal has died as well as of the premises where it has been kept.

Preventive inoculation of animals against anthrax.

The Committee decided that the International Labour Office would have to study thoroughly this question in conjunction with the International Institute of Agriculture in Rome in order to arrive at some practical conclusions of an international character.

In the case of horns and hoofs the disinfection appears to be an extremely simple matter in practice, as they generally have to be treated by boiling, in order to be used for industrial purposes. In the case of bones, the Committee admitted that the industrial treatment to which they are subjected is generally equivalent to a disinfecting process.

Resolution.

The Committee agreed to adopt the following resolution:—

"The Committee is of opinion that in most countries the principal danger of industrial anthrax arises in the manipulation of hides and skins, and recognises the impossibility of securing at the present time complete disinfection to protect against this danger.

The Committee, therefore, recommends that regulations be laid down in the different countries having for their object the protection of the workers and the soil against infection by anthrax from hides and skins.

The Committee further suggests that the International Labour Office, in conjunction with the Health Committee of the League of Nations, should organise international research and invite nations and organisations chiefly interested to undertake such research in their respective countries.

The Committee considers that in view of the fact that all countries using infected materials will benefit by the discovery of a satisfactory process of disinfection it is desirable that the governing body should take into consideration the possibility of finding grants in aid of research undertaken for that purpose."

The final report of the Committee was drawn up by Dr. Glibert (Belgium) and Mr. Ribbing (Sweden) and adopted unanimously with the exception of one abstention and two votes withheld on a point concerning wools.

DONATIONS AND BEQUESTS.—Mr. John Philip Garnett, accountant, Manchester, left £250 to the Manchester Royal Infirmary, £250 to the Ancoats Hospital, £250 to Salford Royal Hospital, and £250 to the Christie Cancer Hospital, Manchester. The Manchester Children's Hospital has received donations amounting to over £1580, including £750 from Messrs. Peel and Co., Ltd., £250 from Booth Charities, and £150 from Dickanson's Charity. From a sum of £2120 received last year in Radcliffe for charities by collection in the mills and workshops, there has been allotted to the medical charities of Manchester and Salford £820, to Bury Infirmary £462, Bolton Infirmary £97, and Southport Convalescent Home £159, and lesser grants to other institutions in the county. Mr. Rowland Lowe, of Grand Rapids, U.S.A., has given £2000 to endow beds at the Ashton-under-Lyne Infirmary in memory of his parents.

THE LANCET.

LONDON: SATURDAY, JANUARY 20, 1923.

WAR BLINDNESS.

The number of combatants on the Western front in the late war who lost their sight appears to have been something like 10,000, and the methods adopted by the various countries in dealing with these unfortunates had much in common. Naturally there is local colour in the details. Dogs are used as blind guides in Germany, and blind stenographers have done better there than here; so much of difference may be gleaned from Captain Ian Fraser's interesting comparison of British and German methods which we published in a recent issue.[1] The total number of men who passed through St. Dunstan's, blinded directly or indirectly as the result of the war, estimated up to 18 months after the armistice, was 1833. Of these, 825 were under the care of Sir Arnold Lawson, the author of a book[2] which forms an important ophthalmological record of the war. The cases are analysed into various categories, a large number of short histories of the more interesting are given, and the book is completed by a chapter on disability pensions, and another on the plan of re-education adopted under the influence of Sir Arthur Pearson at St. Dunstan's. Of the cases under Sir Arnold Lawson's care only slightly under one-half were directly due to wounds. Of these, 72, or 17 per cent., were caused by through-and-through bullet wounds. In many of these the destruction of the second eye was due to partial or complete severance of the optic nerve behind the eyeball, and a new point brought out is that it is possible to distinguish by the ophthalmoscopic appearance whether the injury to the nerve took place immediately or at some distance behind the eyeball.

The more important section of the book concerns the 417 cases of non-traumatic blindness. The analysis of these is prefaced by some general remarks. First, it is not advisable to accept for active service any man whose defective sight in both eyes is due to old inflammatory disease of the uveal tract. No matter how quiet the eyes may be, or for how long the disease has been stationary, old inflammatory mischief is always apt to recrudesce under conditions inimical to general health. Secondly, even when one eye only has been affected in the past it must be taken into account that the other is always to some extent liable to attack. From this point of view cases in which one eye has been blinded by traumatism are more favourable than those in which the cause is syphilis, gonorrhœa, or septic infection. Thirdly, if a careful ophthalmoscopic examination of every man had been made prior to enlistment a large number of cases of active disease, congenital or acquired, would have been excluded, and a large amount of money saved in invalidity pensions. This fact should be of importance in pressing for a better ophthalmoscopic education for medical students than exists at present. Fourthly, the author remarks on the appalling share which must be allotted to syphilis of the total number of cases of disease-blindness. In the chapter on disability pensions the gradual increase of the pension rates during the war is recorded, and also the work of Sir Arthur Pearson on behalf of the appellants against unfavourable decisions of the tribunals. A large number of pensionless men gradually collected at St. Dunstan's. Appeals to the tribunals in 56 cases were successful in 48 instances. At first all unwounded cases of blindness due to syphilis, whether inherited or acquired, were refused pensions. It was largely owing to the strong advocacy of Sir Arnold Lawson himself that this attitude was subsequently changed. As he pointed out to the tribunal in a test case, the large percentage of blindness due to syphilitic optic atrophy in young soldiers was altogether in excess of what occurs in a similar class of syphilitic patients in civil life. The facts point absolutely to the conclusion that a large number of blind syphilitics owe their blindness indirectly to their service on behalf of their country, and that had it not been for such service very many now blinded would be enjoying good sight. Again, no less than 28 of the blind men who come under the heading of non-traumatic blindness suffered from retinitis pigmentosa. Of course, this ought to have been diagnosed when they were examined on enlistment, and the first decisions of the medical boards rejected them for pensions on the ground that their blindness had nothing to do with army service. All these men, however, were blind before they had reached the age of 40 years, and nearly half before they had reached the age of 25. Comparing this with the average age at which blindness becomes complete in this disease, it is very plain that this sad condition of these men, if not caused was very much hastened by the conditions of war service, a fact which was recognised later on by the pension appeal tribunals.

In the final chapter of this book the difficulties, and also the successes, of the re-education methods of St. Dunstan's are set forth. The large proportion of success was due partly to the fact that at St. Dunstan's the men were still comparatively young, and that in the great majority of cases their blindness was nearly complete. When the patient is over middle age and where he still possesses a certain amount of useful sight, though insufficient for the purpose of earning a living, the problem is far more difficult of solution.

◆

ON DISCLAIMING.

We printed last week a disclaimer by the medical author of a book, which had been designed solely for medical men, but which on its appearance received abundant notice in the daily press. We understand from the author that an interview, which did not take place at all, appeared in an evening paper, and he wished it to be known that he granted no interviews to journalists and that no copies of his book were forwarded to other than professional journals. We were glad to insert the disclaimer, although we doubted the need for doing so. No medical man, and certainly no colleague of the author's, supposed that he desired the kind of publicity which he obtained. This embarrassing notoriety was, we believe, entirely due to the chance coincidence that the book appeared shortly after a debate on surgical mistakes had taken place at the Royal Society of Medicine, from which representatives of the lay press, who wished to be present, were excluded. However much an author may regret unprovoked publicity, he is often entirely unable to prevent it, and this is a fact which gives renewed point to the comment which we recently felt it necessary to make upon the debate on indirect advertisement at the General Medical Council. We then took as an example a well-known consultant, called in to the case of a public person, whose name appeared prominently on this account. In a letter to our columns this consultant justly indicated that the point of censure is not the fortuitous appearance of a doctor's name in the lay press, but neglect to do his utmost to prevent its appearance there. Neither in the case of physician to the well-known man, or in that of the book which has caught the popular eye, does the slightest question arise of oblique advertisement. The circumstances in which the name of a medical man comes prominently forward in the lay press are themselves the best clue to whether notoriety was obtained by the practitioner for himself or was thrust upon him. No disclaimer, whether in our own columns or elsewhere, can improve on the effect of a transparently honest case or do much to mitigate suspicion where the circumstances are equivocal. The increased interest which is being taken—and, we think, rightly taken—in medical matters by the lay press must result in a more frequent appearance of the names of individual medical men and women. For this reason we shall not in the future consider it necessary, apart from exceptional circumstances, to print such disclaimers as appear in our issues of Dec. 16th and Jan. 13th.

---

[1] The Lancet, Jan. 6th, p. 44.

[2] War Blindness at St. Dunstan's. By Sir Arnold Lawson, K.B.E., M.D., F.R.C.S., Senior Ophthalmic Surgeon and Lecturer in Ophthalmic Surgery, Middlesex Hospital. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1922. Pp. 148. 7*s.* 6*d.*

We contemplate ourselves without alarm the growing interest taken by the public press in medical matters, and we should hesitate to dictate the method of journalistic treatment of medical matters which naturally differs widely from that of a professional journal. The rapid news service of the lay press can be of great value in case of epidemic disease, and is freely utilised by sanitary officers and others. But the centre of interest waxes and wanes like a comet, and medical reports in the daily press, even where the papers are well-informed, lack the continuity of orderly discussion. This is not to say that so long as the interest lasts it may not be well directed. The Sunday paper which made most of the details of surgical mistakes, to the possible extent of alarming the public, ended with a reasonable and proper assurance: "The advent of this book," said the *Weekly Dispatch*, "whilst disturbing to the timid, should in reality reassure them. It makes it clear that with the vast majority of cases incorrect diagnosis or execution is the exception rather than the rule." Frankness breeds frankness, and it is well for the public to know that there are many other factors involved in the successful treatment of a particular case than the surgeon's individual skill. Promising medical careers have been before now tragically blighted by public misunderstanding of a fatal result in what appeared to be a promising case. Reports of inquests and police-court proceedings light up cases where medicine has failed, but without necessarily being in any way to blame for failure. Physicians and surgeons with reputation well established and with nothing to lose from candour are often willing to disclose to the world their early mistakes, glorified it may be by the lapse of time and the desire to tell a good story at their own expense. We have often regretted the absence from our own columns of recorded instances of failure in regard to methods of treatment which, by common knowledge, are not universally successful. Assurance of absolute candour on the part of the medical man in regard both to successes and failures would, we believe, raise in popular esteem the present-day methods of medical practice from which some of the mystery of a more credulous age has been rubbed away.

THE DUMPING OF REFUSE.

IN his last report on the health of Manchester Dr. JAMES NIVEN draws attention to the bad policy of tipping organic refuse within the city area. Mr. BERNARD SHAW's amusing but perfectly serious letters concerning the dumping of London refuse near his country house in Hertfordshire raise the sanitary and ethical questions involved in fouling your neighbour's land. The dumping of refuse from London in the Home Counties periodically comes up for consideration and discussion, but we do not find that there is any abatement of the evil. Dumping is wrong in principle, as it is quite opposed to the interests of public health, and is uneconomical, although it may prove of agricultural value to the contractor who receives the refuse if, as is frequently the case, he is also a farmer. Refuse dumps, for some time after the refuse has been deposited, are a definite menace to public health. Included in the refuse is a considerable amount of old and discarded clothing, bed-clothing, pillows, and mattresses, and these are potentially a medium for the transmission of infectious disease. Dumps also provide an excellent breeding ground for rats and flies. The ætiological relationship between rats and certain diseases of man and animals is well known. As a carrier of the specific organism of certain diseases, the fly occupies a well-recognised position, and complaints are frequently received from people residing in the vicinity of large refuse dumps regarding the nuisance occasioned by large numbers of these pests. The firing of dumps not infrequently gives rise to a very disagreeable and irritating nuisance. Refuse dumps may be set on fire intentionally with a view to the destruction of organic and combustible material, but usually the firing is caused accidentally from the careless use of matches or from spontaneous combustion. Whatever the cause, the result is the production of acrid and irritating fumes, which, with a strong wind, are carried a considerable distance and may prove to be a source of considerable annoyance and irritation to people residing in the district. Combustion, however, is to some extent beneficial, as it destroys the organic matter upon which the presence of rats and flies depends, but once commenced it is very difficult to control and the dump may smoulder for an indefinite period. The Ministry of Health fully recognises the essential badness of disposal by tipping, and recently issued a circular to local authorities setting out how the nuisances may be, to some extent, prevented by careful management.

From the public health point of view the best method of dealing with the house refuse is by incineration in a destructor, and this method should not be beyond the means of any borough possessed of a respectable rateable value. Glasgow long ago washed its hands of slipshod and offensive methods. Up to the year 1868 house refuse lay about in open depots until it was carted away by the farmers. Now cremation of the refuse drives clinker crushing and screening plant and supplies hot water for baths and lavatories, while at the refuse despatch works a valuable fertiliser is produced known as "prepared city manure." A number of English boroughs have since followed this good example. But the disposal of refuse by dumping on the land unfortunately is likely to be continued in many districts for some time to come. To safeguard the interests of the public health and the amenities of pleasant country districts, Dr. H. H. THOMSON has recently suggested to the Hertfordshire County Council that the conditions under which house refuse is conveyed and dumped in rural districts should be clearly defined. Three conditions are essential: (1) the conveyance of refuse in covered railway wagons; (2) the keeping of the surface of the dump level, and the covering of all refuse, new and old, with nine inches of soil; (3) permission from and supervision by the council of the county where refuse is deposited by an authority outside the county area. At present the local sanitary authority is responsible. The enormous amount of refuse which has to be dealt with from a city of the size of London raises the question of the possible commercial value of house refuse. If its immediate conversion into some commercially useful material could be made a practical proposition, an important problem in relation to public health would find a much-needed solution.

Annotations.

"Ne quid nimis."

THE HYGIENE OF LAUNDRY-WORK.

The laundry trade has been one of the last industries to be factorialised, and even yet the customers of a laundry continue to be its keenest rivals. A rise in charges or depression in trade causes the washing to be done at home. In the past the conditions of laundries in cramped and unsuitable premises have been justly condemned; but modern laundries built for the purpose are economically so efficient that they are supplanting older premises. Nevertheless the trade still presents enormous diversity from a specially designed factory to some modified stable. An investigator aiming in such an industry at determining the effect exerted upon the workers of their work is faced with innumerable difficulties. Miss May Smith has essayed the task for the Industrial Fatigue Research Board, and a report[1] upon her inquiry is now published. First, an effort was made to study the workers at work by scientific observation. The time interval in performing given tasks was chosen as a measure; it was found to be longer during a day of ten hours' work than one of nine hours at different laundries and at different processes, and it lengthened as the end of the afternoon approached. No evidence, however, was obtained that fatigue accumulated from day to day, or that a reduction of hours increased the total output. Fatigue among the workers, so far as productivity is concerned, appears to be submerged in the question of efficient organisation, such as regulation of the supply of articles, placing well-matched girls to work together, or replacing involuntary and irregular stoppages by definite rest pauses, as, for instance, a ten-minute interval for tea. Details of accurate time measurements are given to justify these conclusions.

Workers were also studied by the psychological "dotting" test. Observations upon individual operatives showed that conditions of work and physical well-being actually have effects which can be measured, for performances at the test improved or deteriorated with such things as interesting or monotonous work, with healthy vitality or the presence of sick headaches. When the observations were grouped for workers at different processes the number of errors was found to be from 10 to 20 per cent. greater in the afternoon than in the morning; it was larger in later hours of the afternoon than in earlier; it was smallest on Tuesdays and Wednesdays, and largest on Thursdays and Fridays (Saturday being a half-day is excluded from the observations). Atmospheric conditions were investigated in a number of laundries by using the kata-thermometer. When these observations, which are given in detail, are compared with those collected in other trades, like potters' shops, boot and shoe factories, and weaving sheds, the air of laundries is found to have a low cooling power, too low to be physiologically stimulating. Improvement in this matter appears to be an insistent problem in laundries. We regret that no effort is reported to discover how activity is affected by the prevailing conditions. But the comparison here made with other industries is of great import; it demonstrates how the research work of the Board increases in value as industry after industry comes under review. Miss Smith, after discussing the scientific data collected, makes common-sense observations upon matters which cannot be submitted to accurate measurement. Attention is drawn to unnecessary irritation to workers caused by defective organisation within particular processes, or by unsympathetic forewomen who command no loyalty; to the advantage of changing occupations in order to escape from long repetition of some wearisome movement, such as back-bending; to the need for seats during temporary lulls in work; to the mistake of allowing girls who are on their feet all day to wear shoes with narrow toes and high heels instead of strong Lancashire clogs; to the urgent call for adapting machines to workers and not leaving manufacturers to supply what seems to them appropriate; and to the existence of monotony fatigue, that type which says, "I'm not tired, but I'm tired of this."

The report throughout gains much from the way in which the personality of the workers is permitted to appear; it is more than an exposition of a scientific research; it is a very human document.

EARLY PHLEBITIS IN PULMONARY TUBERCULOSIS.

Prof. Lafforgue,[1] of the Toulouse Faculty of Medicine, remarks that the mention of phlebitis in pulmonary tuberculosis usually suggests the phlegmasia which occurs at an advanced stage of the disease, whether associated or not with cachexia. This form of phlebitis, of which a classical description has been given by Vaquez and Widal, is by far the most frequent, whereas comparatively little is known of the phlebitis which appears in the early stage of pulmonary tuberculosis. In the course of his long career Prof. Lafforgue has seen only two examples of this early form and barely 20 cases have been recorded in French literature. Some well-known authorities such as Laveran have even denied its existence. The first important description of early tuberculous phlebitis appears to have been given by Hirtz at a meeting of the Medical Society of the Paris Hospitals in 1894, since when several Paris theses have been devoted to the subject. The complication may develop in the following distinct types of tuberculosis. The first type is composed of persons who are free from any obvious symptoms of tuberculosis, though on close examination evidence of the disease will be detected in the lymphatic glands, especially the tracheo-bronchial group, the hila or apices of the lungs, or in the pleura. The second group consists of persons in the initial stage with slight but definite signs in the lungs. The third type is represented by sero-fibrinous pleurisy, and the fourth by an abnormal form of tuberculosis simulating chlorosis. Early phlebitis shows a marked predilection for the lower limbs affecting each with equal frequency. As a rule it is unilateral, but occasionally it involves both sides, either simultaneously or much more frequently one side 10 or 20 days before the other. The superficial veins are principally involved, the internal saphenous in half, and the external saphenous in one-fifth of the cases. The femoral is occasionally affected, either primarily or by spread of inflammation from the saphena, but much less frequently than is estimated by some statistics. The onset is usually gradual, being characterised by pain which, as a rule, is moderate but progressive in character, and is followed from a few days to a week later by œdema, which is

---

[1] Some Studies in the Laundry Trade. By May Smith. Industrial Fatigue Research Board. Report No. 22. 1922.

[1] Paris Médical, Jan. 6th, 1923.

always of slight extent unless the femoral is involved, when it is more pronounced and persistent. In the neighbourhood of the œdematous area, and usually above it, the thrombosed segment of the vein can be felt. The rise of temperature is usually slight and transient and is not accompanied by shivering or constitutional disturbance except in phlebitis of the deep veins, when a temperature of 104° F. may be registered. Early tuberculous phlebitis is further characterised by absence of a collateral circulation, very slight impairment of function, and absence of cutaneous sensory changes or of trophic or vaso-motor disturbances which are found in other varieties of phlebitis. As regards the diagnosis, apart from the exceptional cases in which the phlebitis is unilateral, there is little chance of the œdema being mistaken for that due to cardiac or renal disease or mechanical causes. But when pain is the principal feature and the other symptoms are in abeyance, the phlebitis may be mistaken for peripheral neuritis or arthritis. When once the diagnosis of phlebitis is established its nature must be determined, and such causes as chlorosis, rheumatism, gout, gonorrhœa, typhoid, and especially syphilis must be excluded. The immediate prognosis of early phlebitis is favourable, especially as there is no likelihood of embolism. On the other hand, the remote prognosis is often very grave and should always be guarded. In about one-third of the cases acute generalised tuberculosis ensues at any time from a few months to two years from the appearance of the phlebitis. In about the same proportion of cases in place of an acute generalised tuberculosis there is a marked aggravation of the initial lesions and a more or less rapidly fatal issue takes place. It is only in a few instances that the pulmonary lesions remain stationary. The treatment does not differ from that of other forms of phlebitis. In spite of the rarity of embolism it is advisable to immobilise the limb until the acute symptoms have subsided, and in view of the likelihood of acute tuberculosis appropriate measures should be adopted.

THE APOTHECARIES' GARDEN AT CHELSEA.

There is a passage in the Agricola where Tacitus adjures his father-in-law with that "organ voice" which he possessed in common with Milton; "Si quis piorum manibus locus, si, ut sapientibus placet, non cum corpore extinguuntur magnæ animæ, placide quiescas. . . ." The spirits of bygone apothecaries, of Sir Thomas More, of Sir Hans Sloane, of Linnæus, and many another botanist and physician might well be gladdened by a recently published account of the apothecaries' garden at Chelsea by Dr. F. Dawtrey Drewitt.[1] The Physic Garden at Chelsea is now safe, in so far as anything may be safe in these days of unrest, from the builder and the kinema company monger, and we may reasonably hope will remain as an oasis in the desert of houses and a place where students of nature may study. For the detailed history of the garden we must refer readers to Dr. Drewitt's book, but briefly it began its existence in 1673 when the Apothecaries' Company which had separated from the Grocers' by order of James I. in 1617, feeling the need of a garden where they could "cultivate rare plants, and sow seeds now coming in from foreign lands" leased three acres of land from Charles Cheyne, afterwards Lord Cheyne, for £5 per annum, in the then riverside village of Chelsea. From the first there were difficulties in finding money for the upkeep, and although early in the eighteenth century Lord Cheyne had offered the Company the freehold for £400, this was a sum far beyond their means. In 1713 the Company were hard pressed, but by the sale of some South Sea Stock "with advantage," and by a tax on masters and apprentices, they managed to keep the garden going. But in 1712 Sir Hans Sloane had bought the Manor of Chelsea, so that he was now the Apothecaries' landlord, and him they consulted in their trouble. Being a just as well 1722 a deed was signed by which Sloane undertook in as a learned man, he heard their complaint, and in consideration of a yearly rent of £5 to convey the Physic Garden to the Company for ever, together with its stoves, green-houses and barge-houses, to enable the Society to support the charge thereof, "for the manifestation of the power, wisdom, and glory of God in the works of creation and to show how useful plants may be distinguished from those that are hurtful." So matters went on until the year 1893, when the Apothecaries' Company reluctantly decided that they could no longer bear the expense of keeping up the garden. Neither the Royal Society nor the Royal College of Physicians of London would accept the reversion of the garden, so the Apothecaries handed it over to the Charity Commissioners. By Sir Hans Sloane's will the garden reverted to his heirs so soon as it should cease to be used for scientific purposes, so there was every prospect of the site being used for building. In this crisis Lord Meath, the Director of Kew Gardens (Sir W. Thiselton Dyer), and others urged upon the Treasury that the garden was of importance to all students of botany, and eventually a committee was appointed to superintend its management, the members of which are appointed by or represent the London Parochial Charities, the Treasury, the London County Council, the Royal College of Physicians, and other bodies. Income for upkeep comes from the London Charities, the Royal College of Physicians, London University, and other bodies. Dr. Drewitt's pages teem with information about the history of the garden, its curators, its distinguished visitors, its trees and plants, and the "herborising" excursions which the demonstrator and the apprentices of the Apothecaries' Company carried out. These continued until the "fifties" of the last century, and an amusing account of them will be found in one of Albert Smith's now forgotten novels.

THE BLOOD AND CANCER RESEARCH.

The problems of cancer, so fascinating in their complexity, obstinately resist the attack of the research worker to the extent that it is a matter for wonder that men can be found willing to devote their lives to them. The chances of reaping a just reward for prolonged conscientious and often exceedingly arduous work are indeed remote; more often the end attained is only the blocking of a further avenue of research for subsequent investigators. Yet there is consolation in the fact that though the secrets of malignant growth are revealed so grudgingly, inroads into this field of knowledge are surely, if slowly, being made. Some recent work[1] by J. B. Murphy and E. Sturn on the conditions of growth of heteroplastic tumour tissue in brain substance, seems to show that such growth is possible only because foreign body reaction changes do not take place around the grafts, as they do when inoculation is performed subcutaneously. Lymphocytes appear to take a very active part in the destruction of this foreign tissue. Growth is also prevented, if a portion of the animal's own spleen be introduced into the brain with the alien tumour tissue. Previous researches by J. B. Murphy,[2] had established two other facts: (1) that foreign tumours can be carried through several generations in irradiated animals; and (2) that adult animals deprived of a large portion of lymphoid tissue are also deprived of their ability to destroy foreign tissue. The profound changes in the leucocytes found in X ray workers and their susceptibility to malignant disease are well known, whilst massive deep radiation for the cure of cancer is on its trial. It is interesting to speculate in view of the violent constitutional reactions which take place, and the pronounced changes which occur in the blood as a result of exposure of the body to X rays, whether the results claimed to be got by deep radiation could not equally well be obtained by the intense radiation of the spleen, and perhaps of the bone marrow, and whether the origin of malignant disease may not be related with some waning physiological powers of the lymphocytes, even if their numbers remain the same. We know little indeed of the properties and activities of these elements of the blood. It looks as though another field of research had been thrown open.

[1] The Romance of the Apothecaries' Garden at Chelsea. By F. Dawtrey Drewitt, M.A., M.D., F.R.C.P. Lond.

[1] Journal of the American Medical Association, 1922, lxxix., 2159.
[2] Journal of Experimental Medicine, 1914, xix., 513.

SHOULD TREATMENT FOR ULCERS OF THE STOMACH AND DUODENUM BE MEDICAL OR SURGICAL?

BEFORE this question can be answered satisfactorily, reliable answers to a number of other questions are required. Indeed, the whole subject bristles with question marks, which emphasise our lack of reliable data. At present we cannot even approximately estimate the chances of fatal complications when no operation is performed, nor can we say how often, and in which cases, skilled medical treatment effects a permanent recovery. How frequently, and to what extent are the patient's health and working capacity reduced by ulcer symptoms, and what are the end-results of surgical treatment? The three complications which, more than any other, have swept cases of gastric and duodenal ulcer out of the hands of the physician into those of the surgeon are malignant degeneration, fatal hæmorrhage, and perforation. A few months ago Dr. N. A. Nielsen[1] of Copenhagen, showed in a masterly review of the subject that the chances of malignant degeneration of gastric and duodenal ulcers have been much exaggerated, and his researches suggest that, though malignant disease of the stomach and duodenum often masquerades for a time as simple ulcer, it is comparatively seldom the final stage of chronic ulceration. In a more recent publication[2] he has dealt with the chances of ulceration of the stomach and duodenum terminating in fatal hæmorrhage, and the prospects of aborting this issue by operative interference. As his analysis of the large material at his disposal at the Rigshospital in Copenhagen indicates, fatal hæmorrhage is not only comparatively rare, but it also shows a remarkable tendency to attack persons who have previously shown slight or no symptoms beforehand. And if there had been slight symptoms beforehand, they had lasted only a short period. Obviously in these cases, even the discussion of an operation as a prophylactic measure against fatal hæmorrhage is unthinkable, considering how common are slight and transitory digestive disturbances. Dr. Nielsen has collected 55 cases of fatal hæmorrhage, observed between 1907 and 1917 in Copenhagen, and the post-mortem records showed that in 16 cases the fatal hæmorrhage came from a recent ulcer or erosion, and in 11 other cases the source of the hæmorrhage was also a recent ulcer, although other, old ulcers, were also found. In seven cases the post-mortem records were incomplete, and only in 21 cases did the fatal hæmorrhage come from a chronic ulcer. Most of the 27 patients who died of hæmorrhage from a recent ulcer were elderly; the age of 20 of the patients was between 40 and 76. The quasi-paradoxical conclusion to which Dr. Nielsen comes is that though only about a quarter of all the ulcers of the stomach and duodenum develop after the fortieth year, yet about three-quarters of all the fatal hæmorrhages from recent ulcers occur in patients who have passed the fortieth year. No doubt the capacity of a bleeding artery in this region to contract diminishes with age, and this is Dr. Nielsen's solution to his paradox. He has traced 182 patients, discharged from hospital two and a half to 19 years earlier, the diagnosis of gastric or duodenal ulcer during their residence in hospital being of a searching and reliable character. The treatment given in hospital was strictly medical. His investigations showed that 42 had subsequently been operated on, but in no case was the operation for severe hæmorrhage or free perforation. Of the remaining 140 patients, 16 were found to have died, but only in two cases was death due to hæmorrhage, and in none was it due to free perforation. Hence Dr. Nielsen's conclusion that the surgeon is hardly justified in recommending operative treatment to patients suffering from gastric and duodenal ulcer merely on the ground that they may possibly die of hæmorrhage.

RUSSIAN EPIDEMIOLOGISTS IN CONFERENCE.

THE sixth All-Russian Congress of Bacteriologists and Epidemiologists was held at Moscow last May. It is the only scientific Russian congress which has met every year since the revolution, and it is allowed to meet as the need for it is always felt since epidemics are continually sweeping through Russia. Only meagre accounts of this congress have been as yet available, but a good account is now given by Prof. P. Mühlens, of Hamburg, in the *Archiv für Schiffs- und Tropen-Hygiene* (xxvi., 8). Four hundred Russian doctors were gathered in from all parts of the country, and with them the members of the German Sanitary Commission. Gratitude was expressed to the foreign missions for their help, the problems of these diseases being felt to be too great to be solved by the unaided efforts of Russia herself. Typhus, which had been decreasing, began to spread itself more widely as soon as the famine conditions became acute, in the winter of 1921. It was most prevalent in the Volga provinces, and it spread chiefly from the hospitals and along the lines of the railways, whose staffs suffered heavily, and particularly the doctors. Prof. Barykin, of Moscow, reported that he had found the causal organism. Nothing is said of an accepted and effective method of treatment of the disease. Relapsing fever was treated best by neosalvarsan on the fifth day of the interval. Dr. E. I. Marzinowsky, director of the Moscow Institute of Tropical Diseases, wrote describing the development of the spirillum as he had seen it. Relapsing fever in Russia is often associated, in a novel syndrome, with a paratyphoid fever, caused by yet another *Bacillus paratyphosus;* this syndrome has a 50 per cent. mortality and is reported also from Poland, Rumania, and Asia Minor. Malaria has enormously increased in these later years and is extending itself farther and farther to the north. The congress was very anxious about this widening of the area in which malaria is become endemic, asking for better statistics, more information about the migration of mosquitoes; asking that infected troops and civilians shall be excluded from districts hitherto immune; asking for special antimalarial centres all over the country, under supervision of the Moscow Tropical Medicine Institute, and staffed by specialists; asking for schemes for drainage of swamps, and for more information about the winter epidemics of malaria, which specially attack men who are cutting turf. Plague was giving great anxiety in south and south-east. Leprosy was spreading so extensively that leper colonies are required with accurate registers of patients, and with schools and hospitals. Three thousand cases of cholera had appeared before the middle of May, thrice as many as in 1921. In the winter it was not water-borne, but had spread by personal contact. Preventive inoculation was recommended—starving people can only stand small preventive doses—though many carriers are found among the inoculated. The final resolution asserted that the famine area was far larger than the official reports admitted; that the famine was a chief cause of the prevalence of the epidemics, and that the assistance for the distressed obtainable within Russia herself was quite insufficient for her needs. In consequence the congress begged for help from Western Europe and from America. "The very richest of our districts are becoming deserts. Our cities and villages are dying out. Forty millions are starving. The condition of Russia is a menace to Europe, so we beg all professional and sanitary organisations in Europe and America to come to our aid." Delay in report of this congress is the less material as conditions in Russia in regard to famine and pestilence are much the same as they were eight months ago.

CINCHONA FEBRIFUGE.

IN his annual report for 1921 of the Institute for Medical Research, Kuala Lumpur, Federated Malay States, a section is devoted by Dr. William Fletcher to a discussion of the merits of cinchona febrifuge in the treatment of malaria. Cinchona bark was brought to Europe in 1638, and a decoction was used empirically for the treatment of ague for nearly 200 years before its active principle was isolated, and only of comparatively recent times has the exclusive employment of one of its alkaloids—quinine—become customary. The report recalls Major H. W. Acton's experiments carried out at the British Malaria Convalescent Depôt at Dagshai, in the Himalayas, suggesting strongly that the mixed alkaloids are less toxic than quinine, and superior to it in the treatment of tertian ague. At Dagshai there was no chance of reinfection with malaria; Major Acton's patients were all soldiers, who were kept under observation for eight weeks after they had finished their course of treatment. The preparation used was cinchona febrifuge, containing the total alkaloids of cinchona bark, made at the Government quinine factories at Mungpoo, in India. The average composition of cinchona febrifuge is as follows: Crystallisable alkaloids (54·65 per cent.), quinine 7·40, quinidine 22·83, cinchonine 18·58, cinchonidine 5·84 per cent.; uncrystallisable alkaloids, ash, &c., 45·35 per cent. It is estimated that nearly 20,000 lb. of quinine are imported annually into British Malaya; quinine costs at least $28 a pound, whereas cinchona febrifuge costs less than $7 a pound, so that an enormous saving would be effected by the substitution of the unseparated mixture for general use. In the light of Major Acton's findings, Dr. Fletcher undertook experiments at Kuala Lumpur, where, however, the question of permanent cure was difficult to investigate—first, because patients might there become reinfected whilst under observation after the conclusion of treatment, and, secondly, because it was impossible to persuade patients to remain in hospital for two months after they had completed a four weeks' course of treatment. Only a small amount of the Indian cinchona febrifuge was available; its immediate effects upon malaria were found to be as powerful as those of quinine.

Another preparation containing the total alkaloids derived from Javan cinchona bark, also sold under the name of cinchona febrifuge, is made by the Bandœngsche Kininefabriek Company. The average composition is stated by the makers to be as follows: Crystallisable alkaloids (62·8 per cent.), quinine 11·5, quinidine 5·0, cinchonine 26·3, cinchonidine 20·0; uncrystallisable alkaloids, ash, &c., 37·2 per cent. A quantity of this Javan preparation was obtained and tested upon a small number of patients suffering from quartan malaria, which form of the disease is more rare, and probably more liable to relapses, than the tertian fevers; the number of patients, 23, was kept small in order to facilitate strict personal supervision of the treatment. These 23 patients were given 10 gr. cinchona febrifuge twice a day for four weeks in cylindrical gelatin capsules (number 0); an average of 21 ordinary and 13 thick blood films were examined during the four weeks of treatment in each case. Fifteen of the patients were suffering from quartan malaria, and the remainder from malignant or benign tertian, or mixed quartan and tertian malaria. In every case administration of cinchona febrifuge stopped the fever before the fifth day of treatment, and caused the disappearance of the parasites, although in three quartan cases the latter were found in ordinary films up to the fifth, sixth, and seventh days respectively, whilst in one case they were found in thick films as late as the eleventh day, but not subsequently. The immediate effect of the febrifuge was thus found to be equal to that of quinine. Sixteen patients were willing to remain in hospital for three weeks after the conclusion of their treatment; although from the statements of Acton and Stephens at least 10 of the 16 patients might have been expected to develop fever during these three weeks of observation, only four did in fact do so, and of these four two were probably fresh infections. It was therefore concluded that the permanent therapeutic effects of the Javan cinchona febrifuge are at least as good as those of quinine; and its toxicity was found to be no greater than quinine toxicity. Dr. Fletcher closes this section of his report with a warning to the effect that cinchona febrifuge is not an official drug, and that until its composition has been legally defined, powders deficient in alkaloids, or containing harmful alkaloids, may be sold under that name.

THE “WEEKLY RETURN.”

WE remind our readers of the Weekly Return of Births and Deaths issued by the Registrar-General, which has just entered on its second year of publication in a new and attractive form. Table I. shows the births and deaths each week in the 105 great towns, with the numbers of fatal cases of fevers and the deaths of infants under 1 year of age. Table II. gives the same information for certain cities in the British commonwealth of nations and in foreign countries. Table III. classifies in greater detail the causes of deaths occurring in London. Table IV. sets out the notified cases of infectious diseases throughout the sanitary areas of the country. Table V. gives a conspectus of notified cases and deaths from certain important infectious diseases for each week in the preceding quarter. Tables VI. and VII. are meteorological. During the week ended Jan. 6th there were notified, in the whole of England and Wales, 12 cases of small-pox, 2269 of scarlet fever, 1063 of diphtheria, 43 of enteric fever, 968 of pneumonia, 124 of ophthalmia neonatorum, 46 of puerperal fever, and 13 of encephalitis lethargica. Of the less frequent infections there were notified 9 cases of dysentery, 7 of cerebrospinal fever, 3 of acute poliomyelitis, and one each of acute polio-encephalitis and “continued fever.” Table IV. makes it readily possible for anyone to ascertain at a glance the distribution of these infectious diseases throughout the various urban and rural districts of England and Wales. Table II., with its information regarding the cities of the British Empire and foreign countries, gives a graphic picture from week to week of the public health and social conditions prevailing throughout the world. The price of the Weekly Return is 1*s.* a copy. It is published by the Stationery Office and may be obtained through any bookseller. Its perusal will well repay the cost.

PROPOSED TESTIMONIAL TO DR. BYROM BRAMWELL.

THE news that Dr. Byrom Bramwell of Edinburgh has attained his seventy-fifth birthday and that it is proposed to mark the occasion by the presentation to him of an appropriate testimonial will be welcomed by all old Edinburgh students, as well as by many others of the profession who know him personally, or through his contributions to scientific medicine. For many years Dr. Bramwell, together with several other physicians now, unfortunately, no longer surviving, carried the reputation of the Edinburgh school, on the medical side, to a level which, if we are to take world-wide appreciation as a criterion, has not been equalled before or since. When these men were in their prime no school could boast a finer galaxy of scientific stars. Only Dr. Bramwell remains to-day, and if his working days are over no one who ever laboured with him, or was taught by him, is likely to forget the association with one in whom has been combined the breadth of knowledge of the savant with the practical equipment of the bedside physician. Sometimes men who "sit under" such a teacher are too near him for due recognition of his great qualities; the lapse of time and the added factor of distance serve to bring into their true proportions the bigness, and the enduring influence, of the mind which can awaken in others the love of knowledge for its own sake, which can mould to the best purpose the impressionable character of the eager aspirant at the outset of his chosen career. The Provisional Committee for this testimonial is headed by the names of the leaders of the profession in this country—a sufficient indication of the respect and admiration with which Dr. Bramwell is regarded. Comparatively little public recognition of the honoured place Dr. Bramwell holds in the profession has fallen to his share during a long and active life; it is the more desirable, therefore, that in the days of his retirement all who have come in contact with him in any way should unite to put on record and to convey to him by suitable means their appreciation of his worth as a great physician, a great teacher, and a great gentleman.

THE RELATIONSHIP OF MEDICINE AND TOXICOLOGY.

IN the Presidential Address delivered to the Harveian Society on Jan. 11th Sir William Willcox outlined the modern conception of disease brought about by the discoveries of Pasteur and passed in review the development of medicine and toxicology side by side from the earliest known records in Babylon in 4000 to 3000 B.C. The ancient Egyptians possessed a profound knowledge of drugs and their actions, and they developed elaborate public health measures, even including meat inspection. This knowledge culminated in the Alexandrian School (B.C. 330 to 100). Medicine in Rome, until the influence of the Grecian School of Medicine became felt, was based chiefly on superstition. From this period, through the Middle Ages down almost to Harvey's time, practically no progress was made, medical knowledge remaining at a standstill. From 1615, when the discovery of the circulation of the blood was made, knowledge increased by leaps and bounds, the names of Sydenham, the two Hunters, Jenner, and Laennec were mentioned as landmarks, but it was left to Pasteur to demonstrate the causation of disease and to develop methods of immunity, and to Lord Lister to apply these principles to surgery. The history of toxicology might similarly be traced back to the Egyptians who were certainly familiar with the preparation of hydrocyanic acid from peach leaves and kernels, and with its poisonous properties. The writings of Homer gave a clue to the origin of the word "Toxicology" from τόξον a bow, for Ulysses sought to obtain from Ephyra a poison with which to anoint his arrows. Mithridates, King of Pontus, studied toxicology very deeply, using condemned criminals for experiments. He wrote a book on the subject and invented a universal antidote containing 36 ingredients. Hemlock was used by the Greeks, Socrates dying from its effects. Criminal poisoning was well known in Rome and legislative enactments dealt with this crime and also with the use of poisons to procure abortion. In the Renaissance period poisoning became a fine art, Cæsar Borgia, and Catherine de Medici being well-known exponents. At this period white arsenic and corrosive sublimate were by far the commonest poisons used. Neither medicine nor toxicology made great advance until chemistry and its application in the laboratory to the various problems had sufficiently developed to enable analytical problems to be undertaken. In 1836 the Marsh test was discovered; in 1839 arsenic was detected in all the organs in a case of acute arsenical poisoning by Orfila, and thus the importance of absorption of poisons was for the first time appreciated. In 1844 Fresenius and von Babo devised a method for systematic search for mineral poisons, and in 1850 Stas elaborated a process for the extraction of alkaloidal poisons. With slight modifications these methods stand to-day. Sir William Willcox referred to a number of cases of criminal poisoning, each showing some point of interest in the development of toxicology; among these the trial and conviction of Palmer in 1856 was important, for although the prosecution from clinical and other evidence believed that the victim, Cook, died of strychnine poisoning, this alkaloid was never found in the viscera, and on the evidence a conviction would hardly be obtained to-day. The Lamson case was of interest, for here the poison aconitine was demonstrated by physiological experiment on mice, there being no satisfactory chemical test. Finally, in the Black case in 1922, where the amount of the poison arsenic found was extremely small—less, in fact, than a possible fatal dose—knowledge of the approximate date of the administration and the average rate of excretion made it possible to show that a large dose of arsenic must have been administered.

THE DOCTOR'S TELEPHONE.

THE claim, recently made by Mr. J. M. Keynes, that an etiquette of the telephone should be recognised in order to protect busy men from its too common incivilities, will appeal strongly to medical men. The calling-up of the doctor on the 'phone should be limited to urgent cases. That is the obvious principle, but there are so many degrees of urgency that it would be difficult to lay down any strict rule. The shrewdness and tact of a confidential servant may save his master much time and annoyance, but nowadays many medical men lack this first line of defence. The drawbacks of the telephone as a bearer of important messages are very real. Complaints heard by insurance committees have been known to turn upon a call. Misunderstanding and misinterpretation of doctors' instructions are common, and, apart from the dictaphone, it is not an easy matter to get a correctly transmitted copy of a telephone conversation. We do not know precisely why the doctors of Coalville have decided, as we learn from a Leicestershire correspondent, to give up their 'phones, but the decision was apparently taken on account of unreasonable demands made by patients who were unwilling to write a message or send a messenger. In the case of insurance practice the telephone may lead to fraudulent demands for free treatment from persons who claim to be insured persons, but have no medical card. A contemporary asks: "Is it permissible for a doctor to give up his telephone and tell his patients that they must send for him?" There was a time when a doctor could conduct his practice in any way he chose, provided he observed professional customs and traditions. Recent regulations have altered the position to some extent for insurance practice. Doctors on the panel who live away from their surgeries are required to set up telephonic communication with their private houses so as to be readily accessible out of surgery hours. It seems a short step to the position of requiring the insurance practitioner to provide a telephone at his house. The friendly societies would have it so.

THE death is announced after a long illness, of Mr. H. P. Symonds at Oxford, and of Prof. Johannes Orth, successor of Virchow at the Berlin Pathological Institute.

Sir E. Sharpey Schafer has accepted the invitation to be the first Horsley Memorial lecturer. The lecture will probably be delivered in the autumn.

INDEX TO "THE LANCET," VOL. II., 1922.

THE Index and Title-page to Vol. II., 1922, which was completed with the issue of Dec. 30th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

III.

THE TREATMENT OF NEURALGIAS OF THE HEAD AND NECK.

ONE of the commonest difficulties in practice is the successful treatment of neuralgic pains about the head, and neck, and face. The primary and chief difficulty is the correct diagnosis of the source of the mischief, and it is highly important not to miss the recognition of organic causes of trouble which, by correct early treatment, might be cured, and to avoid the too facile temptation to the busy practitioner to assume a minor ailment and to order aspirin and other analgesics, while hoping for the best.

Dental Neuralgia.

Dental neuralgia is naturally one of the commonest, while one of the most acutely painful forms. Exposed dentine from wearing through the enamel by the hook support of a denture is a not unfrequent source of aching pain, sometimes of so fierce a nature that it has been mistaken for grave trigeminal neuralgia. A carious cavity in a tooth, especially if irritated by sweet food, often causes agonising pain. Before expert dental advice can be obtained in such cases it is a valuable help to be able to relieve the patient's sufferings, which can almost certainly be done in a few moments, after gently cleaning out the tooth cavity, by the application of a wad of cotton-wool steeped in a solution of equal parts of menthol, carbolic acid, and oil of cloves. Indeed, a useful household remedy is a small bottle containing a drachm each of these three ingredients. It is easily applied by twisting a wisp of cotton-wool round the wooden end of a match. Another dental neuralgia more difficult to relieve is an acute infection of the periodontal membrane, in which the tooth as a whole is tender and " stands on end." If no dental assistance is available, it may be possible to arrest the pain by salicyl ionisation of the side of the face. Painting the gum with iodine is commonly ordered for this complaint, but I have never known it do the slightest good. The pain may be so fierce that morphia injection may be necessary, and often nothing short of extraction of the tooth gives relief. In obscure cases of persistent neuralgic pain of the jaws X ray films of the jaws and teeth should be taken, as impacted or unerupted teeth or other gross disease of the bone may thus be demonstrated as the cause.

Antral Abscess.

Antral abscess may usually be demonstrated by X rays or by transillumination, the pain at first limited to the region of the cheek and upper jaw, sometimes over the whole territory of the fifth nerve on that side, and down the neck even into the arm and fingers. A carious last lower molar often gives rise to pain in the ear and neck, the pain, too, being referred even down the arm. It is important to remember that though a dental neuralgia may give rise to pain reflected over other areas on the same side of the face and neck, yet the neuralgia never crosses to the opposite side of the face. Hyperæsthesia of the skin is common in these neuralgias, but if on examination definite anæsthesia of the upper or lower lip or cheek is found, this is at once evidence, in a patient who has never been operated on or injected for the neuralgia, that some gross disease, such as a gumma or a malignant growth, is damaging the fifth nerve or one of its main branches. Syphilitic neuralgias of the fifth nerve are usually very amenable to suitable treatment, but malignant growths of the upper jaw or tonsillar region are extremely difficult to relieve. Occasionally alcohol injection of the Gasserian ganglion may arrest the pain in inoperable growths of the upper jaw or in recurrent epithelioma of the tongue and lower jaw.

Paroxysmal Trigeminal Neuralgia.

True paroxysmal trigeminal neuralgia in its early stages is often difficult to distinguish from some of the local causes of pain already referred to, but the characteristic hot flashes of pain started by movements of the lips or jaws or by light touches on the cheek, especially when the pain has recurred at intervals for months or years, will decide the diagnosis. Treatment by carefully applied salicyl ionisation to the side of the face, using thick pads, sometimes gives great relief; in others the administration of thyroid extract internally, or tincture of gelsemium in full doses with butyl chloral hydrate may arrest the paroxysms. Change of climate is of little value, and in obstinate cases which resist the treatments described recourse should be had to alcohol injection of the nerve trunks or of the Gasserian ganglion before considering the major operation for resection of the sensory root of the fifth nerve within the skull. Repeated injections of morphia and heroin should never be employed, as little relief is obtained, and the habit once established is very difficult to eradicate.

Supra-orbital Neuralgia.

Supra-orbital neuralgia, when not migrainous or due to sinus inflammation, may be a post-febrile perineuritis following influenza, malaria, or even a common cold. There is usually tenderness over the supra-orbital notch, and the pain is often periodic, coming on about 11 A.M. and lasting until 5 P.M. I have, however, seen the same periodicity with pain in the cheek due to antral abscess. Hypodermic injections of morphia given on three successive days an hour before the usual onset of the pain may cure the condition, but sometimes the vomiting induced by the morphia aggravates the pain. Rest and analgesics, such as pyramidon and caffeine, with salicylate of soda, will cure other cases, but in some cases the pain is inveterate and may persist for many years. It may then be relieved by alcohol injection at the supra-orbital notch or by resection of a piece of the nerve itself.

Post-herpetic Frontal Neuralgia.

Post-herpetic frontal neuralgia is occasionally a troublesome sequel of frontal or ophthalmic herpes. Usually the persistent abnormal sensations amount to no more than formication, numbness, and a sense of constriction, but sometimes neuralgic pains are severe. Sedatives as bromide, aspirin, and other analgesics may give some relief, but the condition is difficult to cure, though usually it subsides gradually after a few weeks or months. If the pain is very severe and persistent, it may be advisable to destroy the Gasserian ganglion by alcohol injection or to resect the sensory root.

Migrainous Neuralgia.

Migrainous neuralgia is a form of migraine in which the pain is localised in the temple, or it may spread anteriorly into the upper part of the face. It resembles migraine in its periodicity, and is accompanied by nausea, but is rarely preceded by visual scotomata. The pain is liable to be mistaken for trigeminal neuralgia, but should never be treated by alcohol injection. Aspirin, pyramidon, and similar drugs may relieve, and in obstinate cases luminal in 1 to $1\frac{1}{2}$ gr. every night at bedtime for three weeks, then gradually diminishing the drug to $\frac{1}{2}$ gr. twice a week, may be of the utmost value.

Occipito-nuchal Neuralgia.

Occipito-nuchal neuralgia is sometimes functional in origin, but in others may be a form of infective rheumatism or fibrositis, or secondary to an influenza or nasal catarrh. A vaccine obtained from cultures of nasal discharges or from an infected tonsil or dental sepsis is successful at times, while radiant heat, ionisation, and massage will be sufficient in other cases, with occasional doses of aspirin or the stronger analgesics, but never morphia or heroin.

Psychalgia.

Functional head pains or psychalgias occasionally mimic trigeminal neuralgia somewhat closely, but may always be distinguished if sufficient care is taken. Often the pain is boring or like a heavy weight on the vertex. Operations of all kinds and alcohol injection must be avoided entirely, as the pains are certain to be aggravated and rendered more difficult to cure. Psychotherapy may succeed in eradicating the trouble, and moral treatment in change of scene and occupation is preferable to the use of analgesic drugs.

WILFRED HARRIS, M.D. Camb.,
F.R.C.P. Lond.,
Physician to St. Mary's Hospital and to the Hospital for Epilepsy and Paralysis, Maida Vale.

Special Articles.

THE MEDICAL RESEARCH COUNCIL.

ANNUAL REPORT, 1921–1922.

THE report of the Medical Research Council for the year ending Sept. 30th, 1922, is much more than an account of the manner in which the sum placed at the disposal of the Council for that year has been expended. Since the grants have been distributed with the idea not only of initiating new work but of supplementing the funds already available from other sources where necessary, the report serves as a fair index of the development of medical research work throughout the country. For example, it is explained that if no large place in the schemes of research summarised is given to the investigation of cancer, this is because private endowment and subscription have done much to support investigation in this subject. From the purely financial standpoint the grant-in-aid at the disposal of the Council is only a small contribution from the State which meets and augments provision derived from other sources. The effective value of this public contribution gains from two circumstances. It gains from its mobility—for example, the Council was able to take immediate measures, on the discovery of insulin, to encourage and support at several centres research work designed to expedite its production on a large scale. It is greatly enlarged, too, by this partnership with private effort; without this it could only have supported effectively a far narrower range of research work than that which this report displays.

The General Framework.

The sum provided by Parliament for the expenditure of the Medical Research Council during the year was £130,000; out of this the cost of the work of the Industrial Fatigue Research Board and the grants formerly made for researches into mental disorders and for certain pathological investigations to the Boards of Control for England and Wales and Scotland had to be met. £8000 were provided for administration, £34,000 for the expenses of the National Institute for Medical Research, and £88,000 were allocated to research work in specific subjects by scientific men, to research in clinical medicine, and to the investigations of the Industrial Fatigue Research Board.

The seven sections into which the report is divided are the more readable because the classification of subject matter is not carried out on a rigidly logical plan; overlapping or cross references constantly occur. After an introductory section, the work in progress at the National Institute of Medical Research is outlined. Section III. deals with experimental medicine and the research work of the clinical units in various hospitals, in so far as this is subsidised by the Council. Section IV., on the determination of biological standards and the methods of biological assay and measurement, includes an account of that part of this work which is being undertaken at the National Institute of Medical Research, to which only brief reference had been made in Section II. In Section V. all attempt at topographical division is abandoned, and research in specific subjects is described under the headings of the disease investigated, irrespective of the place where such investigations are carried on. In Sections VI. and VII., researches in industrial medicine and fatigue, recent benefactions to medical research and education are noted, and the report is concluded by a tribute to the late Dr. W. H. R. Rivers. The appendix contains the names of the members of investigation committees for special subjects—elsewhere the gratuitous service on these committees on the part of scientific men receives cordial appreciation—and a complete index of personal names referred to in the report and of institutions where work is being carried on.

Certain general lines of development in the work undertaken are noteworthy. Quarterly conferences between the Council, the Development Commission, the Department of Scientific and Industrial Research, and a representative of the Royal Society, have been arranged, to maintain coöperation between these bodies. The assistance given by the Council, at the request of the Health Section of the League of Nations, to the International Conferences summoned to discuss the international standardisation of biologicals is likely to lead to important results. New weapons for investigating filterable viruses, in the shape of new technical methods, are expected to give a fillip to this work, and within and without the National Institute biochemists, physicists, and pathologists have been enlisted to work in association with investigators at fever hospitals. The difficulty of proceeding by sound experimental methods in dealing with diseases attributed to filterable viruses in human beings has led the Council to make arrangements for an experimental study of distemper in dogs. It seems probable that the infective agent is a filterable virus, and there is ground for hope that the study of dog's distemper under strict experimental conditions may throw important light upon analogous problems of human disease.

National Institute for Medical Research.

The need for field laboratories in close effective touch with the National Institute has recently become urgent. The work on filterable viruses will require facilities for isolation and study of diseased animals which are impossible within the limits of the Institute itself. The Council are thus to be congratulated on their purchase of a small site for field laboratories outside the metropolitan area, within easy reach of Hampstead, where this and other work will be carried out.

Research in the National Institute has been carried on vigorously, with close coöperation between the six departments. We have selected from the urgent activities recorded a few examples typical of the work in progress in each department.

Department of Biochemistry and Pharmacology.—Under the general direction of Dr. H. H. Dale, Dr. Lovatt Evans has done work of fundamental importance on the acid-alkali balance of the blood. Dr. Dale and Dr. C. H. Kellaway have completed and published work on anaphylaxis and anaphylatoxins, while Dr. J. H. Burn has cleared up a puzzling discrepancy between experimental findings and clinical observations on the relation of the sweating produced by pilocarpine to the integrity of the nerve-supply of the sweat glands. Dr. H. W. Dudley's unsuccessful efforts to isolate the active principles of the posterior lobe of the pituitary gland are highly instructive. For example, a crystalline picrate was isolated which, after several recrystallisations, showed an intense action upon uterine muscle. This proved, on ultimate purification, to be an inert substance to which a mere trace of the true active principle had been adherent. It seems clear that principles having an activity of this order will not be directly isolated and identified by methods at present available. Dr. H. King has completed an investigation proving that the previous conceptions of the nature of muscarine were erroneous, since the materials subjected to analysis consisted chiefly of choline contaminated with muscarine.

Department of Experimental Pathology, Bacteriology, and Protistology.—Captain S. R. Douglas, the director, has been engaged on special studies of the cultivation and isolation of the *B. diphtheriæ* for the Bacteriology Committee. For the Committee on the Biological Actions of Light preliminary experiments were made to ascertain if overdoses of light rays tend to allow the tissue of resistant animals to be invaded by bacteria. These experiments were made on rats, and it was found that when tubercle bacilli present in the skin received the application of light from a mercury vapour lamp on a shaved area a progressive lesion was produced in a considerable percentage of the animals, while, in control animals, ordinary regressive lesions commonly seen in the rat were present. Attempts have also been made by Captain Douglas to determine the thermal death-point of tubercle bacilli occurring in naturally infected milk. It appears to be certain that a temperature of 65° C. for 30 minutes will kill the tubercle bacilli in naturally infected cow's milk. Dr. W. E. Gye has, with Dr. W. Purdy, investigated the pharmacology of colloidal silica; and with Dr. E. H. Kettle, of St. Mary's Hospital, he has published studies of the effects of silica dust upon the tissues, with special regard to the problems of industrial tuberculosis, and has begun some special studies of the pathology of general tuberculosis in young people. Dr. P. P. Laidlaw has attempted to define more closely the factors which favour the growth of pathogenic bacteria. Some constituent of uncertain nature, present in meat extract, is strongly stimulating. In the department of protistology, Mr. C. Dobell, in collaboration with Dr. Gye, is studying the microscopic and cytological methods best suited for continuing work on spirochætes, as a preliminary to the resumption of work on the ætiology of disseminated sclerosis.

Department of Applied Physiology.—Dr. Leonard Hill, the director, and Dr. Argyll Campbell have continued investigations into problems of blood heat and metabolism. It was found that balneotherapy at the Hayling Island Colony increased by 100 to 200 per cent. the metabolism of the children who were immersed without muscular movement. It was concluded that open-air treatment, heliotherapy, and balneotherapy might be applied with advantage to cases of illness other than tuberculosis usually involving long confinement in bed. A wind tunnel has been constructed at the Institute, fitted at one end with a suitable fan so that a wide variation of cooling powers can be obtained within the tunnel. At the other end a walking platform, electrically revolved, has been inserted in the floor; on this, walking or running can be undertaken by the subject, almost stationary in relation to the walls and the observer, and cooling can be effected as desired. The amount of cooling necessary for comfort during various degrees of muscular work can thus be calculated.

Department of Applied Optics.—The studies of Mr. J. E. Barnard, the honorary director of this department, for the improvement of microscopical methods has been continued. With a view to reducing certain instrumental difficulties met with, a new type of illuminant, a new form of microscope, and certain improved optical parts have been evolved and have proved of much service. A simple and inexpensive appliance has been devised for the easy identification of the spirochæte of syphilis, by which the number of convolutions in the spirochæte can be quickly determined in reference to the diameter of a red blood cell. In view of the common want of agreement between the micrometric results obtained by different workers describing the same structures, an apparatus has been installed to which any worker in the Institute can refer, constancy and accuracy being thus assured. In collaboration with Captain Douglas, the structure of bacteria seen as the result of staining has been carefully compared with photographs taken of living organisms by means of ultra-violet light. The results are interesting and suggestive, as showing the changes that are due to the processes incidental to staining. Studies of the use of ultra-violet light in microscopy have been continued with encouraging results. Shorter wave lengths are being used and the results indicate that structures of a smaller order will be resoluble.

Department of Statistics.—Among the investigations in progress in this department is one undertaken on the incidence of cancer in different trades, from statistics placed at the disposal of the Council by the Registrar-General. The data refer to 46,235 deaths among males, both occupied and retired, occurring in over 900 trades and professions in England and Wales during the period 1910–12. This material is to be examined and reported on by Dr. J. Brownlee in collaboration with Prof. E. L. Collis, of the Welsh National Medical School.

Library and Publications Department.—The Council again draw attention to the fact that approved persons are allowed free use of the library, and that assistance is offered to those working on the Council's behalf in the verification of references and in the supply of information.

Standardisation of Biologicals.

Work directed to the determination of biological standards, and of methods of biological assay and measurement, for substances of which the physiological effects cannot be quantitatively estimated by direct chemical means, continues. Another branch of work is the standardisation of pathological methods with a view to uniformity of results: this includes both the maintenance of central sources for the supply of standard types of micro-organisms and of standard sera, and the devising of serological and other methods for general acceptance.

In standardising tests for arsenobenzol compounds it has been found that the curative powers of arsenobenzol substances, as tested on trypanosomiasis in mice, could be adopted as an index of their therapeutic value in human syphilis. A trustworthy standard of reference for pituitary extract has been elaborated by Dr. Dale and Dr. Burn, whereas in the hands of Dr. P. Hartley, the dried sample of antidiphtheritic serum, which is contemplated as the standard of antitoxin for this country, should be ready for issue in the early future.

The national collection of type cultures at the Lister Institute, under the direction of Prof. J. Ledingham, has made steady progress. Over 300 fresh types were received, and over 2500 cultures were distributed. It is of interest to learn that the cultivation of *B. tularense* has proved so dangerous to laboratory workers in this country and in America that it has been deemed inadvisable to continue its propagation in the National Collection. The work of the Standards Laboratory at Oxford has been maintained by Dr. A. D. Gardner, under the general direction of Prof. G. Dreyer. A comparative trial of the Sigma and Wassermann reactions in 1000 specimens of blood from syphilitic patients and controls has been made, and a further series of tests, including the Sachs-Georgi and Meinicke III, is in progress.

Research Subsidised by the Council in Various Centres.

In the Council's department of Clinical Research and the cardiographic department of University College Hospital Medical School, under the direction of Sir Thomas Lewis, experimental investigations have made possible a very complete conception of the action of quinidine in fibrillation of the auricles, and have explained the instances not only of successful but also of unsuccessful treatment. The subdivision of patients into groups before treatment with quinidine, according to whether success may be expected or not, is being attempted, and the after-history of successfully treated cases is being followed up. The comparative merits of quinidine and digitalis in the treatment of clinical cases is also being investigated at the London Hospital by Dr. A. M. W. Ellis and Dr. A. E. Clark-Kennedy. At St. Bartholomew's Hospital Dr. G. K. Stone, in association with Mr. D. P. Dunhill, is endeavouring to ascertain whether in Graves's disease the thyroid yields a secretion differing qualitatively from the normal; at the University of Sheffield the dietetic factors causing abnormal developments of the thyroid gland are being studied by Prof. E. Mellanby, while at the Royal Free Hospital Dr. G. S. Williamson is working at its pathology. At St. Mary's Hospital Sir Almroth Wright has been actively continuing his studies of immunisation with the assistance of Dr. L. Colebrook, temporarily seconded from the National Institute. The chief research supported at St. Thomas's Hospital by the Council during the year was that on renal disorders and function tests, carried out by a group of workers mainly under the direction of Prof. H. Maclean. Prof. J. Shaw, Dunn, at the University of Birmingham, and Dr. A. S. Strachan, at the University of Glasgow, are conducting work on experimental nephritis. At the Royal Infirmary, Edinburgh, by Dr. H. W. Davies and Mr. C. R. Harrington, under Prof. J. C. Meakins, disorders of the respiratory system have been the subject of special study, while the mechanism of respiration has occupied the attention of Sir J. Charlton Briscoe at King's College Hospital. A long series of clinical observations are being made at Guy's Hospital, with a large oxygen chamber, on the effects of oxygen administration. The data already collected indicate that patients suffering primarily from damage to the lung receive benefit from treatment with oxygen, but not those with circulatory disorders. Research work in clinical medicine is being carried on in various centres, notably at Norwich, Hull, Glasgow, Newcastle, and London, by Dr. H. J. Starling, Dr. E. E. Laslett, Dr. Ivy Mackenzie, Dr. D. K. Adams, Dr. W. E. Hume, Dr. L. S. T. Burrell, Dr. G. Bourne, and Dr. P. Hamill.

The financial support given to the St. Andrews Institute of Clinical Research has been increased. As part of an organised scheme for research on the problems of child-life, the factors contributing to dead births and premature births are being investigated by competent observers, including clinicians, pathologists, and physiologists in many centres throughout the country. Other problems connected with pre-natal influence being actively attacked are the toxæmias of pregnancy, metabolism, and general physiology in pregnancy and the lying-in period, and the influence of maternal nutrition on the infant. Post-natal studies include metabolism in infants and the influence of various factors on nutrition and growth. In this respect the attempt to obtain information at welfare centres, in spite of the cordial efforts to help made by the various officials, is said to have been disappointing. This is partly because the workers have not been trained to keep accurate records, and partly because the centres are congested. From an analysis of the comparatively small number of figures now available no correlation is manifest between the nutrition of the child under one year and the size of the family, position of the child in the family, or number of persons per room. On the other hand, there appears to be an indication of a direct correlation between the condition of the child and the health of the mother during pregnancy.

Work on rickets has been subsidised in Glasgow, Leeds, and various other centres. In Sheffield the experimental work in the recently established field laboratories is brought into close relation with clinical work in the Royal Infirmary. Closely associated with these endeavours to clear up the ætiology of rickets are the observations on the nature of the substance or substances giving its valuable therapeutic qualities to cod-liver oil, in connexion with which expeditions to Norway and Newfoundland were undertaken by Prof. J. C. Drummond and Dr. S. S. Zilva. Studies in deficiency diseases in Central Europe by Dr. Harriette Chick and her fellow-workers confirm many important researches made in England and America, and may serve to reconcile the hitherto apparently opposed points of view upheld respectively by the adherents of the hygienic and dietetic theories of rickets. Research in neurology aad psycho-pathology includes work on disseminated sclerosis, neuro-syphilis, and lethargic encephalitis, while Miss L. G. Fildes, at the University of Cambridge, is endeavouring to discover what specific psychological characteristics, if any, exist which mark off a mentally defective from a mentally normal individual. Valuable research work at the Lancashire County Asylum, the Maudsley Hospital, the Cardiff City Mental Hospital, and at the Scottish Western Asylum's Research Institute, Glasgow, and the Scottish Asylum's Pathological Laboratory, Larbert, is also in progress.

An Appreciation.

The foregoing examples must serve as an indication of the wide range in geographical situation, in personnel, and in the pathological conditions selected for investigation of the work being subsidised by the Medical Research Council. No less important than those mentioned are many other investigations being conducted in other branches of biochemistry, physiology, and pathology. For details of current work on tuberculosis, influenza, rheumatic fever, diphtheria, venereal diseases, arthritis, malignant disease, radiotherapy, epidemiology, and many other subjects we must refer readers to the report and to the published work referred to therein. In this connexion we would congratulate those responsible for its preparation on the reticence which they have observed as to the details of work still unpublished, except when it is actually in the press, while indicating the broad lines to which it is directed. Preliminary communications are recognised as unfair to authors and to the public, especially in a document designed for all sections of the community; but a report dealing solely with work already published, from which some of the glamour must already have departed, would make dull reading. The discrimination which combines brief summaries of the work completed in the period under review, with inspired comment on present activities, makes these annual reports issued by the Medical Research Council documents which are keenly anticipated from year to year as a living history of the developments, occasional disappointments, and brilliant successes of modern medical research.

DANGEROUS DRUGS ACT, 1920.

POSITION OF DOCTORS AND DENTISTS UNDER THE ACT.

BY the Dangerous Drugs Act and the regulations made under it certain obligations in regard to the giving of prescriptions and keeping of records devolve on medical and dental practitioners, and the Home Secretary, with whose department rests the general responsibility for the administration of the Act and regulations, has had under consideration the best means of carrying out such inspection as may be necessary from time to time to ensure the due fulfilment of those obligations. He has come to the conclusion that such inspection would be best carried out by medical officers, and after consultation with the Minister of Health and the Scottish Board of Health it has been arranged that as a general rule this work shall be carried out in England and Wales by medical officers of the Ministry of Health, and in Scotland by medical officers of the Scottish Board of Health.

It is considered that it may be convenient for doctors and dentists to have a short statement of the main provisions of the Act and regulations in which they are specially concerned.

1. *General Provisions.*

(*a*) *Substances Involved.*—The substances to which the Dangerous Drugs Act applies are:—Raw opium and medicinal opium; cocaine and ecgonine and their salts; morphine and its salts; diamorphine (heroin) and its salts, and any preparation, admixture, extract or other substance containing one-fifth per cent. or more of morphine or one-tenth per cent. or more of cocaine, ecgonine, or diamorphine. (The above are collectively referred to as dangerous drugs.) The percentage in the case of morphine is calculated as in respect of anhydrous morphine.

No person is allowed to bring into, or take out of the country any of the drugs unless he is licensed by the Home Secretary, and no person is allowed to be in possession of the drugs (subject to the exceptions named in the next paragraph) unless he is licensed or otherwise authorised for the purpose, or unless the drug has been supplied for his use by a medical practitioner or in accordance with a medical or dental prescription.

(*b*) *Preparations Excepted.*—It should be noted that the following preparations, though they come within the Act, are specially exempted from the regulations, and may be bought and sold in this country in the same way as ordinary "poisons" under the Poisons and Pharmacy Act :—

Cereoli iodoformi et morphinæ, B.P.C. ; emp. opii, B.P. 1898 ; lin. opii, B.P. ; lin. opii ammon., B.P.C. ; pasta arsenicalis, B.P.C. ; pil. hydrarg. c. opio, B.P.C. ; pil. ipec. c. scilla, B.P. ; pil. plumbi c. opio, B.P. ; pil. digit. et opii co., B.P.C. ; pil. hydrarg. c. creta et opii, B.P.C. ; pulv. cretæ aromat. c. opio, B.P. ; pulv. ipecac co., B.P. (Dover's Powder) ; pulv. kino co., B.P. ; suppos. plumbi co., B.P. ; tablettæ plumbi. c. opio, B.P.C. ; ung. gallæ c. opio, B.P. ; ung. gallæ co., B.P.C.

It should also be noted that the following preparations do not come within the Dangerous Drugs Act :—

Any preparation containing less than one-fifth per cent. of morphine or one-tenth per cent. of cocaine, ecgonine, or heroin. Thus any mixture containing in each drachm not more than 11 minims of tr. opii or 13 minims of liquor morphinæ hydrochlor., and 15 minims of liquor morphinæ acetat. would be unaffected by any of the provisions of the regulations.

(*c*) *Medical Practitioners and Dentists are Authorised Persons.*—Any duly qualified medical practitioner and any registered dentist is authorised by the regulations to be in possession of, and to supply, dangerous drugs, and (in the case of medical practitioners only) raw opium, *so far as it is necessary for the practice of his profession.* The words in italics are important : a doctor or dentist may not have or use the drugs for any other purpose than that of ministering to the strictly medical, or dental, needs of his patients.

Subsequently throughout this Memorandum "doctor" is to be read as meaning a medical practitioner whose name is on the Medical Register ; and "dentist" as a dental practitioner whose name is on the Dental Register.

In what follows it should be noted that Part 2 applies to all practising doctors and dentists ; Part 3 to those only that dispense.

2. *Regulations Applicable to All Doctors.*

(*a*) *Prescriptions.*—The following remarks only apply to prescriptions for medicines containing a dangerous drug in sufficient strength to come within the Act (see above).

The Home Secretary has power to prescribe an official form to be used for such prescriptions, but he has not at present done so.

Under the regulations the prescription—

(1) Must be in writing and be dated.

(2) Must be signed with the *full name* of the prescribing doctor or dentist (the Christian names as well as the surname must be written in full ; initials do not satisfy the regulations.[1])

(3) Must bear the *address* of the prescribing doctor or dentist (except in the case of prescriptions issued for National Health Insurance purposes on the official form).

(4) Must state the name and address of the patient (a prescription may not be given for the use of the prescriber himself).

(5) Must state the total amount of the drug to be supplied on the prescription.

Dentists may give prescriptions for dental treatment only, and in addition to complying with the above requirements they must mark the prescription "for local dental treatment only."

The prescription has to be retained by the chemist by whom it is dispensed (except in the case of prescriptions issued for National Health Insurance purposes on the official form), and he is only allowed to dispense it once, unless the doctor or dentist specially directs in the prescription that it may be dispensed twice or three times (but not more than three times), at intervals which he specifies. In no case is the chemist allowed to dispense it more than three times.

A doctor or dentist who gives, and a chemist who accepts and dispenses, a prescription not drawn up in every particular in accordance with these regulations, commits an offence against the Act.

The Home Secretary desires to impress as strongly as possible on doctors and dentists the importance of their observing these requirements strictly when giving a prescription. Any irregularity on the part of the doctor or dentist may lead to delay in the patient obtaining the medicine prescribed for him—and it is extremely unfair to the chemist that he should be placed in the position of delaying an important prescription, and possibly offending the doctor or dentist, or committing a breach of the law. The Secretary of State has reason to believe that at the present time there are very numerous irregularities in giving prescriptions for the drugs, and representations have been made to him by chemists as to the difficult position in which they are placed, and, he is afraid he must add, the annoyance or resentment displayed by doctors and dentists in many cases at being asked to correct the irregularities of their prescriptions.

(*b*) *Method of Obtaining Supplies of the Drugs.*—A doctor or dentist who requires the drugs for the purpose of his practice may obtain them from any person who has a general licence or authority under the Dangerous Drugs Act to supply the drugs. All pharmacists who are lawfully keeping open shop in accordance with the provisions of the Pharmacy Acts are so authorised (except in the rare cases where the authorisation has had to be withdrawn for offences against the regulations), and all, or practically all, the established firms of wholesale chemists have also obtained licences from the Home Secretary to supply the drugs. In any case of doubt, a doctor or dentist can always ascertain, by inquiry from the Home Office, whether a firm is authorised to supply the drugs or not.

It will assist the administration of the law, and probably also save the doctor or dentist some inconvenience, if he gives all orders for the drugs in writing (except in cases of extreme emergency), and signs them with his full name and address. The chemist has to satisfy himself before selling the drugs that the purchaser is authorised by the regulations to have them, and in cases where the doctor or dentist is not well known to him some delay in making inquiries may be avoided by a full written order, duly signed.

If a messenger is sent by the doctor or dentist to take delivery of the drugs, the messenger must be given an authority in writing, signed by the doctor or dentist, to receive the drugs on behalf of the doctor or dentist : a chemist is forbidden to deliver drugs to a messenger not so authorised.

A doctor or dentist is not allowed to be supplied with the drugs on a prescription made out by himself in his own favour.

Doctors and dentists are advised to keep any dangerous drugs, when not in use, under lock and key, so far as possible. This is not actually required by the regulations, but is obviously a desirable precaution.

A doctor or dentist who requires the drugs solely for administration to his patients by himself personally, or under his own direct personal supervision, and does not dispense them, is under no obligation to keep the records required by the regulations as explained in Part 3 of this Memorandum.

3. *Regulations Applicable to Dispensing Doctors.*

Doctors who dispense or supply medicine[2] are under the obligation to keep the registers of purchases and supplies described below.

(*a*) *Register of Purchases.*—Separate registers or separate parts of a register are to be appropriated for each of the drugs. The tabular form in which the register has to be kept has the following headings :—

(1) Date on which supply received.
(2) Name of person, body, or firm from whom obtained.
(3) Address of person, body, or firm from whom obtained.
(4) Amount obtained.
(5) Form in which obtained.

The correct entry in the register must be made on the day on which the drug is received or the following day : and entry must not be cancelled, obliterated or altered—any mistake must be corrected by a footnote or marginal note, giving the correct particulars, and dated.

(*b*) *Register of Supplies.*—Similar registers or parts of a register must be kept for each drug "supplied" in the tabular form, with headings as follows :—

(1) Date of supply.
(2) Name of person to whom supplied.
(3) Address of person to whom supplied.
(4) Authority of person, body, or firm to be in possession of the drug.*
(5) Amount supplied.
(6) Form in which supplied.
(7) Specify the ingredients of the prescription.

* Where, as will usually be the case, the supply is on the doctor's own prescription, it will be sufficient to enter the word "Patient" in this column.

The entry must be made on the day on which the drug is supplied, or the following day. The same rules as to mistakes and corrections apply.

N.B.—It is specially provided, however, by the regulations, that if a doctor keeps a day-book in which he records particulars of any of the drugs dispensed by him to his patients, with the name and address of the patient and date of supply, he need only record in his register of supplies the date and the appropriate reference to the entry in his day-book.

---

[1] It is proposed in the case of prescriptions issued for National Health Insurance purposes on the official form to require only the surname in full, with the initials of the Christian names.

[2] The obligation would apply in the case of a doctor or dentist leaving a supply of any of the drugs with a nurse for administration to a patient during the absence of the doctor or dentist.

A doctor who dispenses at more than one set of premises is required to keep a separate register or registers at each set of premises.

All records, including registers, day-books, and other documents, must be kept for not less than two years from the date of the document or the last entry therein.

4. *Offences and Penalties.*

A doctor or dentist who obtains, or attempts to obtain, the drugs for a purpose not covered by his authorisation, or who infringes any of the regulations, commits an offence against the Act, and, if convicted, is liable to a fine of £200, or to imprisonment, with or without hard labour, for six months, or to both fine and imprisonment.

Further, the Home Secretary has power, after the conviction of any doctor or dentist, to withdraw from him his authorisation; the effect of this would be to deprive him entirely of the right to be in possession of or to supply the drugs.

5. *Hospitals, &c.*

Hospitals, asylums, Poor-law institutions, or sanatoriums supported by a public authority or out of public funds or by a charity or voluntary subscriptions, have been exempted by Home Office Order from the operation of the Dangerous Drugs Regulations, subject to compliance with the conditions laid down in the Order. The terms of the Order (dated August 15th, 1921, and to be obtained from the Stationery Office) should be consulted.

6. *Inspection.*

All registers and other records required to be kept for the purposes of the Dangerous Drugs Act and Regulations thereunder, and any stocks of the drugs held, must at all times be available for inspection by any duly authorised inspector. As indicated in the opening paragraph of this memorandum, the Home Secretary has authorised medical officers of the Ministry of Health and of the Scottish Board of Health to act as inspectors for this purpose in England and Wales and in Scotland respectively.

Notice of a visit for the purposes of inspection will not necessarily be given, and medical practitioners who dispense should make such arrangements that the registers and other records can be produced, if required, for inspection in their absence.

This memorandum will be printed in pamphlet form, and will be put on sale by the Stationery Office.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Medical Fees.

IN Germany the Medical Practice Act rules that fees are subject to arrangement between the medical man and his patient. Only in cases where nothing has been agreed upon is the Government legally authorised to fix the charges. In the majority of the Federal States an official regulation does indeed exist. The oldest regulation in this connexion was made in 1815, and although its items had long lost their meaning it was actually in force until altered in 1895. Other alterations were made in 1920 and in 1922, the latter providing for Government alteration of fees according to the value of the currency, at first every three months, and lately even every month. Additional payment was sanctioned, first of 50 per cent., then of 200 per cent., and in December, 1922, actually of 900 per cent. of the original official fee. The regulations provide for maximum and minimum fees graded according to the gravity of the case and the financial position of the patient; the minimum fee is to be paid only when the bill is met out of public or charity funds or by sick clubs. In certain country districts medical fees are graded in accordance with the price of bread; in Nassau, for instance, the price of a consultation was before the war 1 mark—the equivalent of two 4-lb. loaves of bread. Owing to the general poverty the fee is now reduced by half. One loaf now costs 500 marks; this sum is, therefore, at present charged for a consultation, and 1000 marks are charged for a visit. In Berlin the Medical Chamber (see below) has advised members of the profession to charge 500 times the pre-war fees, which for a consultation ranged between 2 and 10 marks; the minimum fee for a consultation is now 1000 marks, and for a visit upwards from 1500 marks. A tariff is posted in the doctor's waiting-room, so that patients know exactly what they have to pay. These fees are valid only for Germans and for foreigners who live in Germany and receive their wages in German currency. Foreign tourists and business men have to pay the fees current in their countries, the Medical Chamber having made an inquiry as to the fees customary in most of the principal countries. The last number of the *Berliner Aerztekorrespondenz*, the official organ of the medical chamber, contains the fees for England, Holland, Italy, Denmark, Jugo-Slavia, Norway, and Czecho-Slovakia. The lists contain the fees for general practitioners, for specialists, and for hospital physicians and surgeons, according to the financial standing of the patient. The English fee for a consultation is set at from 2*s.* 6*d.* to 5*s.*, and so on. The present value (Jan. 5th) of the pound sterling in Germany is 32,000 marks.

Medical Study and Examinations.

A commission, composed of representatives of the Federal Governments, the universities, and the medical profession, is to meet in Berlin, under the chairmanship of the Minister of the Interior, to consider reforms in medical study and examinations. The medical course has hitherto occupied five years; at the end of the second year a first examination takes place, the subjects being natural science, physics, chemistry, anatomy, and physiology. No medical student who does not pass that examination is admitted to the second or clinical part of the course. After a further three years the final examination is taken in clinical medicine, surgery, obstetrics, hygiene, and some special branches of medicine. The student has then to pass through the so-called "practical year" as a sub-assistant in a recognised hospital, after which he becomes qualified, and may settle anywhere in Germany. The principal drawback of the present system of medical study is that it is much too theoretical. Clinical training, for instance, is usually carried out as follows: During a clinical lecture a student is called upon to examine a patient under the professor's supervision, and in the large universities this may happen only a few times each term. In the smaller universities, where there are fewer students, only a restricted number of beds is at the disposal of the students. It must be remembered that only the university clinics are used for the training of medical students; the great hospitals, with numerous patients and well-equipped laboratories, have no connexion with the universities. Before the war a tentative arrangement was made by which large hospitals should place their wards at the disposal of medical students, and this system was first started in Düsseldorf; there a so-called medical academy was founded, originally intended for post-graduate study, but later affording facilities for students to obtain one or two terms of clinical training. But a medical student has generally had little opportunity to examine large numbers of patients himself or to follow up a case—except when he acts as a "famulus"—a voluntary clinical clerk or dresser. In fact, the majority of students receive no practical training before the "practical year" which follows the passing of the final examination. Thus, the clinical training is quite inadequate; moreover, the practical year is itself not always satisfactory, as candidates often go to small hospitals in little towns where they are either insufficiently supervised or are employed as assistants in order to save expense, to the detriment of the patients and of the qualified medical man who has a better claim to such an appointment. The practical year comes too late to secure to the student an adequate clinical training, and it is therefore proposed that one term in the midst of the course should be spent exclusively in hospital work without lectures. The office of famulus would then become compulsory; the medical course would last six years, the practical year after examination would be abolished, and the qualification given immediately after examination at the end of the sixth year. The present examination is spread over two to three months, but Prof. His, who before being called to Berlin was professor at the University of Basle, suggests that a time of two to three weeks would be sufficient, as proved by experience in Switzerland.

Organisation of the Medical Profession in Germany.

The Medical Chamber (Aerztekammer) mentioned above is a body officially representing the medical profession of a province, as the Chamber of Commerce represents the merchants, and the Lawyers' Chamber (Anwaltskammer) the advocates. Each province has its medical chamber, so that there are in Prussia 11 of these chambers, Berlin and the province of Brandenburg having one chamber between them. The chambers are elected every three years by the votes of the medical men of the individual province. They meet two or three times a year; current business is dealt with by a permanent committee elected by the chamber. A joint body composed of representatives of individual chambers meets to discuss matters affecting the general interests of the profession. Before proposing laws affecting medical interests the Government usually consults the opinion of the chambers or of the joint committee. A representative of a provincial administration, or of the central Government, may attend the meetings and give information on behalf of, and answer questions put to, the Government. The medical chambers are entitled to raise, from every registered medical man, taxes which are just as compulsory as the national income tax. The annual budget of a medical chamber must be discussed and passed by the chamber at their first meeting in the year. Apart from the expenses of the chamber, the money is spent for the support of widows and children of deceased members of the profession, and for other purposes connected with professional interests—e.g., post-graduate study. The medical chambers may also pass certain by-laws for the medical profession. The Berlin Medical Chamber has established in its district a so-called Contract Commission (Vertragscommission), and has enacted that every contract between a medical man and a sick club or insurance company must be agreed to by the commission before coming into force.

Medical Courts of Honour.

Every medical chamber appoints a Court of Honour of five members, who have authority to punish offences against the generally-adopted medical rules and etiquette, such as public advertisement, connexion with a quack, and the like. A Court of Honour has the right to summon a medical man and, after legal proceedings, to punish him with a reprimand and a fine; the court has, however, no power, like that of the General Medical Council in Great Britain, to erase names from the Medical Register. No German authority can so erase a name, except in cases where medical diplomas have been obtained by fraud. In the proceedings of the Courts of Honour a representative of the Government acts as public prosecutor, whilst the defendant is entitled to legal assistance or to that of another medical man. Courts of Honour may also arbitrate in disputes arising between medical men. In a committee of the Prussian Diet, Dr. Weyl, a medical member of the House belonging to the Socialist Party, recently moved that Medical Courts of Honour should be altogether abolished. In the discussion which followed some members spoke against abolition, and the motion was rejected with 11 against 8 votes. A motion requiring a reform of the procedure, with provision of facilities for appeal against decisions of the courts, was then passed, together with a recommendation that the Government be requested to arrange for an inquiry among the medical profession as to the advisability of the further existence of these courts.

The Services.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. H. Simson retires on ret. pay and is granted the rank of Col.

Maj. J. W. S. Seccombe, from the half-pay list, is restd. to the estabt.

Capt. S. D. Large retires, receiving a gratuity, and is granted the rank of Lt.-Col.

Capt. A. G. Stevenson retires, receiving a gratuity.

Capt. H. S. Milne relinquishes the temp. rank of Maj. on ceasing to be spec. empld.

The undermentioned Capts. relinquish their commns.: J. C. Brash (granted the rank of Maj.), W. J. Dowling, on account of ill-health (retains the rank of Capt.).

ARMY RESERVE OF OFFICERS.

Army Dental Corps.

Capt. W. H. Donald, late Spec. List, to be Capt.

TERRITORIAL ARMY.

Capt. H. M. Holt (late R.A.M.C., Spec. Res.) to be Capt.

Capt. W. F. Denning (late 4th Bn., Duke of Wellington's Regt.) to be Capt.

The undermentioned relinquish their commns. and retain their rank except where otherwise stated: Lt.-Col. A. R. Tweedie (granted the rank of Col.); Majs. F. B. Treves (granted the rank of Lt.-Col.), P. Moxey (granted the rank of Lt.-Col.), and C. E. Silvester; Capts. P. S. Martin (granted the rank of Maj.), F. L. Newton, D. W. G. Griffith, J. McG. H. Reid, J. R. Herbertson, H. J. B. Fry, C. H. Crawshaw (granted the rank of Maj.), W. O'Brien, and J. M. Mitchell.

Lt.-Col. A. B. Lyon having attained the age limit is retired, and retains the rank of Lt.-Col.

Maj. W. Duncan resigns his commn. and is granted the rank of Lt.-Col.

General Hospitals: The undermentioned having attained the age limit are retired, and retain their rank except where otherwise stated: Lt.-Cols. Sir W. H. White (Bt. Col.), C. W. M. Moullin (Bt. Col.), R. J. W. Oswald, W. H. Battle, Sir D'Arcy Power, F. Warner, and J. Calvert; Majs. W. McA. Eccles (Bt. Lt.-Col), T. D. Acland (Bt. Lt.-Col.) (granted the rank of Lt.-Col.), C. H. Fagge (Bt. Lt.-Col.) (granted the rank of Lt.-Col.), Sir F. W. Andrewes, H. M. Fletcher, L. B. Rawling, Sir P. Horton-Smith-Hartley, F. J. Steward (granted the rank of Lt.-Col.), J. Hutchinson, G. N. Pitt, and W. W. Griffin; Capts. Sir H. M. Rigby (Bt. Lt.-Col.) (granted the rank of Col.), E. H. Fenwick (Bt. Maj.) (granted the rank of Lt.-Col.), H. H. Taylor (Bt. Maj.), Sir W. A. Lane (granted the rank of Col.), J. C. W. Graham (granted the rank of Maj.), R. Whittington (granted the rank of Maj.), W. R. Wood (granted the rank of Maj.), J. H. Thursfield (granted the rank of Maj.), J. Shardlow, M. N. J. Rigby, L. A. Parry, H. Williamson, Sir T. J. Horder, F. A. Rose, C. E. West, W. D. Harmer, J. J. Perkins, W. J. Hadley, H. N. Fletcher, F. A. S. Hutchinson, A. M. Daldy, H. Gervis, G. Morgan, A. M. Colcutt, A. J. Hutchison, C. N. Chadborn, A. G. Bate, C. H. Bryant, W. L. Brown, H. E. G. Boyle, and C. M. H. Howell.

Capts. E. C. Hughes and J. F. Trewby relinquish their commns. and retain their rank.

Capts. H. D. Clementi-Smith and H. W. Wilson relinquish their commns. and are granted the rank of Maj.

Sanitary Companies: Capt. F. T. H. Wood relinquishes his commn.

Capt. W. H. Davison relinquishes his commn. and is granted the rank of Maj.

Supernumerary for Service with the O.T.C.: H. H. Woollard (late Australian Army Medical Corps) to be Capt. for service with the Univ. of Lond. O.T.C.

TERRITORIAL ARMY RESERVE.

Cols. Sir C. J. Symonds and H. H. Tooth having attained the age limit are retired, and retain the rank of Col.

Capt. J. H. Paul relinquishes his commn. and retains the rank of Capt.

Capt. E. D. Ellis, from General List, to be Capt.

General Hospitals: Capt. D. Mallam, from 1st E. Genl. Hosptl., to be Capt. Capt. B. H. Nicholson having attained the age limit is retired, and retains the rank of Capt.

TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon the undermentioned officers: Majs. H. A. Ahrens, R. Y. Anderson, E. H. Brunt, W. F. Munro, and H. B. Low.

INDIAN MEDICAL SERVICE.

Lt.-Col. H. J. K. Bamfield to be Col.

The King has approved the relinquishment of the temporary rank of Capt. Nagendra Narain Majumdar and the retirement of Maj. A. C. Ingram.

Correspondence.

"Audi alteram partem."

REST AND EXERCISE IN PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—Dr. Claude Lillingston's remarks in your issue of Jan. 13th, daring in these days and in this country, on the subject of rest and exercise in pulmonary tuberculosis, deserve the public support of such as are in agreement with them. I am myself one of these, and have already expressed similar views on the importance of prolonged rest in active disease, and the "cure-in-three months" fallacy, in an article now awaiting publication in THE LANCET. The question of "graduated exercise" or "graduated labour" I omitted from that publication save by implication, and it is this omission which tempts me to supply the present letter in support of Dr. Lillingston's condemnation of graduated labour as an end in itself, and applied, as commonly happens, to cases still in various degrees active. "Tolerance" to autotuberculin, the achievement of graduated exercise, has admittedly its own proper uses, and in certain cases of slight disease may probably be induced early without harm, and certainly with great convenience. But, these apart, it seems to me that graduated exercise as usually applied (that is to cases recently febrile) is based on a triad of fallacies.

1. The idea that "tolerance" is, or carries with it, a "high tide of immunity" (Paterson) other than that "high tide" which belongs to every "immune response," and which is presumably just as efficacious in a bed-patient without "tolerance," as after a day's work on grade VI. of "graduated labour." Where, I would ask, is the evidence to support this idea?

2. The impression that because "tolerance" saves from harmful "reactions," therefore active disease is unaffected by exercising the lung. This fallacy I have tried to dispose of in my article already referred to on the importance of rest.

3. The impression, present in many minds, that "tolerance" implies arrest of disease, which is very far from the truth.

The physical exertions which these ideas encourage are, in my opinion, responsible in many cases for needless spread of disease. The decision as to activity and seriousness of disease should not be allowed to rest on a temperature chart or other evidences of autoinoculation alone—the physical condition of the lung must also be taken into account! I remember myself passing through a phase of inexperience when I was doubtful whether "tolerance" might imply absence of activity, but experience soon resolved this doubt, and I now know with many others that "tolerance" and "activity" are not incompatible.

I am, Sir, yours faithfully,
CLIVE RIVIERE.

Queen Anne-street, W., Jan. 15th, 1923.

TREATMENT OF EARLY PULMONARY TUBERCULOSIS IN THE YOUNG ADULT.

To the Editor of THE LANCET.

SIR,—It was with great satisfaction that I read Dr. C. Lillingston's article in THE LANCET last week. The expression of these views in an authoritative journal is some consolation to one who has been preaching almost identical opinions for the last 14 years. There is one observation I should like to add, and that is the necessity of diagnosing early pulmonary tuberculosis from a consideration of symptoms.

With regard to treatment by colloid of calcium I may say that when an article by me was published in January, 1922, in the *British Medical Journal* the benefit of this treatment had practically ceased to be conjectural, and might have been said to have been established so far as this sanatorium was concerned, but, of course, it will not cure all cases. Since then colloid of calcium has proved to be a most valuable therapeutic agent in many hands. It does not operate by suggestion, except in so far as any remedy which does good will add to the feeling of hopefulness, but is a material agent acting similarly to such a drug as iodide of potassium in specific disease. Anyone who read Dr. T. C. Graves's article in THE LANCET of Nov. 4th, 1922, must have been struck by the benefit produced by this agent on individuals who might be said to have no minds. If this chemical substance be given carefully and perseveringly its usefulness cannot fail to be appreciated both in tuberculosis and many other conditions of sepsis.

I am, Sir, yours faithfully,
New Cumnock, Jan. 13th, 1923. EDWARD E. PREST.

EMETINE BISMUTHOUS IODIDE IN THE TREATMENT OF AMŒBIASIS.

To the Editor of THE LANCET.

SIR,—Major Manson Rennie's paper on the value of emetine bismuthous iodide (E.B.I.) in the treatment of amœbiasis published in THE LANCET of Dec. 30th, 1922, is very timely, and it is particularly welcome coming as it does with authority from the Hospital for Tropical Diseases. I have been greatly perplexed during the last three years by the increasing number of people who tell me that emetine in whatever form it is given is "no good" in the treatment of amœbic dysentery. I have heard this opinion stated by a variety of people including physicians on the staff of teaching hospitals and men back from military service in the East. Looking at it from the patient's point of view I have been not merely perplexed but worried, as the only alternative treatment that has been suggested to me—e.g., opium, rectal wash-outs, and vaccines of some coliform organism—seems to be about as useful as aspirin might be for a patient with an intracranial gumma. My own experience of the treatment of amœbiasis is naturally small, but such as it is it tends to confirm Major Rennie's conclusions; and I cannot help feeling that a good deal of the disrepute into which E.B.I. has fallen is due to the fact that we focus our attention on the relapsing case that does resist all forms of treatment and forget the ninety-and-nine that go their way rejoicing.

Towards the end of the war the hospital to which I was attached as pathologist became a centre for dealing with officers returning to the London area with dysentery; and amongst the considerable number of cases of bacillary, amœbic, and clinical dysentery that thus came under the care of Sir William Hale-White, who was in charge of the dysentery huts, there were 33 cases in whom infection by *E. histolytica* had been discovered and who were stated to be either still infected after emetine treatment or else only recently treated and with subsequent tests for "cure" still uncompleted. The test for "cure" was that officially laid down—viz., six negative examinations of the stools during the three weeks following the treatment with at least three tests in the third week. Of the 33 cases, 12 appeared on close investigation to have had efficient emetine treatment (probably E.B.I.) and gave the necessary number of negative tests; all the others showed either amœbæ or cysts in the stools or else gave a very doubtful history of previous treatment, and in view of our previous experience of the disease in the ordinary routine of the hospital all these cases were at once given a course of E.B.I. followed by a second course when necessary; 13 of these cases then gave the necessary six negative tests. This left us with 8 cases which we regarded as resistant to E.B.I. and 75 per cent. of "cures." Since then in the ordinary routine of a civil hospital I have come across six cases of amœbic dysentery either undiagnosed after months of suffering or else correctly diagnosed but having had no definite course of emetine treatment; four of these were relieved of their symptoms and their stools freed from cysts and amœbæ by E.B.I., one is still under observation, the stools being as yet free but the final tests incomplete, one left the hospital greatly improved but with the tests incomplete; the last case has probably relapsed as the drug was given intermittently owing to uncontrolled vomiting. In saying so much in favour of E.B.I. I have no wish to claim that in those cases where the stools are apparently freed from cysts and amœbæ for a mere three weeks there is any proof that the infection is really at an end. For all I know it may be that no one who has once been infected by *E. histolytica* has ever lost the infection; and I do know that of the cases quoted above at least two still have mild recurrent attacks of diarrhœa when cysts are to be found in the stools. But even if emetine does not produce a complete sterilisation so far as *E. histolytica* is concerned, so long as it can in many cases change a life of miserable discomfort into one of almost normal health it surely deserves our blessing.

Whilst on this subject I would like once more to urge the trial of the oil of chenopodium in those cases which resist all forms of emetine treatment and in which symptoms persist. Of the 33 cases under Sir William Hale-White quoted above 8 failed to respond to E.B.I.; 7 of these were treated with the oil of chenopodium; 3 were relieved of their symptoms and gave six negative stool examinations; 2 were completely unaffected by the drug, and 2 were transferred with only three negative tests when the hospital was closed. These results, however meagre, suggest that the drug is at least worth trying. I am aware that in some quarters it is considered too dangerous a drug to use, and on one occasion when advocating its trial in a discussion I was told by high authority that it was too dangerous a drug to play about with. I ask no one to play with this or any drug, but inasmuch as it is now in routine use in America as the recognised treatment in hookworm disease and has been given to thousands of people, children included, the difficulties of its trial in this country are surely not insuperable.

I am, Sir, yours faithfully,
GORDON W. GOODHART.

Warwick Gardens, Kensington, Jan. 11th, 1923.

SOLUBILITY OF EMETINE-BISMUTH-IODIDE.

To the Editor of THE LANCET.

SIR,—I notice Major P. M. Rennie, in his paper on the Treatment of Amœbiasis in your issue of Dec. 30th, 1922 (p. 1374), says emetine bismuth iodide (E.B.I.) is insoluble in dilute acid and that it passes through the stomach unchanged. May I say this is really not the case. I made experiments on the subject several years ago, and have given my results on p. 517 of the Extra Pharmacopœia (Vol. I.). It is stated there, for example, that if 0·1 g. of E.B.I. be shaken with 200 c.cm. of 0·2 per cent. hydrochloric acid, an opalescent liquid is formed containing bismuth as oxychloride and *emetine in solution*. The solubility of the alkaloidal portion of the compound in physiological acid, especially at body temperature, completely upsets the theory under which the compound was introduced.—I am, Sir, yours faithfully,

W. H. MARTINDALE, Ph.D.

10, New Cavendish-street, London, W. 1, Jan. 10th, 1923.

SULFARSENOL IN THE TREATMENT OF SYPHILIS.

To the Editor of THE LANCET.

SIR,—May I be permitted to comment upon Mr. F. C. Doble's interesting article with this title, which appeared in THE LANCET of Jan. 13th.

Mr. Doble mentions that certain cases of syphilis which reacted badly to other arsenobenzol compounds were refused other treatment than mercury and pot. iod. by certain syphilologists, and that the situation was saved with sulfarsenol. One might conclude that this drug was the only remedy. I am sure many will agree with me that the difficulty can be overcome otherwise. I have repeatedly counteracted these bad effects by making the patient avoid exposure to cold, allowing a certain amount of food before the injection, and by giving contramine intramuscularly.

I have also found contramine exceedingly useful in the complications of acute gonorrhœa, in fact, it is almost specific in aborting acute epididymitis and prostatitis. If sulfarsenol acts likewise then I would think it is by virtue of its sulphur radicle. In that case contramine is the safer remedy.

I am, Sir, yours faithfully,

Harley-street, W., Jan. 13th, 1923. M. W. BROWDY.

AN ALIEN ASTHMA CURE.

To the Editor of THE LANCET.

SIR,—I wish to inform the editorship of THE LANCET that I have heard through the managing director of the Olpena, Ltd., London, S.W. 1, 35, Duke-street, that it has been said in two or three publications of THE LANCET that the editorship has not been able to find my name in the German medical registers. I am herewith informing the editorship of THE LANCET, of which I am not a reader, that I am physician-general (out of service) of the Imperial German Navy, and it might be known to THE LANCET that in the ranks of our Imperial Navy only and solely first-rate physicians were taken up. If the editorship would take the pains to look for my name in the annual sets 1899–1918 of the lists of the Imperial German Navy they are sure to find the same in every annual set. During the last period of my active service I had the honour of being division-physician of the second division of the German Navy in Flanders, and have only taken my leave owing to the breaking out of the German revolution. I hope that these statements will suffice THE LANCET, and that it will make haste to set right the remarks about my name.

I am, Sir, yours faithfully,
DR. HANS ROHDE,

Düsseldorf, Jan. 13th, 1923. Marine-Generalarzt a.D.

⁎⁎⁎ Fleet-Surgeon Rohde has been misinformed. In the circular in which he was stated to be in charge of a treatment centre in London he was described as "a specialist in bronchial diseases." We said (once only) that we had failed to find his name on the *British* Medical Register, or in any book of reference containing the names of German *specialists*.—ED. L.

Obituary.

JOHN BERRY HAYCRAFT, M.D., D.Sc. EDIN., F.R.S. EDIN.,

EMERITUS PROFESSOR OF PHYSIOLOGY, UNIVERSITY COLLEGE OF SOUTH WALES.

ALL who knew Prof. Haycraft will hear with deep regret of his sudden death at Royston on Dec. 30th last. Throughout his life, and in spite of serious illness, he had steadfastly held the ideal of scientific research before himself; and when he resigned his chair at Cardiff in 1920 it was in the hope that he would be able to continue his investigations in his retirement. For a time his health improved, and his friends hoped that he would be enabled to enjoy many years in the quiet pursuit of physiological problems. But this was not to be.

John Berry Haycraft was born in 1857, educated at Brighton Grammar School, and entered on a medical course at Edinburgh University, where he obtained the gold medal for his M.D. thesis in 1888; in the same year he took his D.Sc. After studying in

Leipzig he was appointed to the chair of physiology at Mason College, Birmingham. He was, for a short time, interim professor at Edinburgh during Prof. Rutherford's illness ; and, on Rutherford's resumption of his duties, in 1894 he became the first professor of physiology at University College, Cardiff. During his tenure of this chair from 1894 to 1920 he saw the gradual development of the Medical School, retiring, in fact, only a few months before the reconstitution of the school as the Welsh National School of Medicine. Haycraft's vigorous insistence upon the necessity of a thorough scientific basis in medical education did much to mould the future development of the school, and its present organisation—with its six years of medical study, restriction of its medical degrees to students who have first attained a degree in science, and whole-time professors in the clinical subjects—owes much to his foresight. His advocacy of modern ideals of teaching and research may not have been popular in all circles, but was no mean factor in determining the course of events.

Perhaps the greatest monument to Prof. Haycraft's activities is the magnificent Physiology Institute which had just been completed before his retirement. He was fortunate in finding a munificent patron in Sir William James Thomas, and an exceptional architect in the late Colonel Bruce Vaughan, who went to endless trouble in visiting other laboratories whilst designing the Cardiff Institute. The result of this collaboration was an institute which is amongst the largest, if not actually the largest, in this country, as it is also one of the most satisfactory in design.

The best known of Haycraft's contributions to physiology is his work upon the cross-striation of skeletal muscle (1881 and 1891). He made casts of skeletal muscle fibres by pressing them upon collodion films, and he found that the impression left upon the film had the same cross-striated appearance as the muscle fibre itself. From this he concluded that the cross-striated appearance is an optical phenomenon due to different refractive effects of the globular and restricted portions of muscle fibrils which are varicose in shape. He contributed articles upon Animal Mechanics, the Sense of Taste, and the Sense of Smell to Schafer's great text-book of Physiology ; and his subject for the Milroy Lectures of 1894 was "Darwinism and Race Progress." These were, however, but a small part of his contributions to science. To name but a few of the subjects which he investigated is to show the range of his interests : The results of temperature variations ; the chemistry of the blood ; the cell-walls of hepatic cells ; a theory of amœboid movement ; limitations in time of conscious sensations ; action of a secretion obtained from the medicinal leech on the coagulation of the blood ; nature of the objective cause of sensation ; taste ; smell ; reflex spinal scratching movements ; coagulation of the blood ; ciliated epithelium ; chromatology of the bile ; nature of a voluntary muscular movement ; vision. Amongst his longer papers were several upon the physiology of the heart ; the cause of the first sound ; the movements of the heart within the chest cavity ; the time of contraction of the papillary muscles (with Paterson) ; the changes in shape of the heart (with Paterson) : and other papers on luminosity ; rapid voluntary movements ; the elasticity of animal tissues ; the blind spot ; and the development of the kidney.

Throughout his life Prof. Haycraft showed himself a man of vision, determination, and high scientific ideals, qualities of which the Cardiff Physiology Institute is a fitting memorial. His friends will remember that these qualities survived undimmed an illness which incapacitated him (as it did Pasteur) in the middle years. They will remember him for this, and because he never did a mean thing.

Prof. Haycraft was thrice married. He leaves a widow and two sons, one of whom bears his father's name and is on the surgical staff of the Prince of Wales's Hospital, Cardiff, and assistant in the surgical unit of the National School.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a quarterly meeting of the Council of the College held on Jan. 11th, Sir Anthony Bowlby, the President, in the chair, the undermentioned diplomas were conferred (in conjunction with the Royal College of Physicians of London) upon the following candidates :—

DIPLOMA OF M.R.C.S.

Marjorie Broadbent, Royal Free : B. W. Roffey, St. Mary's ; and Marguerite A. M. Xavier, Royal Free.

A report was read from the secretary to the Conjoint Examining Board respecting candidates found qualified for the diploma in Public Health, and diplomas were granted (conjointly with the Royal College of Physicians) to the following 24 candidates.

DIPLOMA IN PUBLIC HEALTH.

W. M. Binning, Univ. Coll. ; M. C. Brereton, Edinburgh and Univ. Coll. ; H. Brookman, St. George's and Middlesex ; Alida Charlotte Burt, Dublin and Univ. Coll. ; G. W. Cheater, Charing Cross and Roy. Inst. Public Health ; D. Clyde, Glasgow and Univ. Coll. ; E. Cotter, Dublin and Royal Army Med. Coll. ; A. J. Cronin, Glasgow ; J. A. A. Duncan, Edinburgh and Middlesex ; G. D. English, Edinburgh and Roy. Inst. Public Health ; Dorothy W. Gowers, Royal Free and Univ. Coll. ; C. M. Gwillim, St. Bart.'s ; G. Habgood, Cambridge and London ; C. E. E. Herington, St. Bart.'s ; A. N. Kingsbury, Middlesex : T. McClurkin, Belfast and Univ. Coll. ; J. W. Mann, Aberdeen and Univ. Coll. ; K. Nain, Punjab and Univ. Coll. ; C. C. Okell, Cambridge and Guy's ; R. R. Scott, Durham and Middlesex ; J. Singh, Punjab and Univ. Coll. ; R. M. Soames, Cambridge and St. Bart.'s ; Elsie Stansfeld, Cardiff and Royal Free ; and E. W. L. Thomas, St. Bart.'s.

A report was read from the secretary to the Conjoint Examining Board respecting candidates found qualified for the diploma in Tropical Medicine and Hygiene, and diplomas were granted to the following 13 candidates mentioned in the report.

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.

W. T. Benson, Edinburgh ; T. L. Bomford, St. Bart.'s : O. T. Brosius, U.S.A. ; C. A. Calder, Edinburgh ; G. Covell, Guy's ; B. C. Dasgupta, Calcutta ; Helen Gregory, Edinburgh ; W. H. Hamilton, St. Bart.'s ; H. A. Hewat, Edinburgh ; M. J. Holgate, St. Bart.'s ; K. Nain, Punjab ; C. G. Pandit, Bombay ; and C. J. H. Sharp, Univ. Coll. (All these candidates studied at the London School of Tropical Medicine.)

A report was read from the secretary to the Conjoint Examining Board respecting candidates found qualified for the diploma in Psychological Medicine, and diplomas were granted to the following 13 candidates jointly with the Royal College of Physicians.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

Mary Barkas, National and Bethlem Hosps. ; S. Blanton, Cornell ; N. H. Clubwala, Maudsley and Bethlem Hosps. ; J. Gifford, Bethlem ; G. W. Greene, Claybury Ment. Asylum ; F. H. Guppy ; E. L. Hopkins, Bexley Ment. Hosp. ; P. D. Hunter, Arlesly Ment. Hosp. ; P. McLuskie, Maudsley and Colney Hatch ; N. W. Markwell, Bethlem ; N. Roberts, Horton and Ewell Ment. Hosps. ; W. D. Sammon, Colney Hatch ; and C. E. A. Shepherd, Maudsley and Epsom Ment. Hosps.

A report was read from the Committee of Management, and the revised regulations for the diploma in Public Health were approved and adopted.—Sir W. Thorburn was nominated to serve on the Council of Queen Victoria's Jubilee Institute for Nurses, as representative of the College, for three years from March 1st, 1923, in the vacancy occasioned by the expiration of the period of office of Sir Charters J. Symonds.

The lecture arrangements of the College for January and February have been issued. The dates and subjects are as follows :—Jan. 29th : Osteitis Fibrosa, by Prof. R. Lawford Knaggs ; Jan. 31st : Malignant Disease of the Upper Jaw with Special Reference to Operative Technique, by Prof. Musgrave Woodman ; Feb. 2nd : The Metastatic Tumours of Bone, by Prof. Cecil A. Joll : Feb. 5th : The Relation of Diseases of the Gall-bladder to the Secretory Function of the Stomach and Pancreas, by Prof. H. Ernest Griffiths : Feb. 7th : Chronic Mastitis, by Prof. Geoffrey Keynes : Feb. 9th : Remote Effects of Gunshot Wounds of the Head, by Prof. L. Bathe Rawling ; Feb. 21st : The Flow of Lymph from the Ileo-cæcal Angle and its Possible Bearing on (1) the Formation of Gastric and Duodenal Ulcer, and (2) the Cause of Other Types of Indigestion, by Mr. R. L. Braithwaite : Feb. 23rd : Abnormalities of the Hepatic and Cystic Arteries and Bile Ducts, by Mr. E. R. Flint. All these lectures will be delivered at 5 P.M. On Feb. 14th, the Hunterian oration will be delivered at 4 P.M. by Sir John Bland-Sutton. Admission to all lectures is free.

University of Liverpool.—At examinations held recently the following candidates were successful :—

Diploma in Public Health.

Christine C. Abernethy, Esther Ashworth, A. E. I. Connolly, C. E. Freeman, and A. Speight.

Royal Institution of Great Britain.—The Friday evening discourse on Jan. 26th will be delivered at 9 P.M. by Sir Almroth Wright, F.R.S. The subject is the Machinery of Anti-Bacterial Defence. On Jan. 23rd, at 3 P.M., Prof. F. G. Donnan, F.R.S., will give a second lecture on Semi-Permeable Membranes and Colloid Chemistry.

Association of Economic Biologists. — The annual general meeting of the Association will be held at 2.30 P.M. on Jan. 26th, in the Botanical Lecture Theatre of the Imperial College of Science, Prince Consort Road, South Kensington, London, S.W. 7, when Prof. R. T. Leiper will give an address on the Study of Helminthology.

London Hospital Medical College.—A course of eight lectures on the Mathematical Basis of Physiological Problems will be given by Dr. W. A. M. Smart, at 4.30 P.M., on Jan. 18th and 25th, Feb. 1st, 8th, 15th, 22nd, and March 1st and 8th. Attendance at this Course is recognised in connexion with the B.Sc. (Honours) Degree in Physiology. Admission to these lectures is free without ticket.

The late Dr. W. C. Steen.—Dr. William Carmichael Steen died at Letchworth, Herts, on Jan. 4th, in his sixtieth year. He was the eldest son of the late Dr. Robert Steen, of the Royal Belfast Academical Institution. Dr. Steen qualified from the Royal University of Ireland, where he became M.D., M.Ch. in 1886, and practised at Owston Ferry, Lincolnshire, and at Belfast. For many years he was laid aside from active work by spinal caries, and he bore his long illness with patience and cheerfulness. Among his many occupations must be included the work that he did for the library for the blind. He not only mastered the difficulties of Braille and transcribed books by this method but was a recognised instructor in the subject. He married in 1900 Margaret, youngest daughter of the late William Eaden Lilley, of Cambridge, who survives him.

Royal Medical Benevolent Fund.—At a recent meeting of the committee 31 cases were considered and £417 granted to 29 applicants. The following is a summary of some of the cases relieved :—

M.R.C.S., L.R.C.P. Lond., aged 67, married, four children, who practised at Bury St. Edmunds and latterly has taken locums. He is at present unable to obtain any work, principally through old age. His wife and family live in the Isle of Wight and applicant is staying in London to be near the medical agents. An emergency grant of £5 was given to help to keep him, and a further £15 was voted at the meeting.

Son (aged 18) of M.R.C.S., L.S.A. Lond., M.D. Father now insane. Applicant is now at a training college in Switzerland, and a further 18 months is required to complete the training. The friends are willing to contribute a sum of £50 if the Fund could supply a similar sum. The Fund voted the sum of £25 and the R.M.B.F. Guild contribute the balance.

Daughter (aged 23) of M.R.C.S. Eng. and L.R.C.P. Edin. who practised at Stockton-on-Tees and died in 1920. Applicant for some time has been engaged as a clerk, but finding that there would be some reduction of staff she took this opportunity to enter a hospital as probationer nurse. She asked the Fund to help her to purchase outfit. The sum of £7 2*s.* 2*d.* was paid by the R.M.B.F. Guild, and the Fund voted the sum of £4 towards this amount.

Widow (aged 40) of M.B. Lond. who practised at Richmond and latterly held public appointments and died in 1918. Applicant was left to provide for her two children, aged 9 and 7, and asked for help towards education, but as her income is in excess of the condition of help from the Fund they voted the sum of £1 to qualify her for assistance from the R.M.B.F. Guild in helping to get the son into Epsom when old enough.

Widow (aged 45) of M.B., C.M. who practised in Guildford and died in January, 1922. After the husband died the practice was sold, and when funeral expenses and debts were paid there was only £120 left for applicant and three sons. This case received grants from the War Emergency Fund, and at present this Fund is paying the sum of £45 for one year's school fees for the youngest son. Another fund is helping with the maintenance grant, and the current expenses of the 12 months has reduced the applicant's balance to £30. The older son is a clerk, who earns £100 per annum, out of which he gives his mother £40 towards his keep. The rent of a small flat amounts to £78 per annum. Voted £18 in 12 instalments.

Daughter (age 66) of M.D. Lond. who practised at Notting Hill and died in 1885. This applicant was able until recently to earn money at needlework, but owing to ill-health and failing eyesight had to give it up. She was granted by the Fund in March, 1922, £26 in 12 instalments. This case was chosen as the most deserving to receive a special grant of £1, which has been given to the Fund for a suitable unmarried grantee.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, K.B.E., C.B., M.S., at 11, Chandos-street, Cavendish-square, London, W. 1.

A **window** has been erected in St. Mary's Church, Ticehurst, Sussex, to the memory of Dr. Herbert Francis Hayes Newington who died in the summer of 1917.

Ivory Cross Dinner.—A dinner in aid of this charity, which provides dental treatment for those who are really poor in every class of life, will be held at the Hotel Victoria, Northumberland-avenue, London, W.C., on Feb. 9th. Tickets (£1 1*s.*) may be obtained from Miss Fletcher, Hon. Secretary, 10, Henrietta-street, London, W. 1.

Foreign Decorations.—The King has granted permission to Dr. A. Granville, C.M.G., C.B.E., President of the Sanitary Maritime and Quarantine Council of Egypt, to wear the Cross of Commander of the Order of Leopold II., and to Dr. J. M. Coplans, to wear the Cross of Chevalier of the Order of the Crown, conferred on them by the King of the Belgians in recognition of valuable services during the war.

The Proposed Testimonial to Dr. Byrom Bramwell.—A Provisional Committee has been formed to mark in some definite and, if possible, permanent manner the high esteem felt for Dr. Bramwell by many members of the medical profession on the occasion of his seventy-fifth birthday. The names of the Provisional Committee are Sir Clifford Allbutt, Sir Thomas Barlow, Sir James Crichton-Browne, Sir Dyce Duckworth, Sir Frederick Mott, Sir Robert Philip, Sir James Purves-Stewart, Sir David Drummond, Prof. Lovell Gulland, Dr. Robert Hutchison, Mr. H. J. F. Simson, Dr. S. A. K. Wilson, Dr. J. Brunton Blaikie, Dr. G. H. Rae Gibson, and Dr. F. N. Kay Menzies (Hon. Secretary and Treasurer). Several suggestions have been made as to the form which the presentation should take—e.g., a portrait by a well-known artist—and the Committee is prepared to receive other suggestions. It is proposed to limit subscriptions to a maximum of £5, but any subscription, however small, will be welcomed. Subscriptions should be sent to Dr. Menzies, 37, Egerton-gardens, London, S.W. 3.

A Dublin Surgeon Kidnapped.—Our Irish correspondent writes: Mr. O. St. J. Gogarty, the Dublin throat surgeon and a member of the Senate of the Irish Free State, had an unpleasant adventure on the night of the 12th inst. On that evening a party of armed men called at his residence and informed him that they required his professional assistance for a patient who was seriously wounded. Forcing him into a motor-car and blindfolding him they then drove to a house just outside Dublin, between Island Bridge and Chapelizod on the river Liffey. He was left in a room under an armed guard. After a little time he asked permission to withdraw to the garden. This was granted, an armed man still guarding him. Removing his overcoat, and making a feint of handing it to the guard, he succeeded in throwing it over the head of the latter and momentarily disabling him. Mr. Gogarty dashed through a shrubbery and plunged into the Liffey. Swimming down stream for some time he reached the bank and ultimately succeeded in reaching the Depôt of the Civil Guard in the Phœnix Park little the worse for his night's adventure. It is supposed that Mr. Gogarty, as a senator, was seized as a hostage for one of the Republican leaders who has recently been on his trial. His professional brethren congratulate him on his escape, which was due to his own remarkable courage and resource.

People's League of Health—The Sims Woodhead series of constructive educational health lectures will be given at the headquarters of National Union of Teachers, Hamilton House, Mabledon-place, London, W.C. 1, on Wednesday at 6 P.M., during January, February, and March. At the conclusion of the series there will be an optional examination, and certificates issued by the Medical Council of the People's League of Health, with a travelling scholarship prize award consisting of a week's visit to a foreign country, with facilities for visiting its health centres. The first lecture was held on Jan. 17th, when Prof. T. B. Johnston gave an address on the Anatomy and Physiology of Bones and Muscles and Internal Organs. On Jan. 24th Prof. M. S. Pembrey will deal with the Anatomy and Physiology of the Circulatory and Respiratory Systems. On Jan. 31st Sir Frederick Mott, F.R.S., will lecture on the Brain and Nervous System. On Feb. 7th Sir Harry Baldwin will speak on the Teeth, and on Feb. 14th Prof. W. Halliburton, F.R.S., on Food. Prof. E. H. Starling, F.R.S., will lecture on Digestive Organs and Lymphatic Glands on Feb. 21st, and on Feb. 28th Sir William Arbuthnot Lane will discuss Sewage Systems of the Human Body. The lectures on March 7th, 14th, and 21st will be delivered by Prof. H. R. Kenwood, Mr. E. B. Turner, and Dr. A. F. Tredgold, respectively, on Hygiene, Recreation and Physical Exercise, and Development and Function of Mind. The fee for the series will be 10*s.* Tickets can be obtained from the Hon. Organiser of the League, 12, Stratford-place, London, W. 1.

EASTBOURNE HOSPITAL.—By means of the Penny-a-Week Fund, which was inaugurated at Eastbourne some years ago to help the local hospitals by the collection of pennies, the sum of £968 was raised during 1922, an advance on the previous year of £95.

THE LATE DR. J. D. DICKSON.—Dr. John Dunbar Dickson, who died on Jan. 13th, aged 70, was educated at Queen's College, Belfast, and graduated M.D., M.Ch. R.U.I., in 1876, taking in the same year the L.R.C.S.I. and the L.M. of the Rotunda Hospital. After holding various house appointments in Ireland, at the Darlington Hospital, the Bucks General Infirmary, and the Ripon Dispensary, he became a partner in a practice at Marlow from which he retired in 1914, though he resumed work during his successor's absence on war service. For many years he was medical officer of health to the Marlow Urban District Council and to the Wycombe Rural District Council, and was also assistant school medical officer for Marlow. Dr. Dickson took a keen interest in local affairs; he was a member of the Bucks Insurance Committee and a founder of the Bucks Cottage Hospital, on the staff of which he served. He was appointed a justice of the peace in 1906.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, Jan. 22nd.

ODONTOLOGY: at 8 P.M.
Discussion:
On Dental Sepsis as an Ætiological Factor in Disease of Other Organs.
To be opened by Sir William Willcox.

Tuesday, Jan. 23rd.

MEDICINE: *at University College Hospital, Gower-street, W.C.*
Clinical Meeting at 5.30 P.M. (Tea will be provided at 5 P.M.)

Thursday, Jan. 25th.

UROLOGY: at 8.30 P.M.

Clinical and Pathological Meeting.

Cases and Specimens will be shown by—
Sir John Thomson-Walker: (1) A Cyst of the Prostate. (2) A Growth of the Epididymis. (3) An Aberrant Lobe of the Prostate. (4) Case of Malakoplakia (Mr. F. R. F. Barrington).
Mr. W. Girling Ball: (1) Ligature of Abnormal Renal Artery with Necrosis of the Kidney. (2) Papilloma of the Kidney. (3) An Absent Kidney with Congenital Deformity of the Opposite Side.
Dr. W. G. Sutcliffe: Case of Large Calculus from the Male.
N.B.—Will Members desiring to show specimens kindly notify Mr. Girling Ball, 77, Wimpole-street, W., as soon as possible.

Friday, Jan. 26th.

STUDY OF DISEASE IN CHILDREN: at 5 P.M. (Cases at 4.30 P.M.)
Special Clinical Meeting to be devoted to the exhibition and discussion of cases showing the late results of Encephalitis Lethargica.

NEUROLOGY:
Members of this Section are especially invited to show cases and take part in the meeting.

Jenner Centenary.

Sir William Hale-White will given an Address on Jenner and his Work at 8.30 P.M.
An oil painting of Jenner by Hobday, presented to the Society by Dr. W. S. A. Griffith, will be on view, and Mr. C. J. S. Thompson, of the Wellcome Historical Medical Museum, has kindly offered to show a collection of relics and exhibits connected with Jenner.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Jan. 22nd.—8.30 P.M.: Discussion on Clinical Results of Treatment of Malignant Disease by X Ray—introduced by Dr. Robert Knox, followed by Mr. Hayward Pinch, Dr. Reginald Morton, Mr. Sampson Handley, Dr. Douglas Webster, Dr. J. E. A. Lynham, and others.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.
MONDAY, Jan. 22nd.—11 A.M., Mr. Maingot: Surgical Ward Cases. 12 noon, Mr. Simmonds: Applied Anatomy. 4 P.M., Mr. Bishop Harman: Congenital Defect of the Eyes.
TUESDAY.—11 A.M., Dr. Paterson: Demonstration of Medical Cases. 12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Mr. Tyrrell Gray: Surgical Wards.
WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 12 noon, Dr. Burnford: Pathological Demonstration. 2.30 P.M., Mr. Armour: Surgical Wards.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 12 noon, Mr. Simmonds: Demonstration of Fractures. 4 P.M., Dr. McConnel Wanklyn: Small-pox Diagnosis.
FRIDAY.—12 noon, Dr. Flett: Radiology. 2 P.M., Mr. Banks-Davis: Diseases of Throat, Nose, and Ear. 3 P.M., Mr. Sinclair: Surgical Cases.
SATURDAY.—9 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 11 A.M., Mr. Maingot: Surgical Pathology.
Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M.: In-patients, Out-patients, Operations, Special Departments.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: JAN.–MARCH, 1923.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, Jan. 22nd.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Lecture:—Tabes Dorsalis and its Treatment: Dr. James Taylor.
TUESDAY, Jan. 23rd.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Lecture:—Myopathy: Dr. Adie.
THURSDAY, Jan. 25th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Lecture:—Tonic Fits and Allied Forms of Generalised Muscular Spasms: Dr. Walshe.
FRIDAY, Jan. 26th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Lecture:—Friedreich's Ataxia: Dr. Saunders.
Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

NEURO-PATHOLOGY.

MONDAY, Jan. 22nd.—12 noon, Cerebro-Spinal Fluid: Dr. J. Godwin Greenfield.
N.B.—A Course of Lectures in the Anatomy and Physiology of the Nervous System will be given if there are sufficient entries for it.
The fee for the whole Course, including Anatomy and Physiology, is £12 12*s.*, but these Lectures may be taken separately for a fee of £4 4*s.* Course without Anatomy and Physiology Lectures will be £10 10*s.* Any part of the Course may be taken separately at a special fee. Special arrangements will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the office on entering for the Course.
C. M. HINDS HOWELL, Dean of Medical School.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, Jan. 25th.—4 P.M., Mr. Fairbank: Fractures About the Elbow-joint and Their Complications.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.
THURSDAY, Jan. 25th.—5 P.M., Dr. W. Griffith: Diseases of the Skin Appendages.

ST. MARY'S HOSPITALS POST-GRADUATE LECTURES (Whitworth-street West Branch).
FRIDAY, Jan. 26th.—4.30 P.M., Dr. C. P. Lapage: The Exudative Diathesis in Children. (Eczema, Urticaria, Hay Fever, and Asthma.)

MANCHESTER FRENCH HOSPITAL, 24, Acomb-street, Whitworth Park.
THURSDAY, Jan. 25th.—4.30 P.M., Dr. N. C. Haring: Clinical Demonstration of Cases of Tuberculosis of the Lungs.

MANCHESTER CLINICAL SOCIETY.
Clinical Meeting at the Skin Hospital, Quay-street.
THURSDAY, Jan. 25th.—4.30 P.M.

Appointments.

HUMPHERY, G. P., M.B., C.M. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Acts for Brandon, Suffolk.

Ingham Infirmary, South Shields: GOGGIN, J. J., M.B., B.Ch., B.A.O., Senior House Surgeon; LITTLE, R. C., Junior House Surgeon.

Vacancies.

For further information refer to the advertisement columns.

Barnsley, Beckett Hospital and Dispensary.—Sen. H.S. £300.
Birmingham City.—Research Officer. £500.
Birmingham General Hospital.—Two H.P.s. £70.
Bristol General Hospital.—Hon. Phys. Accoucheur. Also Asst. Phys. Accoucheur.
Bristol Mental Hospital.—Asst. M.O. and Pathologist. £400.
Cape Town, City of.—M.O.H. £1500.
City of London Hospital for Diseases of Chest, Victoria Park, E.—Asst. M.O. £100.

Colchester, Essex County Hospital.—Cas. O. and Path. £200.

Croydon County Borough.—M.O.H. £1300.

Dreadnought Hospital, Greenwich.—H.P. £150. Also S. for Dis. of Throat, &c.

East Ham Education Committee.—Part-Time Ophth. S. £3 3s. per session.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—H.P. £125.

Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—Hon. Clin. Assts. Also Asst. to Clin. Pathologist. £100.

India, Countess of Dufferin's Fund, Women's Medical Service.—Two Med. Women. Rs.450 p.m.

Kidderminster Infirmary and Children's Hospital.—H.S. £150.

Liverpool Eye and Ear Infirmary.—Hon. Asst. S.

Liverpool Maternity Hospital and Ladies Charity.—Hon. S.

Liverpool Royal Children's Hospital.—Two Res. H.P.'s and Two Res. H.S.'s. Each £90.

London Homœopathic Hospital, Great Ormond-street, W.C.—Asst. P. for Dis. of Women.

Manchester, Ancoats Hospital.—Hon. Radiologist. £100.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Margate, Royal Sea Bathing Hospital for Surgical Tuberculosis.—Res. S. and Med. Supt. £500.

Napsbury Mental Hospital.—Jun. Asst. M.O. £546 14s.

Northampton County Borough Education Committee.—Asst. Sch. M.O. and Asst. M.O.H. £600.

North Staffordshire Infirmary, Hartshill, Stoke-on-Trent.—H.S. £250.

Norwich, Norfolk and Norwich Hospital.—H.S. £150.

Preston and County of Lancaster Queen Victoria Royal Infirmary.—Res. Surg. O. and H.S. £225 and £200 respectively. Also Hon. M.O. for Obstetric Dept.

Queen Mary's Hospital for the East End, Stratford, E.—Cas. O. £150.

Reading, Royal Berkshire Hospital.—H.P. £200.

Rotherham Hospital.—Jun. H.S. £150.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Pathologist. £200.

Royal Westminster Ophthalmic Hospital, King William-street, Strand, W.C.—Radiologist.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—H.S. £100.

Shoreham, Sussex, Lancing College.—School Doctor. £500.

South London Hospital for Women, Clapham Common, S.W.—Sen. H.S. £100. Also Second H.S. £50.

Staffordshire General Infirmary, Stafford.—H.S. £200.

University College Hospital, Gower-street, W.C.—Asst. in Child Welfare. £50.

University of London.—External Examiners, &c.

Weston-super-Mare Hospital.—H.S. £150.

Whittingham County Mental Hospital, near Preston, Lancs.—Asst. M.O. Also Asst. M.O. Pathologist. Each £449 13s.

Wigan Infirmary.—Hon. Asst. Physician.

Worcester County and City Mental Hospital, Powick.—Jun. Asst. M.O. £300.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Chapel-en-le-Frith (Derby), Ottery St. Mary (Devon), and Newport (Fife).

Births, Marriages, and Deaths.

BIRTHS.

Cox.—On Jan. 15th, at 49, West Cliff, Preston, the wife (née Rita Howarth) of George Lissant Cox, M.A., M.D. (Cantab.), of a daughter.

Denning.—On Jan. 7th, at Star-hill, Rochester, the wife of Dr. Fredk. A. V. Denning, of a son.

Emanuel.—On Jan. 13th, at Harborne-road, Edgbaston, Birmingham, the wife of J. G. Emanuel, M.D., F.R.C.P., of a son.

Luxmoore.—On Jan. 14th, at a nursing home, the wife of Surgeon-Major E. J. H. Luxmoore, 2nd Life Guards, of a son.

Ritchie.—On Jan. 6th, at The Groves, Malpas, Cheshire, the wife of T. C. Ritchie, M.D., of a daughter.

MARRIAGES.

Thomson—Fraser.—On Jan. 9th, at St. Margaret's Parish Church, Arbroath, James Ettershank Gordon Thomson, M.C., M.B., Ch.B., to Florence, fourth daughter of Mr. and Mrs. Robert Fraser, Cairnichill, Arbroath.

DEATHS.

Dickson.—On Jan. 13th at Marlow, Bucks, John Dunbar Dickson, M.D., aged 70.

Keefer.—On Dec. 27th, 1922, at Toronto, Canada, Major William Napier Keefer, I.M.S., retired.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

SOME NOTES ON THE TREATMENT OF FRACTURES.[1]

By Sir W. Arbuthnot Lane, Bart., M.S. Lond., F.R.C.S. Eng.

From the examination in the dissecting room of Guy's Hospital and elsewhere of the bodies of labourers who had been engaged in special occupations for many years, I formulated several laws on which I based the principles involved in the treatment of fractures. Later I applied the same principles to the elucidation of the condition which I called chronic intestinal stasis which, I believe, is the cause of all the diseases which are acquired as the result of civilisation. I will state the several laws as briefly as possible. They are:—

1. The skeleton represents the crystallisation of lines of force. When force is exerted habitually in one direction, bone is laid down as compact tissue, when it is exerted in varying directions it is laid down as cancellous tissue. These cancelli only retain their normal arrangement as long as the joint performs its normal functions, any variation in its range of movement from injury, disease, habit, or occupation being followed by a definite change in the arrangement of the cancellated bone. As regards the compact tissue a similar change ensues when the shaft of a long bone is broken and the ends of the fragments are not accurately opposed, so that the axes of the two portions are not in continuity. In such a case occurring in childhood an entirely new shaft is formed extending along the line of force—namely, from the extremities of the broken bone—any portion of the old shaft outside this line being absorbed. As life goes on the process of crystallisation in a fractured bone becomes more and more limited and localised and is usually described as callus. Even in advanced age, however, the process of formation of bone in the line of force may extend along the entire length of the shaft and be very abundant.

2. The rate of growth of bone in the several portions of an epiphysial line varies inversely as the pressure transmitted through them. This is shown very clearly in the changes that take place in the lower end of the growing femur in knock-knee and in bow legs.

3. Pressure produces changes in the form and function of bones and joints. It may immobilise joints that are normally movable or it may mobilise joints which originally allowed of a very slight degree of movement. It may convert cartilage into bone, as in the case of the first costal cartilages of the labourer and make a movable joint in its length.

4. Strain produces change in the form and function of bones and joints. It tends to convert muscles into tendon, tendon into ligament, and ligament into bone.

5. When apart from the exercise of pressure or strain it is important in the special relationship of the individual to his surroundings that an existing mechanism should be altered or an entirely new one developed such a change takes place.

6. The several organs exert a varying claim upon the bone-forming centre. This is well illustrated in the characteristic thickening of the skull in mollities ossium, rickets, and osteitis deformans.

These laws show that we bear a certain definite mechanical relationship to our surroundings, and that any modification in that relationship is followed of necessity by a corresponding alteration in the structure of the body of the individual. In this way evolution is clearly demonstrated by the extraordinary and extensive changes which take place during the lifetime of an individual from the pursuit of any laborious occupation. They are precisely what one would expect to arise from a study of the variation in the relationship of the mechanics of the individual to his surroundings. They are modified in a very remarkable manner by the vitality of the individual. This is shown by a contrast of the bony changes in the labourer with such as are seen in the skeletons of those affected with lateral curvature of the spine or other resting deformity. Again, even more remarkable differences are observed in the soft parts, as in the case of the abdominal viscera in chronic intestinal stasis. While in the vigorous subject the overloaded bowel becomes fixed by dense strong acquired bands which retain it in position and oppose its distension and prolapse, in the feeble subject no attempt whatever is made to control the distension and prolapse of the large bowel which may become enormously elongated. All this has been described in detail elsewhere. Whether I was justified in assuming the truth of the following law you must decide on the evidence I put forward. It is :—

---

[1] Abstracted from an address delivered to the St. Mary's Hospital Medical Society on Jan. 10th.

7. Tendencies to change which cannot produce the result in the parent may do so in the offspring.

If this law is true it is that on which evolution is founded.

Treatment of Fractures of Long Bones.

While pursuing these investigations of the changes which ensue in the various kinds of labourers I found a large number of fractures of the long bones which were quite common in the class that furnished the subjects in the dissecting room. This was accounted for by the fact that the malunion of such fractures involved such an amount of physical depreciation and of wage-earning capacity as to drive the man into the workhouse and thence to the dissecting room. The mode of union of the fragments was almost invariably bad as regards the form and function of the bone. This was particularly noticeable in the fractures of the long bones of the leg.

In order to confirm the extent of the depreciation in wage-earning capacity which ensued from fractures of long bones, and more especially those of the leg, I went to the workhouses, instrument makers, employers of labour, foremen of works, police authorities, and Poor-law officials, when I found that the loss sustained by the labouring class, and especially by those who had to climb on ladders and work on buildings, often in positions of considerable danger, was very great indeed.

On the strength of the information that I had acquired in this way I started in 1892 to operate on all cases of fracture in which it was important to the individual that his anatomy and functions should be restored to the normal if it was impossible to obtain accurate apposition of fragments by means other than operative. At that time the teaching of the text-books is illustrated by the following remarks by Mr. Christopher Heath, the then President of the Royal College of Surgeons of England, one of my most violent opponents. He stated that he "had no hesitation in asserting how important it is, in a fracture of the leg particularly, that the fracture should be set thoroughly and accurately, and unless that is done, and done accurately, the surgeon has not treated the case properly"; and again, "but I cannot conceive how anyone can believe that it is justifiable to convert a simple into a compound fracture, and of this I am quite certain that the majority of surgeons for the present will remain content with the usual methods of treatment."

I have chosen Mr. Heath amongst the large number of surgeons who were so actively opposed to any modification of the treatment of fractures then in use as he occupied an important position in the teaching world and also at the examination table. He, like most surgeons at that time, was strongly opposed to the antiseptic treatment, so that it was perhaps as well that he stuck to the old method which involved no immediate risk to the patient. The several opponents differed widely in the methods which they employed in their treatment. Believing that the chief factor opposing replacement of fragments was the spasmodic contraction of muscles and not as I demonstrated the shortening by hæmorrhage and inflammation of the soft parts which form ties in the length of the long bones, some advised the so-called "setting," a most unfortunate term since it suggests to the public the restoration of the broken bone to its normal form, be postponed till the spasmodic contraction of the irritated and lacerated muscles had subsided in a week or ten days. Others, as for instance, the late Sir Alfred Pearce Gould, took a different view as the following extract shows: "Having arrived at a full and correct diagnosis the next point to attend to is to reduce the fragments at once, at the earliest possible moment, remembering that lapse of time always increases the difficulties in doing this, never lessens them, and even makes them insuperable. The reduction must be complete or perfect at once."

I quote these statements made by two well-recognised authorities since they illustrate the teaching of that time together with the very marked confusion in the minds of surgeons as to the method to be adopted in the treatment of fractures. Every surgeon was agreed that my statements as to the union of fragments in bad position and the consequent depreciation in wage-earning capacity were grossly exaggerated. It was only when X rays had come into use that it was shown that not only were they not exaggerated but that the mechanical conditions were even worse than I had represented.

Feeling became so acute on this subject that at a meeting of the British Medical Association held in London many years ago a demand was made by several members that a committee should be appointed to investigate the accuracy of my statements. The Association willingly undertook the task and a committee was appointed consisting of several distinguished surgeons who carried out the investigation very thoroughly at the cost of much time and money. The report, which was published by the Association, fully bore out the truth of my statements and was far-reaching in its importance. I have followed with complete success the method of treatment that I laid down in 1893, modifying it only slightly in the form of the materials used to retain the fragments of the broken bone in position. This method has been widely adopted, and when the surgeon has possessed mechanical skill and judgment, together with a perfect technique, the best possible results have been obtained. Unfortunately many operators have not possessed these qualifications and much harm has resulted partly from their inability to replace the fragments in position, or to secure them efficiently, or from sepsis. This last fault especially has led to serious trouble such as death, amputation, and the removal of plates from infection of the wound. As is natural, these operators did not attribute their failures to their own want of skill but preferred to lay the blame on the operation. They modified the form and structure of the plates, they altered the shape of the screws and screw-drivers, used plates made of bone, &c., with no particular advantage. As usual, the surgeon forgot the principle in detail. It is fortunate that in this form of surgery, unlike operations on the soft parts, the surgeon is able to show results capable of ocular demonstration by means of radiography, so that failures in procedure cannot be hidden as are so many others in surgery.

The difficulties experienced in dealing with recent simple fractures are trivial as compared with those which are met with in the restoration to their normal form of bones whose fragments have united in bad positions. In some cases the difficulties are quite insuperable. The skill and judgment required in old fractures of two bones such as the radius and ulna or the tibia and fibula may often be very great. A serious obstacle to union in old-standing cases results from change in the form of the displaced extremities of the fragments in the sclerosing process which they undergo. When gaps had to be filled up I employed in my earlier operations the bones of cats. These remained in position, acting as splints but apparently taking no active share in the formation of bone. Later I used pieces of bone cut from the fractured bone or from some other bone in the patient's body.

Most of the misfortunes which are met with in the treatment of fractures are due to the fact that the surgeon is satisfied to make an attempt to what is called "set" the fracture with or without an anæsthetic, not confirming the result of this process by radiography, too often with no advantage whatever to the patient. I have seen very many cases of fracture that have been put under an anæsthetic and have presumably been manipulated in some manner. The limb has then been put up in a splint and the patient assured that a perfect result would ensue. Many surgeons are wonderfully and unjustifiably optimistic in their prognosis of the results of the treatment of fractures by this method. In very few if any of the cases that have come under my observation have the fragments been replaced in position; indeed, as far as I could judge, in most of them little or no change had been effected in the relationship of the fragments to one another by the treatment to which they had been subjected. Of course it is quite open to anyone to say that the cases that came under my observation were exceptional, but I very much doubt it.

Another frequent source of trouble is that many radiograms taken at quite important institutions are worse than useless and afford very little accurate information. Too often they allow the surgeon to overlook injuries which are not clearly shown in them and to let matters drift till it is too late to interfere with the best advantage to the patient.

Obsolete Teaching.

Unfortunately much of the old and now scientifically obsolete treatment is still in common use even in our large teaching hospitals and in general practice, in consequence of which, in my opinion, no class of case receives worse treatment than do simple fractures. In my earliest paper I asserted that "the treatment of fractures as it exists at present is a disgrace to surgical practice," and now I have little hesitation in repeating the statement. This is so well recognised by the more intelligent practitioner that he regards a fracture as a most undesirable case, feeling that, through no fault of his own, he may be dragged into a court of law and mulcted in heavy damages. It has been my good fortune on several occasions to have been able to dissuade a patient from taking action against his medical attendant for the result of a fracture treated. I regret to say, too often very carelessly. Radiography has placed a powerful weapon in the hands of our patients, and in time they will be less easily satisfied. My experience would suggest that, except in the hands of a very few expert surgeons, little improvement has taken place in the treatment of fractures in spite of the advantages afforded by radiography.

The blame for all this does not lie with the practitioner but with the surgical staffs of the large teaching institutions; this is aggravated by the absence of any efficient training of the students in mechanics. The mode of teaching the mechanics of the skeleton and soft parts is most defective. While endless time is spent in the study of minute details in the structure of the several parts of the body, usually of no practical importance to the practitioner and therefore fortunately soon forgotten, the business or function of the component parts of the most elaborate mechanism of the human body, complex when normal but vastly more intricate when its form and function are modified by injury or disease, is treated most casually or often incorrectly, or it is completely neglected. On looking back at the amount of useless rubbish that comprised one's so-called medical education one is amazed that it should still continue.

A SILKWORM-GUT HOLDER.

To the Editor of THE LANCET.

SIR,—Everyone familiar with casualty work knows the need of a silkworm-gut holder which will deliver each piece separately. The following simple device has given every satisfaction. A lead weight is taken and two grooves are scored in it. A loop of stout silver wire is hammered into the grooves. The ends of the loop are bent and into these hooks is wedged the gut encircled by a rubber band. The elasticity of the rubber allows of each strand being drawn out singly. An elaboration of this idea, whereby plated steel hooks and an encased lead stand are used, is readily made at small cost by instrument-makers.

I am, Sir, yours faithfully,

A. P. BERTWISTLE.

Jan. 8th, 1923. R.S.O., General Infirmary, Leeds.

WELFARE WORK IN INDIA.

WELFARE work among industrial women and child workers is developing in certain parts of India. For instance, in Bombay City, in Ahmedabad, and in Sholapur, there are special medical dispensaries in the cotton mills for women workers and their children, under the care of women doctors or nurses. In addition, creches or day nurseries are organised in the mill compounds. In certain mills, in addition, a scheme of maternity benefit has been established. At Nagpur, sewing classes and health talks are held for the mothers in the intervals of their work, and a midwifery service has been started. In certain cases special provision is being made for the wives of men workers, with the object of promoting settled labour conditions. Under the direction of the Welfare Organiser of the British Indian Corporation at Cawnpore, preventive medical work is carried on by a woman doctor and nurses. Infant welfare centres have been established at Bombay, at Delhi, at Madras, and Bangalore.

The need for further effort to advance industrial welfare is emphasised in a communication to the *Indian Medical Gazette* of November, 1922, by Dr. Dagmar F. Curjel, W.M.S. In each of the jute and cotton mills around Calcutta, a doctor-babu and a dispensary may be found, but relatively few women workers come for treatment and those only for accidents or general complaints. For the special diseases of women and young children hardly any relief is given. Midwifery cases are still conducted by the indigenous *dai* or untaught midwife. On the other hand, the appointment of a nurse in a jute mill has led to over 2000 visits from women workers and children in the first six months, and she has been able to persuade women who needed doctor's treatment to come with her to the mill doctor. Dr. Curjel pleads for the establishment of nurse-midwives or health visitors, and the institution of creches. The cost, compared with the sums expended by mills on the sanitation of their compounds, would be small, and she considers it would be profitable expenditure.

The chief difficulty is in the matter of personnel, since rigid standards cannot be enforced and a wide tolerance, sympathy with native customs and prejudices, and experience of work in Indian cities are essential to success.

A SWEEPSTAKE FOR CANCER RESEARCH.

IN order to assist in the creation of a fund sufficiently large to enable the Hume-street Cancer Hospital, Dublin, to erect a research department, a sweepstake is being organised by Mr. P. L. Smyth at the hospital on the Lincoln Handicap, to be run on March 21st. Single tickets are priced 10s.; book of 12 £5. It is stated that each application will have an equal chance to win the prizes offered and at the same time help to investigate the cause and cure of this most terrible disease. The draw will take place at Hume-street Hospital on March 19th, at 3 P.M., under the supervision of the Hospital Committee and representatives of the press. A sum of £10,000 is to be divided in prizes, £5000 for the first horse. The Irish Government, in giving notice that sweepstakes are illegal and will no longer be tolerated by the police, has made exception in three cases, of which this is one.

Our Dublin correspondent writes: A month or two ago a sweepstake on a large scale was held in aid of one of the hospitals of Dublin, and several other hospitals have announced sweepstakes to be held in their support. It appears that the modus operandi is that a bookmaker or other financier gives guarantee for certain prizes and also for a considerable sum to be devoted to the funds of the particular charity concerned. He then promotes the sweepstake and any profits accruing over and above the guaranteed sums, and the necessary expenses, are his own. It is clear that with a well-organised and well-advertised sweepstake the profits may become far greater than the sum guaranteed to the hospital. Such sweepstakes are, of course, in contravention to existing law, but in the case of recognised and reputable charities the Irish Government has up to the present not put the law in force. Last week, however, the Minister for Home Affairs stated to Dail Earann that with the exception of the sweepstakes for which permission had already been given, the law would in future be strictly enforced. It is understood that certain persons interested in the Dublin hospitals are endeavouring to persuade the Government to reverse their decision, but many of the best friends of the hospitals are not displeased that a system open to grave abuse is to disappear. It is hard for a hospital to justify selling the prestige of its position for ten or any number of thousand pounds in order to permit the promoters of the gamble to win as much again. It is right to say that the sweepstakes which have been held hitherto have been conducted with entire probity and every guarantee of good faith.

TRAFFIC DANGERS.

"A Rhode Hogg" sends us the following bitter epitaph from America:—

> Here lies the body of William Jay,
> Who died maintaining the right of way;
> He was right, dead right, as he walked along,
> But he's just as dead as if he'd been wrong.

Among the deaths reported during last year to the city coroner of Manchester, fatalities arising from accidents numbered 303; of these motors were responsible for 57, horses and carts for 8, tramways and railway each for 5. Falls accounted for 85 deaths. Doubtless carelessness on the part of pedestrians contributed to these accidents, but a certain minimum would seem unavoidable under present conditions. Blame is not always easy to apportion.

THE POWERS OF SHIPS' SURGEONS.

AT a recent inquest at Southampton on a steward who died in the *Majestic* from meningitis following an accidental fall down a companion-way, two other stewards stated in evidence that they thought the man should not have been allowed to go back to his quarters. He was taken to the ship's hospital just after the accident and was afterwards in the stewards' "glory-hole" for four days before being again taken to the hospital. Dr. J. C. H. Beaumont, surgeon of the *Majestic*, said that before meningitis was apparent the man insisted on going back to his quarters, where he was visited day by day. The ship's surgeon, he said, had no power to confine a member of the crew to hospital against his wishes, unless the man was insane or suffering from some disease dangerous to the community aboard, and in either of those events the surgeon had to ask the commander to give an order. "Accidental death" was the verdict.

A clinical note from Sunderland was unaccompanied by the writer's name or address.

F. C. asks for the name of a sound and simple book to give a young man about to marry who wants instruction on sex matters.

Enquirer.—We understand that the inhalation treatment of whooping-cough at the Beckton Gas Works has been discontinued, as the medical officer of the works finds that inhalation of formalin is more efficacious and can be carried out at home.

Scrape.—An order was issued on Feb. 9th, 1920, prohibiting the importation into the United Kingdom of shaving brushes manufactured in or exported from Japan. Anyone in doubt as to the cleanliness of a new brush might soak it for an hour in a warm formalin solution (two tablespoonfuls in half a pint of water), as suggested by the Ministry of Health.

Secondary Infections in Tuberculosis.—Dr. R. E. Wingfield writes to correct an error in his article under the above title in THE LANCET of Jan. 13th. The strength of formalin used for killing bacteria for the preparation of vaccines should read 0·1 per cent. instead of 1 per cent.

Messrs. Savory and Moore call our attention to the fact that in 1796, the year in which he first performed vaccination, Dr. Edward Jenner prescribed a digestive lozenge for the relief of heartburn and acidity, which is still prepared by them from the original formula.

A Lecture

ON THE

NEED FOR RESEARCH IN FRAMING TUBERCULOSIS SCHEMES.

Delivered at the Royal Institute of Public Health on Jan. 17th, 1923,

By S. LYLE CUMMINS, C.B., C.M.G., LL.D., M.D. N.U.I.,

DAVID DAVIES PROFESSOR OF TUBERCULOSIS, WELSH NATIONAL SCHOOL OF MEDICINE; PRINCIPAL MEDICAL OFFICER, WELSH NATIONAL MEMORIAL ASSOCIATION, CARDIFF.

Tuberculosis is not merely a pathological but a social problem of the first importance. Diagnose a man as tuberculous, and you raise at once questions that affect all his most intimate human relationships—marriage, parenthood, occupation, home, friendships, amusements, hopes, and desires. You place him, too, in a new relation to the State as one whose individual liberty may have to be curtailed in the interests of others, and yet to whom is due such public expenditure on special accommodation and treatment as his condition may demand. Clearly, then, the tuberculous patient ceases to be the concern of the doctor only; he also demands the attention of the lawyer, the economist, the administrator, and the philanthropist, but none of the latter can hope to deal successfully with the problems laid before them except in the light of well-informed and carefully thought-out medical advice.

Some Difficulties of Medical and Lay Coöperation.

This enforced coöperation between men of different training is a difficult matter, involving serious obligations upon both parties. The chief dangers which beset the layman are that, trusting to his legal acumen or business experience, he may fail to draw the line at problems beyond his ken, or may try to set off the opinion of one doctor against another; or that he may fail to distinguish between the value of advice tendered by medical men with general as opposed to special knowledge of the subject in hand. But there are even greater dangers in the path of the medical man called upon for advice; perhaps the greatest of all is that he may unwittingly pretend to knowledge that he does not really possess. When our lay colleagues turn to us for advice on administrative problems we sometimes give them as facts what are really no more than opinions; forgetting that we are dealing with persons who, not having had occasion to study such problems for themselves, may accept what we say not critically but literally. Then, when the progress of science leads us to recast our views, our lay colleagues, not unnaturally, regard us as very uncertain guides and may even revert to their own business experience as more likely to be of use. A witty Frenchman, discussing the question of the politician versus the professional soldier, is reported to have said, "La guerre est trop serieuse pour la laisser aux militaires." The general trend of medical opinion has so often proved wrong—as, for instance, in its early attitude towards Pasteur and Lister—that many would subscribe to the phrase "La santé est trop serieuse pour la laisser aux médecins." There is certainly some justification for such an epigram, yet its acceptance would be a national calamity. With each new discovery our profession becomes of more and more administrative importance. Every year the progress of medical science reduces the number of subjects with regard to which "opinions" have to do duty for facts. But in the sphere of tuberculosis, although so much is known, there still remains a vast field about which accurate knowledge is lacking, and yet as to which conflicting opinions are so tenaciously held by their exponents as to be almost creeds.

For this reason something in the nature of a "recessional" is wanted, a humble re-examination of the foundations of definite knowledge upon which tuberculosis schemes are or should be built; in order that we, as a profession, may speak with the force of unanimous conviction where this is justifiable, and may agree to qualify our opinions as tentative only where finality has not yet been reached.

Infection and Resistance.

Let us first examine critically our knowledge as to the two fundamental factors that underlie tuberculosis—infection and resistance. What do we know about infection? We know the causative organism and how to cultivate it; we know many of its properties—vital, physical, and chemical, and we think that we know its varieties. But how many important details about its invasive mechanism still remain unknown! Fishberg, after a survey of the evidence relating to infection, is obliged to conclude that "there is no agreement among authorities as to the most common channel of entry of the tubercle bacilli before causing phthisis," and Römer is quoted by Fishberg as saying that "there is evidently some mode of transmission of this disease with which we are not as yet acquainted."

While these quotations serve to show how far from dogma are those who have spent their lives in the study of this disease, the fact remains that, apart from the question of the exact *mechanism* of infection, close contact with open cases is the outstanding source of danger to the healthy—a fact which no tuberculosis scheme in this country fails to recognise as of vital importance. There is, however, one aspect of the question which is too little considered and as to which more exact knowledge is urgently needed. To what extent does phthisis depend on reinfection from without?

This question, about which sharp differences of opinion exist, is of fundamental importance in administrative schemes. Was Hamburger right when, in 1912, he expressed the view that phthisis is an exacerbation of tuberculosis which was acquired during early childhood and remained latent for many years until some exciting cause or a reduction of the powers of resistance has brought about conditions favourable to its development? Or was Much correct in asserting that "a tuberculous organism is not susceptible to, in fact is immune against, superinfection from without?" There can be no doubt at all that, in these islands, the majority of those who after enjoying average health develop phthisis in middle or late adult life were already infected during childhood. The question is whether their phthisis is due to a reawakening of the old infection or to a fresh infection from without.

The importance of this question lies in its application to the prevention of the disease. If Hamburger and Much and those who think with them are right, it is clear that we may practically ignore the possibility of reinfection in adults and concentrate on obtaining for them such favourable conditions of life as will save them from a reduction in resistance. If, on the other hand, these careful observers are wrong, we may have to pay a great deal more attention than we do at present to the phthisic who, as the result of treatment provided by the State, is able to return to work as a clerk, a teacher, a butcher, a 'bus-conductor, or some such occupation.

Reinfection from Without.

In support of the theory that reinfection from without is unimportant is the fact that physicians and nurses are not more liable than others to tuberculosis; that marital infection is infrequent; that, in armies in the field, from the ranks of which infective persons have been carefully excluded, the incidence of pulmonary tuberculosis continues much as in the industrial life of peace time; while fatigue, poverty, excesses, child-birth and overwork, factors that operate against physiological well-being or involve physiological stress, are found to be constantly associated with a high phthisis mortality. Against this theory are the experimental findings in animals which prove that reinfection, though difficult, is possible, and that the immunity acquired through infection, though quite definite, is transitory. There is the fact, too, that although infection with the bovine bacillus is common in early life, it is hardly ever found in the phthisis of adults. The high incidence of the disease amongst clerks, domestic servants, and other persons liable to close contact with strangers who may be tuberculous, suggests that reinfection from without must frequently occur.

The evidence suggests that reinfection from without, though much more difficult than primary infection, is not only possible but frequent; that slight reinfections are readily overcome; but that repeated and massive reinfections are very serious, especially for those whose initial infections have been small, infrequent, and remote in point of time. But this is merely an expression of opinion, based on experiments and statistical data which, though suggestive, are not conclusive. Only successful research can give us the unanimity which is required if we are to tender advice of real utility on this subject.

Variations in the Clinical Picture.

Then, again, there is the question of the variations in symptomatology in the course of infection. With the same germ infecting the same species of host, it might be expected that the clinical picture would be fairly constant. As a matter of fact, in no disease is the clinical picture more diverse. It is certain, as pointed out by Krause, that some of the clinical variations are due to accidental factors, such as the location of tubercles close to large vessels or air passages; but it is equally certain that in every case the broad outlines of the clinical picture will depend upon the stability or instability of the balance between infection and resistance from day to day.

But what is the nutritional machinery that, inside these wide physiological variants, determines in any given case the state of the patient? There are physiological secrets behind the phenomena of nutrition which invite research, and the conquest of which may perhaps have great importance in treatment. The list of what we do not know about infection might be greatly prolonged, but as time is short I desire to pass on to some of the lacunæ in our knowledge about resistance.

Problems of Resistance.

It is common knowledge that the population of these islands presents marked individual variation in the power of resisting tuberculous infection. Some attribute this to differences in inherited susceptibility, others to variations in diet leading in certain areas and in certain strata of society to a food-deficiency favourable to tuberculous infection; while an increasing number of investigators tend to the view that the factor of most importance is variation in the degree of acquired resistance to the germ. While it is greatly to be desired that all these paths of investigation should be followed, there can be no reasonable doubt that civilised man owes to his powers of acquiring a relative immunity to the tubercle bacillus the steadily falling death-rate from tuberculosis which is such a marked feature of the recent history of human aggregations in Europe and elsewhere.

There is, however, one aspect of the question on which more definite knowledge is urgently wanted: The question whether the ingestion of milk infected with bovine tubercle bacilli plays a rôle in vaccinating us against human tubercle bacilli. Discussion of this question is often burked by the fear that expressions of medical opinion in favour of the theory of immunisation by infected milk may be exploited by interested persons to hinder progressive milk legislation. This seems an inadequate reason for avoiding a question of such vital importance. What evidence, if any, can be adduced in favour of this theory? It was proved 20 years ago by Von Behring and others that inoculation with living human tubercle bacilli could confer on calves a high degree of immunity to subsequent inoculation with a large dose of virulent bovine bacilli; and Calmette and Guérin proved that young calves could be immunised against the introduction of virulent bovine bacilli per os by previous feeding with appropriate quantities of human tubercle bacilli. It is therefore not unreasonable to surmise that the swallowing by children of milk containing living bovine bacilli confers on them some degree of resistance against human tuberculosis.

Since the only conclusive experiment is denied us, at least for the time being, we are obliged to seek for evidence of another kind: that provided by epidemiological investigations throughout the world. Here we find that it is universally true that where tuberculosis in cattle is absent or rare the inhabitants show a marked susceptibility to the human tubercle bacillus. This argument is not conclusive, because in just those same areas where bovine tuberculosis is rare, human infection, too, is uncommon, and so it may be that the immunisation due to minor infections with the human bacillus is wanting. Still, some of the instances that come to mind are very suggestive. Powell, for example, in a recent paper throws much light on the tuberculosis of India and the marked susceptibility to phthisis shown by the natives, and he definitely suggests that this is due in part to the absence of bovine infection which might serve to confer a relative immunity. In Africa similar observations have been made, and even in this country J. Brownlee has proved that the "young adult" type of mortality tends to coexist with a low percentage of infected milks. Finally, there is the vast natural experiment afforded by a community in which both bovine and human infections are common. Surely it only requires statistical research on a sufficiently comprehensive scale, and with sufficient regard to the reliability of the data collected for examination, to give us a final answer on this subject? The work of Riviere and of McNeil has already gone far to justify the conclusion that bovine infection does in fact protect; but the question is too important to allow of anything but a completely definite finding. Until this point is so completely cleared up that the medical profession accepts the conclusion with the same unanimity with which it accepts Koch's bacillus, we shall still be short of essential knowledge for the formulation of our tuberculosis schemes.

In conclusion, there remains the question, so vital to a colonial empire such as ours, of the epidemiology of tuberculosis amongst the inhabitants of isolated communities whence we draw recruits for our native regiments and for the industrial enterprises of our colonies and protectorates. We have at our disposal indisputable evidence of the extreme susceptibility of many of the races and tribes of our Dominions, but how much research can we quote as to the factors underlying this want of resistance? Surely it is worth while to invest large sums of money in the investigation of a problem which may mean life or death to tribesmen who look to us for security and protection, while we look to them for the personnel of our industrial developments throughout the Empire. The opportunity for this urgently needed research will soon pass with the increasing penetration of Europeans into the remote parts of Africa and elsewhere; but the knowledge to be gained might serve not only to direct preventive schemes abroad, but to widen the basis of our knowledge at home.

Royal Sussex County Hospital.—Soon after the closing down of 125 beds on Oct. 1st last, owing to the difficulty in raising funds, a committee was appointed "to consider and advise as to obtaining fresh sources of income and increased economy of administration." Last year's income showed a deficiency of £7000 over expenditure. The committee invoked the assistance of Sir Napier Burnett, who last month spent considerable time at the institution. Sir Napier Burnett has submitted a long report to the committee, and the inquiries suggested by him are being pursued. The committee state that there is nothing in Sir Napier Burnett's report, whatever criticisms it may contain, which should deter the public from continuing and increasing the financial aid given to the hospital.

An Address

[ABRIDGED]

ON THE RELATIONSHIP OF MEDICINE AND TOXICOLOGY.

Presidential Address delivered before the Harveian Society of London, Jan. 11th, 1923,

By Sir WILLIAM WILLCOX, K.C.I.E., C.B., C.M.G., M.D., F.R.C.P. Lond.,
PHYSICIAN TO ST. MARY'S HOSPITAL.

[The lecturer began by tracing the developments of medicine throughout the ages, associated with the work of the protagonists from Hippocrates down to Lister and Pasteur, showing the results of the application of chemical, physical, and biological researches to the elucidation of medical problems. And continued :—]

The Development of Toxicology.

The recognition of the deleterious qualities of poisonous plants and of the bites of venomous reptiles must have been recognised by prehistoric man at a time long antedating the historical period. The earliest writings indicate that the ancient Egyptians and the Hindus were well acquainted with the use of poisons. A translation of an early Egyptian papyrus in the Louvre says, "Speak not of the name of Yao under the penalty of the Peach," from which it is to be inferred that the Egyptian priests were familiar with the preparations of hydrocyanic acid from peach leaves and kernels. Homer relates that Ulysses sought to obtain from Ephyra a poison with which to anoint his arrows, and the word toxicology owes its derivation from this use of poisons (τόξον, a bow). Xenophon, 410 B.C., relates that the use of poisons was so frequent amongst the Medes that it was an ancient custom for the cup-bearers to taste the wine before presenting it to the king. The "History of Plants," written by Theophrastus, 300 B.C., contains many references to the poisonous as well as the medicinal action of the vegetable poisons. Hemlock was used by the Greeks for the execution of criminals, and was the cause of the death of Socrates, 339 B.C.

The search for antidotes was probably coeval with the discovery of the deadly effects of poisons, and the antidote discovered by Mithridates in the first century B.C. may be mentioned. Criminal poisoning is referred to in Roman History in 331 B.C., when about 20 matrons were surprised in the act of preparing a poison which they were compelled by the magistrates to drink and from which they perished. Roman law, 82 B.C., contains a legislative enactment dealing with the crime of poisoning, and a later enactment dealt with the use of poisons to procure abortion. It is recorded that Agrippina and her son Nero made elaborate studies in experimental toxicology upon the human subject, and applied this knowledge to the removal of several noted personages by poison. During the next thousand years the use of poisons was practised, but no great developments in toxicological science took place. Numerous deaths by poison of emperors and ruling sovereigns are recorded.

With the Renaissance in Italy poisoning became a fine art. Political murder by poison was considered to be quite legitimate in Italy, as is evidenced by the secret archives of the Council of Ten at Venice A.D. 1400 to A.D. 1500. Pope Alexander VI. and his son Cæsar Borgia committed numerous murders by poison. At least five cardinals were poisoned between 1495 and 1503 to satisfy the rapacity of Pope Alexander VI., who himself fell a victim by poison in 1503, his butler giving him the poisoned wine intended for one of his victims. Poisoning in England was not unknown at this period, and in 1531 a statute of Henry VIII. ordered poisoners to be boiled to death. Up to the nineteenth century criminal poisoning was very common, and probably preparations of arsenic and corrosive sublimate were most commonly used.

The methods of detection of poison depended mainly upon the circumstances attending the administration. The post-mortem appearances in cases of poisoning appear to have been little understood, and importance was attached to signs such as lividity, incombustibility of the heart, &c., which we now know to be not in any way characteristic of death by poison. As in the case of medicine, toxicology did not make any really great advance until the development of modern chemistry and its application in the laboratory to the solution of the analytical problems with which toxicology is bound up. It has been truly said that the only certain sign of poisoning is the identification by analysis of the poison in the body.

Outstanding Events in the History of Toxicological Chemistry.

The following are outstanding events in the history of toxicological chemistry: The discovery of the Marsh test for aresenic in 1836. The detection of arsenic in the liver, spleen, kidneys, heart, and muscle of a case of suicidal arsenical poisoning in 1839 by Orfila showed that poisons should be sought for not only in the alimentary tract, but in other parts of the body. The importance of the absorption of poisons was thereby appreciated. In 1844 Fresenius and Von Babo devised a method for the systematic search of all mineral poisons and for the destruction of the organic matter of the viscera as a preliminary to the analysis. In 1850 Stas discovered a process by which alkaloidal poisons could be extracted from viscera, and this in a modified form is in use at the present day.

Notable Trials Illustrating the Advance of the Science.

A study of some of the notable poisoning trials during the past hundred years gives a very good illustration of the advances made in toxicological science and of the precision with which it can be proved beyond all possibility of doubt that death must have been caused by poison. The trial of Dr. Palmer in 1856 is of great interest; Palmer was convicted of poisoning his victim, Mr. Cook, by strychnine. Dr. Alfred Taylor, author of the well-known work on jurisprudence, attributed death to strychnine, and formed this opinion on the clinical symptoms preceding death. He was unable to prove from his analysis the presence of strychnine in the body, and attributed his failure to detect the poison to the imperfection of the methods of analysis at that time, showing that when he poisoned rabbits with strychnine he was not always able to demonstrate the presence of the poison by toxicological analysis. No less than 15 medical men gave evidence in this trial, seven of them for the defence. In spite of the great dispute concerning the toxicological evidence, Palmer was found guilty. The case is remarkable, since a conviction for poisoning by strychnine was obtained in spite of the absence of proof by the Crown of the presence of strychnine in the body of the deceased. At the present day the proof of a poison like strychnine in the dead body would probably be necessary for a conviction to be obtained of death from strychnine poisoning.

In the trial of Madeline Smith, 1857, who was condemned to death for poisoning her former lover by arsenic, there was an array of expert toxicological evidence, and Prof. F. Penny, of Glasgow, performed a masterly analytical investigation which for skilful care and thoroughness would be all that would be required for a similar trial of to-day.

The trial of Dr. Pritchard in Glasgow, 1865, is of great interest. I know of no case where there is such a combination of heartless cruelty and smug respectable hypocrisy. Dr. Pritchard was slowly poisoning his wife with tartar emetic while evincing the most affectionate solicitude for her sufferings, when his mother-in-law arrived to assist in the nursing. Her efforts were rewarded by a combination of tartar emetic and tincture of aconite which proved fatal, and a few days later the unfortunate wife succumbed to the long course of tartar emetic which had caused untold suffering. The analytical investigations in this case were undertaken by Prof. F. Penny and Dr. Douglas Maclagan. They formed a masterly piece of work, carried out with care and skill which could not be surpassed to-day. This case is remarkable since aconitine was clearly proved to be present in the body of the first victim, and quantities of antimony beyond that of a possible fatal dose were demonstrated in both victims. The detection of aconitine at that time reflects the greatest credit on the scientific skill of the investigators.

The trial of Dr. Lamson, in 1882, was of interest, since the subtle poison aconitine, for which no definite chemical tests were known, was the cause of death. Sir Thomas Stevenson, by his masterly toxicological analysis, succeeded in extracting the poison from the viscera and proving its presence by physiological tests on himself and on mice. He gave incontestable proof that a poisonous dose had been taken, and Lamson was duly convicted of murdering his wife's nephew, Percy Malcolm John, aged 18, from whom he would have inherited through his wife a large sum of money.

The Maybrick trial aroused great interest in 1889. And here Sir Thomas Stevenson again performed a brilliant toxicological analysis. Mrs. Maybrick was convicted of poisoning her husband by the administration of arsenic. The interest of this case lies in the fact that the proof of fatal poisoning rested on the presence of $\frac{1}{3}$ gr. of arsenic in the liver, the minimum fatal dose being about 2 gr. The defence maintained that arsenic might lie in the liver in islands, not being uniformly distributed, and disputed the calculation by which, on the quantity found in a portion of the liver, the estimation of $\frac{1}{3}$ gr. for the whole liver was based.

The trial of H. H. Crippen, 1910, was of interest because this was the first case in which hyoscine had been used as a poison in a fatal criminal case. In this case the poison was extracted in spite of the burial of the viscera for six months, and the presence of hyoscine was clearly demonstrated by chemical tests and by its mydriatic action on the cat's eye.

The trial of the Seddons was of interest because in this case arsenic was found in all the organs of the victim, Miss Barrow, and a computation of the total amount of arsenic in the body was made by a determination of the arsenic present in each organ. The corpse was actually weighed for this purpose, as well as the individual organs. A fatal poisonous dose of 2 gr. was proved to be present in the body. For the purpose of this analysis the electrolytic Marsh-Berzelius test was used for the first time in determining quantitatively the amount of arsenic in each organ.

The Black case, 1922, was a very interesting case of arsenical poisoning. Although arsenic was present in appreciable amount in all the organs, the total amount found in them was considerably less than a possible fatal dose. The explanation of the small amount of poison in the body was clearly shown by the clinical history. The case was one of delayed arsenical poisoning, a considerable proportion of the arsenic having been got rid of by excretion in the few days which elapsed between the administration of the poison and the time of death.

The Armstrong case was a clear case of acute arsenical poisoning. The interest of this case lies in the fact that arsenic would have never been suspected as the cause of death in Mrs. Armstrong, who had died about a year previously, unless Major Armstrong had attempted to poison his rival solicitor, Mr. Martin, by arsenic. The discovery of arsenic as the cause of Mr. Martin's illness was made by the analysis of Mr. John Webster of the urine passed by Mr. Martin three days after the poison had been taken. The advantage of toxicological research is here beautifully illustrated, for the knowledge of the rate at which arsenic is excreted after a possible fatal dose has been taken enabled the deduction to be made that Mr. Martin must have been given a fatal dose of arsenic.

The Armstrong case and the Black case both illustrate the effect of imitation in the causation of criminal poisoning. It cannot be doubted that the sensational reports of a noted case of arsenical poisoning (the Greenwood case) led to the selection and use of this poison in these two cases. I will conclude by giving a brief account of a case of arsenical poisoning which came to my notice a few days ago.

A Government official in a tropical country consulted me on account of an illness which had given rise to much difficulty of diagnosis. On Oct. 6th, 1922, he was attacked with severe abdominal pain, vomiting, and diarrhœa, watery stools containing some mucus being passed. He was very ill with these symptoms for three days and a good deal of hiccough occurred. On the 9th circumoral herpes developed. The patient remained in hospital until the 30th, when he returned to duty. He now began to suffer from slight cramps in the feet, some numbness and feeling of coldness in the hands and feet, and some weakness of the legs. Marked thickening of the skin of palms and soles occurred, and the skin peeled off here in the middle of November. In consequence of these symptoms the patient came home in November, and he consulted me on Dec. 19th, 1922. Slight anæsthesia to a light touch was found in the hands and feet, and some thickening of the skin of the palms and soles was clearly present. The patient consented to some of his hair being removed for purposes of analysis, and Dr. Roche Lynch kindly submitted this to the electrolytic Marsh-Berzelius test. A considerable amount of arsenic was found in the hair, $\frac{1}{22}$ of a milligramme in 3 grammes of the hair.

The diagnosis in this case was clearly that of acute arsenical poisoning on Oct. 6th, 1922. In reply to my question, the patient told me that there had been considerable trouble on the 6th, on account of the misbehaviour of his native cook, who was discharged from service on the following day. The explanation of the source of the arsenical poisoning does not appear difficult of comprehension. This case is of great interest, since by reason of the knowledge of the mode of excretion of arsenic a diagnosis of acute arsenical poisoning can be definitely made as long as ten weeks after the poison had been administered.

ADVANCEMENT OF KNOWLEDGE DURING THE WAR.

As a result of the war our knowledge of toxicology has become greatly increased. The use of tetrachlorethane in the manufacture of aeroplanes led to the occurrence of a number of cases of toxic jaundice, and it was the toxic action of this poison on the liver which caused degeneration of the liver cells and jaundice. In some of the severe cases death occurred from icterus gravis, the post-mortem appearances being those of acute yellow atrophy. Poisons used as munition explosives, such as tri-nitro-toluene, di-nitro-benzene, picric acid, &c., produced toxic jaundice in a precisely similar manner. The jaundice following the use of arsenobenzol derivatives has, during and since the war, been of very common occurrence. It is a toxic jaundice precisely similar to that occurring from tetrachlorethane and other similar poisons.

The discussion at the British Medical Association meeting in Glasgow, July, 1922, on Degenerative Diseases of the Liver, amply illustrated the close and important relationship between toxicology and medicine. Indeed, much of our recent advance in knowledge on liver diseases and hepatic function has arisen in consequence of the toxicological studies of the action of various poisons on the liver.

Numerous other instances might be cited of the great value of toxicological research not only in toxicology, but in the advancement of the knowledge of the function of organs and the action of drugs. Toxicology, like medicine, owes its great advances during the past hundred years to advances in scientific knowledge and the gaining of detailed and accurate information by experimental observations in the laboratory. The close coöperation of the physician, who carefully observes the clinical toxic effects of poisons, with the toxicological chemist, who conducts in the laboratory the fullest analytical investigations, will produce the highest results in this important branch of biochemistry and medicine.

DIASTASE IN BLOOD AND URINE AS A MEASURE OF RENAL EFFICIENCY.

By G. A. HARRISON, M.B., B.Ch. Camb.*

and

R. D. LAWRENCE, M.D. Aberd.†

(*From the Biochemical Laboratory, King's College Hospital, London.*)

The concentration of urinary diastase has been widely used as a test of both pancreatic and renal efficiency. Comparatively few investigators, however, have estimated the blood diastase, and even fewer have determined simultaneously the values for blood and urine. Particular attention has therefore been paid to these points. The estimations in urine have been made by Wohlgemuth's method, and in blood by the same method or by a "drop" modification, mentioned below.

Corbett (1913) used a Wright's pipette with a fiducial mark to measure the unit volume of serum. At the suggestion of Dr. E. ff. Creed we have employed dropping pipettes of the pattern used in Dreyer's method of estimating agglutinins. Corbett found "there was no practical difference in the results, whether equal volumes of serum were digested with increasing volumes of starch, or whether equal volumes of starch were used with decreasing volumes of serum." Our experiments confirm this statement. Twenty-three samples of blood have been estimated with identical results by the two methods. One drop of serum is placed in each of a series of tubes and 1, 2, 3, &c., drops of 0·1 per cent. soluble starch in 0·5 per cent. sodium chloride (see Cole, 1920) are added. For values above 20, a preliminary dilution of serum 1 in 10 with 0·9 per cent. saline is made. The following advantages are claimed for such a method: (1) Very small quantities of serum (less than 1 c.cm.) are required, thus allowing repeated observations on the same patient. 2. The diastatic index can be easily estimated to a single unit; the result is recorded in whole numbers; the decimal places recorded by the ordinary method give a false idea of its accuracy. 3. The tests can be set up very rapidly. 4. No calibrated pipettes or burettes are required. 5. The use of a teat removes all risk of contamination with saliva.

Preliminary Experiments.

(*a*) *Plasma and Serum give Identical Results.*—Corbett (1913) found "that the values obtained from the serum were a little higher than those from the plasma." To test this point blood was obtained from 25 patients, and each sample was divided into two; serum was prepared from one, and oxalated plasma from the other, and the diastase content of each was determined. In every instance the plasma gave the same result as the serum.

(*b*) *Blood Diastase Remains Constant Throughout the Day.*—A healthy active individual and a patient with mild diabetes mellitus were bled every hour for eight hours. The first estimation was made after a night's starvation, and two subsequent meals gave ample opportunity for observing any effect due to intake of food and digestive activity. In both individuals, however, the serum diastase remained absolutely constant. Two patients with diabetes mellitus were tested at intervals of 30 minutes for two hours, and four diabetics and two healthy students at intervals of 60 minutes for three hours. The maximum variation in diastatic index in any individual in this series was one unit. For clinical purposes, therefore, it is sufficient to make a single estimation of blood diastase at any time of the day. Furthermore, it is justifiable to compare the result of such an estimation with the diastatic index of the 24 hours' urine.

Cammidge (1920) states that in diabetes the serum diastase rises with increase of blood-sugar. We have been unable to confirm this on any given day, and have found practically no alteration in diastatic index even when the blood-sugar is doubled. This discrepancy may be due to the fact that Cammidge estimates blood diastase by the amount of sugar produced by the enzyme from a known quantity of starch, and therefore his results are not strictly comparable with ours. We have, however, occasionally observed slight variations in estimations made at intervals of several days in diabetes, but have found no constant parallelism between the concentration of diastase and the percentage of sugar in the blood of such patients.

Results in Normal Individuals.

The blood diastase of 24 healthy active individuals varied between 3 and 7 units, with a mean of 4·4. The index of 23 convalescent hospital patients, confined to bed for the greater part of the day (excluding diabetics and cases recovering from diseases of the pancreas, liver, or kidney), varied between 3 and 10 units, with a mean of 6·5. A blood diastase above 10 or below 3 may therefore be regarded as abnormal. Wohlgemuth and Noguchi (1912) gave 8 to 16 as normal for serum; Corbett (1913) found an average of about 10, and Stocks (1916) 6·7 or 8. Maclean and de Wesselow (1919) found an average diastatic value of 5 to 10 in plasma.

Our urinary findings agree with those of other investigators: 6·7 to 33·3 units for specimens of the 24 hours' urine. In every case the urinary index has been higher than that of the blood. Stocks (1916) found that the total diastase excreted per diem, M (the product of the diastatic index and the volume in c.cm. of the urine in 24 hours), was a useful check upon d the concentration of diastase, revealing those instances in which low or high values for d might legitimately be attributed to diuresis or oliguria. We have similarly found M useful, but would give 8000 to 30,000 as the normal range, instead of 10,000 to 15,000. All our specimens of urine have been collected under toluene.

Renal Disease.

The results of diastase tests in 43 cases of kidney disease may be divided into three groups: (*a*) "Diminished excretion with retention," in which the value for blood is above 10, and for urine below 6·7 (6 cases). (*b*) "Diminished excretion without retention," in which the blood amylase is within normal limits, but the concentration in the urine is lower than in the blood or of the same value (17 cases). (*c*) "Normal excretion" in which d is higher in the urine than in the blood (20 cases). Examples of the three groups are given in the table. By comparison with the urea and other tests of renal efficiency we conclude that diastase retention only occurs when at least three-quarters of the total kidney substance has been thrown out of action. Group (*c*) includes kidney lesions ranging in severity from "slight" to "moderately severe." Group (*b*) embraces cases which, on the whole, are more severe than those in group (*c*), but not such extreme cases as in group (*a*) in which probably less than one-quarter of the total kidney tissue is functioning.

---

* Work to be included in a report to the Medical Research Council.

† Results embodied in a thesis for the Degree of Doctor of Medicine, Aberdeen, 1922.

As controls we have examined the urinary and blood diastase in a variety of diseases, in all amounting to 180 cases. "Diminished excretion with retention" has never been encountered except in severe renal conditions. On the other hand, "diminished excretion without retention" has been found in two patients with hepatic disease, seven with diabetes mellitus, three with pernicious anæmia, one with gastric ulcer, and one with gastric carcinoma. In none of these 14 patients was there evidence of kidney disease clinically, or by renal function tests. We conclude that when a subnormal concentration of urinary diastase (allowing for diuresis if present) is accompanied by a raised concentration in the blood, there is severe renal damage; but that a low *d* value in the urine is not in itself evidence of renal disease. From a study of examples of low urinary amylase we suggest that "diminished excretion without retention" results from a lessened formation of the ferment in the tissues, due either to a general depression of metabolism, or to low diets, or to both factors. Such a hypothesis is by no means at variance with the comparative frequency of "diminished excretion without retention" in kidney disease (17 out of 43 cases).

404	30/7/21	3·3	20	960	19200	Prostatectomy; death in 36 hours from uræmia, 10/8/21.

* Calculated to the nearest hundred.

In one case (K 404) the diastase tests failed to reveal a very extensive degree of renal damage. The patient died from uræmia 24 hours after prostatectomy. His diastase in both blood and urine was normal, but the urea-concentration test gave a result of 1·55 per cent., and one physician considered him uræmic on clinical grounds before the operation, although the surgeon was not of that opinion. The case illustrates the necessity of weighing up all the evidence, clinical and laboratory, in assessing renal efficiency. Case K 210 is particularly interesting. There is a low urinary diastase throughout, but the blood *d* varies greatly. At first it is normal (29/4/21), but later there is definite retention. The fluctuations in blood amylase are probably, in part at any rate, dependent on variations in the amount of œdema as a result of incising the feet. Clinically the patient became slowly but progressively worse.

In conclusion we have found estimations of diastase in both blood and urine of value in confirmation of other renal efficiency tests, but would never rely on an estimation confined to the urine.

Summary.

1. It is immaterial whether serum or plasma be used for estimation of blood amylase.

2. The concentration of the enzyme in the blood remains constant throughout the day.

3. Normally, values for blood lie between 3 and 10 units.

4. It is necessary to demonstrate retention of diastase in the blood before concluding that disease of the kidneys is responsible for a diminished excretion of the ferment.

5. Diastase estimations have been found useful in confirmation of other renal efficiency tests, but only in severe cases.

NOTE.—Since the above work was done it has been shown that estimations of urinary diastase may be affected by the reaction of the urine (THE LANCET, 1922, ii., 68; *Brit. J. Exper. Pathol.*, 1922, iii., 133). This may account for some of the cases with diminished excretion without retention, but not for all. At the time of writing only 30 urines have been tested after adjustment of reaction to pH 6·7, and the majority of these have shown an increase exceeding 20 per cent. A fair number, however, have not been increased appreciably after correction. There still remains a proportion of cases with "diminished excretion without retention" in both renal and non-renal diseases, for which reason the conclusions in the above paper still hold good.

GLUCOSE TOLERANCE IN CHRONIC ARTHRITIS *

AND ALLIED CONDITIONS.

BY G. L. KERR PRINGLE, *M.C.*, M.D. EDIN.,
HONORARY PHYSICIAN, ROYAL BATH HOSPITAL;
AND
S. MILLER, D.S.O., *M.C.*, M.D., B.SC. BELF., D.P.H.,
HONORARY PATHOLOGIST, ROYAL BATH HOSPITAL AND HARROGATE INFIRMARY.
(*From the Clinical Laboratory, Harrogate.*)

Pemberton and others[1] published in 1920 a series of articles bearing on 400 cases of arthritis in the American Army. Pemberton, dealing with the cases from the dietetic and laboratory sides, shows that in a considerable percentage of cases of arthritis there is a definite relationship between the intake of food on the one hand, and the incidence or perpetuation of the symptoms of the disease on the other. Of the three food-stuffs—fats, proteins, and carbohydrates—there is evidence that carbohydrates have the greatest influence on the perpetuation of symptoms. Hence, he determined to ascertain whether there was any difficulty in the metabolism of carbohydrates, and with this object he investigated in 60 cases of arthritis the fasting level of the blood-sugar and the response of these cases to the so-called glucose-tolerance test. It was evident from these investigations that sugar intolerance was increased in a very large number of cases of arthritis, and that—though the intolerance disappeared after the removal of the infective focus in a certain number of cases—the articular condition was not specially improved by the removal of the infective focus or foci, and did not markedly improve until the patient had been kept for some time on a diet in which the carbohydrates were very much restricted.

Object and Scope of the Investigation.

The object of the research here described was, if possible, to corroborate Pemberton's work in cases of arthritis occurring amongst the civil population, as contrasted with Pemberton's cases which were derived from picked young adults of the United States Army, in none of whom the disease could be termed very chronic. The research was undertaken at the Royal Bath Hospital, Harrogate, which, with the convalescent home attached to it, contains 150 beds practically all devoted to cases of arthritis. Hence the material for investigation was ample, and of necessity some choice had to be made, though the cases were not specially selected. We decided to examine 100 cases, and a limited number were taken from the admissions to the hospital each week.

The scope of the investigation was widened beyond the limits of Pemberton's work, as we decided that, in addition to the determination of the glucose tolerance in each patient, and the repetition of the test in the case of some of them after the removal of the infected foci, it would be advisable in as many cases as possible, to obtain blood cultures, ascertain the Wassermann reaction (W.R.), make bacteriological and short chemical examinations of the urine and fæces, as well as cultural examinations of other foci of infection, such as apically infected teeth, tonsils, nasal sinuses, &c., with the object of identifying otherwise undetected foci of infection. In this preliminary report we propose only to deal with the findings of the glucose-tolerance reaction and the biochemical and bacteriological examination of the blood, and reserve the cultural examinations of the urine, fæces, and foci of infection for a subsequent report.

Technique.

The estimation of the blood-sugar percentage was carried out in strict accordance with the method described by Prof. H. Maclean.[2] The glucose-tolerance tests were carried out according to the following procedure: The patient had a light supper the night before the test, and no food in the morning. On the day of the test, specimens of blood for the determination of the blood-sugar percentage and of urine for chemical analysis were obtained, and immediately afterwards 100 g. of glucose in 200 c.cm. of water were given. Half an hour after the ingestion of the glucose solution a second specimen of blood was taken. One hour after the ingestion of the glucose solution a third specimen of blood was taken and another specimen of urine. One and three-quarter hours after the ingestion of the glucose solution a fourth specimen of blood was taken. Two and a half hours after the glucose solution a further specimen of urine was taken, and in certain cases a further specimen of blood also.

Generally the test commenced at 8.30 A.M. The requisite amount of blood, 0·2 c.cm., is obtained from the lobe of the ear in specially manufactured pipettes, and diluted with 23·8 c.cm. of acid sodium sulphate solution in an Erlenmeyer flask. The mixture is then brought to boiling point over a guarded bunsen flame, the size of the flame being regulated by a manometer as per Maclean's method. 1 c.cm. of dialysed iron is now added slowly, the flask being shaken gently all the while. This completes the precipitation of all the protein material present in the blood. The mixture is then cooled and filtered through a starch-free filter-paper into a dry flask. The filtrate comes through the filter-paper as a clear crystalline fluid and perfectly free from protein; 20 c.cm. of this filtrate—i.e., four-fifths of the original 25 c.cm. of fluid—is taken, and the sugar present is estimated by boiling the liquid with a known excess of copper sulphate solution. The excess of copper sulphate is then estimated, and from this figure the blood-sugar percentage can be calculated. The method is accurate and consistent, as Table I. will show.

TABLE I.—*Results of Duplicate Estimations of Blood-Sugar Percentage in a Series of 12 Cases in Routine Laboratory Work.*

1	*2*	*3*	*4*	*5*	*6*
0·111	0·221	0·078	0·218	0·119	0·231
0·109	0·220	0·076	0·216	0·120	0·230
7	*8*	*9*	*10*	*11*	*12*
0·112	0·125	0·180	0·115	0·089	0·100
0·114	0·122	0·182	0·116	0·088	0·099

From the table it will be seen that the method gives consistent results with duplicate specimens of blood. The importance of taking specimens of blood for blood-sugar determinations at short intervals after the ingestion of the glucose solution should be emphasised, for in a large percentage of cases the maximum point on the blood-sugar curve is reached within the first hour, and in many cases the reading obtained after the first half hour is the only one which affords information regarding slightly lowered glucose tolerance. Many of the curves show a drop below the fasting level towards the end of the test. The other specimens—viz., the blood, urine, fæces, &c., for culture, and serum for the W.R.—were obtained at times most convenient for the patients, and were examined by the usual laboratory methods.

It was considered desirable that the whole investigation should be completed before any analysis of the results were made, and though this had many advantages, it deprived us of the opportunity of repeating observations in certain, though a very few, doubtful cases. There are many short-comings in the investigation, and we look upon it merely as a preliminary to further work which we hope to carry out this year and to continue at a future date. At the commencement it was hoped that the glucose-tolerance test might serve not only as a guide to diagnosis and prognosis, but also to furnish an index for the dietary of the patient. The rationale of a restricted diet in these cases can certainly be questioned, and it seems difficult to understand why the restriction of carbohydrate should influence the arthritic symptoms, especially when we know of the protein-sparing property of carbohydrate. The great loss of weight seen in certain of these types of cases would rather suggest that they were greatly in need of carbohydrate in increased quantities. In our further investigations we propose to try the effects of a restricted carbohydrate diet in certain types, which at present we will not define.

---

* An extract from a paper read before the Harrogate Medical Society.

To facilitate the analysis of this investigation it became necessary to try to arrange the cases of arthritis investigated under some classification which would be readily recognised. For this purpose we adopted a classification modified from one which had been used by one of us (G. L. K. P.) for some time, of which the groups and subgroups are as follows :—

Classification of Arthritis.

1. *Infective.*—(*a*) Arthritis associated with specific organisms (gonococcus, tubercle, streptococcus, malaria, &c.) ; (*b*) arthritis of unknown origin ; (*c*) arthritis in association with zymotic disease (scarlet fever, measles, &c.) ; (*d*) septic arthritis ; (*e*) rheumatic fever.
2. *Metabolic.*—(*a*) Gout ; (*b*) arthritis associated with deficiency of endocrine glands ; (*c*) scurvy, hæmophilia.
3. *Neurotrophic.*—Tabes, syringomyelia.
4. *Traumatic.*—(*a*) Injury (dislocation, loose bodies, sprains) ; (*b*) static (villous arthritis of Goldthwait, arthritis associated with flat-foot, coxa vara, knock-knee).
5. *Degenerative.*—(*a*) Senile osteoarthritis (morbus coxæ senilis, Heberden's nodes) ; (*b*) a sequela of traumatic, infective, and metabolic arthritis.
6. *Toxic.*—Anaphylaxis, horse serum, &c.
7. *Periarticular Fibrositis.*—Jaccoud's chronic fibrous rheumatism, chronic articular rheumatism.

Explanatory Notes on the Classification.

The term " associated with " is used in the infective group, as we recognise that the presence of an infective focus or foci is not conclusive proof that it is the only causal factor in the disease ; and one of the principal reasons this investigation was undertaken was an attempt to determine other causal factors that might be present. Arthritis " of unknown origin " is specially intended to refer to those difficult cases in which no infective focus has been found, which are polyarticular in character, occurring in young women and which tend to progress—i.e., true cases of " rheumatoid arthritis," a very small proportion of the cases of chronic arthritis.

This classification does not pretend to be perfect, but according to our present-day knowledge, it is as far as one can go, and it is essentially clinical in character. We have arranged the cases under this classification, and have divided them into nine groups. No doubt we have made mistakes ; there are several cases which, from a clinical point, we should like to review again.

The cases, arranged in tabular form, are given in Table II.

TABLE II.

Group.	Infective.				Metabolic.	Traumatic	Degenerative.	Periarticular fibrositis.	Muscular fibrositis.
	A.			B.					
No.	1*	2†	3‡	4	5	6	7	8	9
No. of patients	19	19	12	6	3	8	14	11	8

* Mild ; † severe ; ‡ arrested.

We see that 56 per cent. of the cases belonged to the infective group, 3 per cent. to the metabolic group, 8 per cent. to the traumatic group, 14 per cent. to the degenerative group, 11 per cent. to the periarticular fibrositic group, and 8 per cent. to the muscular fibrositic group. The infective group A we have divided into three subgroups—mild, severe, and arrested ; these subdivisions will be dealt with later in the paper. Table III. shows the method of setting out the principal findings and progress of each case investigated ; the whole series of nine groups was treated in this manner, but from considerations of space we include Group 1 only.

At the commencement of the investigation it was considered desirable that the glucose-tolerance response should be determined on a number of normal healthy individuals. The test was carried out with these subjects on similar lines to that already sketched out and the figures given in Table IV. were obtained.

From this table it is evident that the maximum blood-sugar percentage in a normal individual during a glucose-tolerance test falls below 0·17 per cent., and we have taken this figure as the dividing line between the normal and the pathological response. A blood-sugar percentage of 0·17 is generally accepted by most workers as the maximum limit for the healthy individual. It was hoped that something might have been gained by making graphs showing the variation of

ABBREVIATIONS.

Joints Affected : A., ankle ; E., elbow ; F., foot ; H., hip ; K., knee ; S., shoulder ; W., wrist ; P., polyarticular (used where three or more joints are involved).

Glucose-Tolerance Findings : Blood-sugar percentages (1) fasting ; (2) half an hour ; (3) 1 hour after ; and (4) 1½ hours after glucose meal.

Sugar Passed in Urine During Test : +, sugar in small quantities ; + +, moderate amount, up to 0·5 per cent. ; + + +, marked amount, over 0·5 per cent.

Degree of Intolerance : It is premised that when the blood-sugar percentage of the patient during the glucose-tolerance test rises to 0·17 per cent. or higher, there is present some glucose intolerance or a lowered glucose tolerance ; + denotes slight degree of intolerance (0·17 per cent. to 0·19 per cent.) ; + +, moderate degree of intolerance (0·19 per cent. to 0·22 per cent.) ; + + +, marked intolerance (0·22 per cent. or higher).

Blood Cultures : Negative denotes no growth after cultural examination.

TABLE IV.—*Glucose-Tolerance Tests on Normal Individuals.*

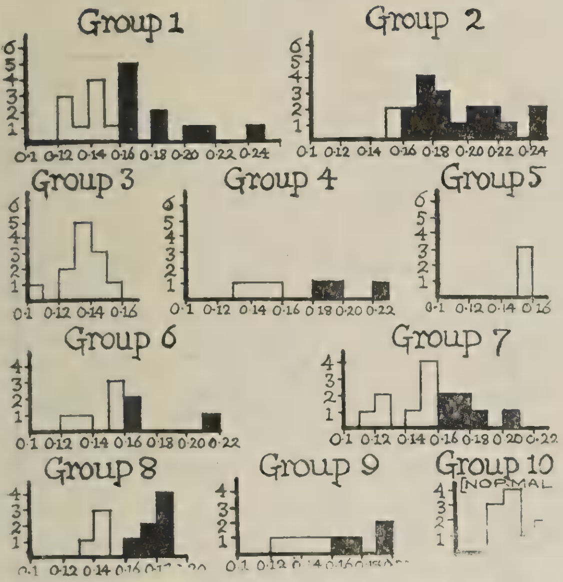
the blood-sugar with the duration of time elapsed since ingestion of the glucose meal. This method proved too cumbersome, and in its place we have plotted the highest blood-sugar percentage given by patients during the glucose tolerance test against the number of patients in each group giving that percentage. In this way an easy comparison can be made between the varying glucose tolerance responses of the cases in each group and between the groups themselves. (See Fig. 1.) Referring to these graphs it will be seen that in Group 1 the average maximum blood-sugar falls below the normal maximum range—i.e., below 0·17 per cent. In the large number of the cases the range of the blood-sugar percentages approximates very closely to normal. In this group only five cases show a blood-sugar higher than the maximum normal.

FIG. 1.



Blood-sugar percentages given by patients during the glucose tolerance test, and number of patients giving those percentages in the various groups. Shaded areas represent abnormal sugar tolerance (i.e., over 0·17).

It must be emphasised here that the glucose tolerance test is merely a ready method of ascertaining deviation of a function which is undoubtedly complex and dependent on many factors not fully understood. The way in which the height of blood-sugar curves are influenced by toxins is open to much speculation; for instance, the toxin may directly stimulate the action of the diastase of the liver and muscles, or it may inhibit their glycogenic power. Again, focal toxins may act on higher cerebral centres. Also the well-known protein sparing property of carbohydrate, especially in long-sustained fevers, suggests that carbohydrate is burned most readily, and, according to Olmstead and Gay,[3] is possibly "mobilised to protect protein." Hence, other factors besides the severity of the arthritic process may influence the response to the glucose meal. If we refer to the further progress of this group we find that there is marked improvement in six cases of the group, moderate improvement in ten cases, while in the remainder there is little or no improvement. Thus, in 85 per cent. of the cases of this group the condition of the patient has been improved by the removal of the infective focus, medicinal, hydro-, and electro-therapeutic measures including the use of vaccines in selected cases.

From Fig. 1 it will be seen that in Group 2 the average maximum blood-sugar percentage is 0·19, and that the majority of cases in this subdivision show a marked intolerance to the glucose meal. The further progress of these cases is instructive. In eight only has there been any moderate or marked improvement after prolonged treatment both at the Royal Bath Hospital and after return to their homes. This figure is a marked contrast with that found in the previous group, and emphasises the fact that a marked intolerance to glucose in a severe and actively progressing infective arthritic patient indicates a guarded prognosis. In some cases the termination may be fatal, as in one case of this series.

Group 3 is composed of a series of patients who might best be described as suffering from post-infective effects. The active infective condition in these patients appears to have been arrested, and the patients were suffering chiefly from the disabilities brought about by the disease, rather than the disease itself. As might be surmised, the average maximum blood-sugar percentage lies well within the normal range. No marked improvement was shown in any case of this series after treatment, though there was some alleviation of the disabilities through massage, ionisation, hot-air treatment, &c.

Group 4 contains cases considered to be infective in origin, but in whom no infective focus was found. These are the cases which we have already referred to, occurring in young women. Strangeways has recently, in a personal communication, expressed the view that this type of case never occurs in men, and though we have included one case of a male in this group, we are by no means certain that it should not have been included in the group of periarticular fibrositis. It must always be remembered that the problem of unearthing the infective focus is most difficult. Every avenue must be explored, and any additional aid in proving the presence of a focus is most valuable. In this group of cases the average maximum blood-sugar percentage during the glucose tolerance tests falls above the average maximum normal range.

Group 5 includes only three cases—all of arthritis due to derangement of metabolism—i.e., gout. The blood-sugar percentage in this series falls within normal limits. In Group 6 the average maximum blood-sugar percentage falls within the normal range. In Group 7 the infective element may be considered as largely in abeyance. The average maximum blood-sugar percentage during the glucose tolerance test is 0·157 per cent., and this lies within the normal range. In Group 8 the average maximum blood-sugar percentage during the glucose tolerance tests lies slightly above the average normal limit. This fact is consistent with the accepted opinion that many fibrositic conditions are infective in origin. Group 9, which includes those cases allied to arthritic conditions—viz., muscular fibrositis, is very similar to Group 8. Undoubtedly many cases of muscular fibrositis have their origin in some infective focus or other.

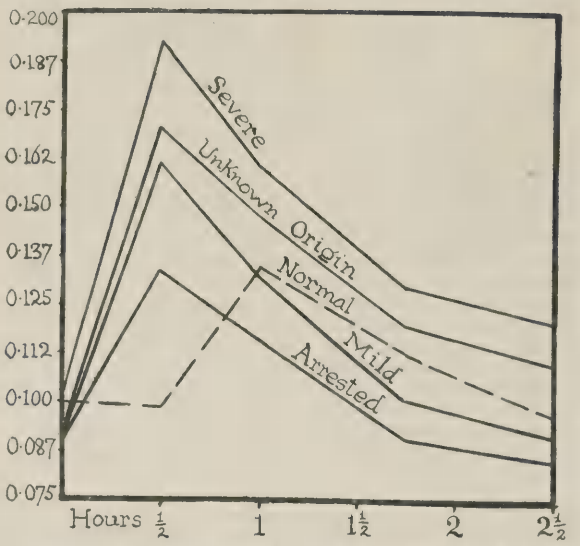
Group 10 comprises a series of maximum blood-sugar percentages in ten normal subjects during glucose tolerance tests; the average height in these ten cases is 0·135 per cent.

A survey of these graphs will bring into prominence the marked variation in the maximum blood-sugar percentages in cases of infective arthritis of varying severity. In Group 1 there is little departure from the normal glucose curve, while in Group 2, the severe cases of this sub-group, the departure is most marked. Again, in Group 3, the "arrested" cases of the sub-group, the glucose tolerance tends towards a normal figure. The remaining graphs showing departure from the normal represent the group of "infective cases of unknown origin" and the two groups periarticular fibrositis and muscular fibrositis.

In general it may be said that the height of the blood-sugar curve in the glucose tolerance tests in arthritic cases is largely proportional to the activity of the arthritic processes. Further, we are of the opinion that the severity of the arthritic process per se varies directly as the activity of the infective focus. As the active process declines so also does the height of the blood-sugar curve. No fixed rule exists, however, since some apparently severe cases give a normal or only slightly disturbed sugar tolerance curve. Four cases of the severe type (Group 3) of this series fall into this category. On the other hand, accurate classification of the types of arthritis is oftentimes exceedingly difficult and can only be made after long observation. Hence it is not always possible to place every case in its proper group.

In Fig. 2 we have plotted out the average blood-sugar curves given in Groups 1, 2, 3, 4, and in the healthy normals during the glucose-tolerance tests. This chart gives a graphical representation of the facts stated above. Pemberton, in his publications on arthritis in soldiers of the American army, gives a graph (Fig. 3) showing the average blood-sugar curves in the glucose-tolerance test for the several severe moderate, mild, and convalescent arthritics, and normals.*

FIG. 2.



Average blood-sugar curves during glucose-tolerance tests.

The similarity between these two graphs is striking. The results, obtained in the glucose-tolerance tests in patients suffering from arthritis amongst the civil population, differ little from Pemberton's figures obtained from arthritics from the American army.

In a limited number of cases of the series the glucose tolerance response was ascertained after gross foci of infection had been removed, and we have tabulated the findings. (Table V.)

Corresponding to the fall in the glucose-tolerance curve in these four cases there was an improvement in their clinical condition. In Case 11, Case 28, and Case 37, there is a very marked reduction in the height of the glucose-tolerance curve after operative procedure for the removal of septic foci. This reduction does not always take place immediately after the infective focus has been removed, therefore a few weeks should elapse before a subsequent glucose-tolerance test is made. It is to be hoped that further opportunities will arise for the repetition of the glucose-tolerance tests after removal of foci of infection in cases of arthritis. Such a test, if consistent, should be extremely useful in ascertaining whether or not a given focus infection is the focus causative of the arthritic condition.

TABLE V.—*Showing Effect of Removal of Septic Foci on Glucose-Tolerance Curve.*

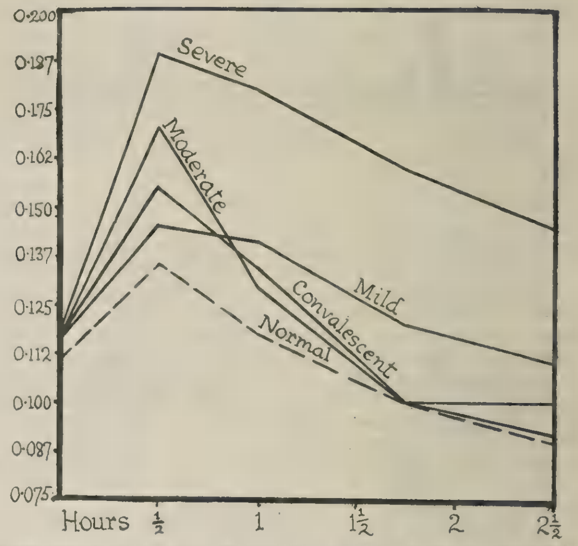
Blood Cultures.—Blood cultures were carried out for practically all the patients of the series. The medium used was ordinary bouillon containing 1 per cent. of glucose. Five to ten c.cm. of blood was taken from the most prominent vein around the elbow under aseptic precautions, and mixed with the glucose bouillon. It was then incubated at 37° C. for 48 to 72 hours. All the cultures remained sterile. This is in accordance with the fact that positive blood cultures are very rare in chronic arthritic cases. Pemberton, in his series, found few positive blood cultures.

FIG. 3.



Pemberton's graph, showing average blood-sugar curves in his glucose-tolerance tests.

Wassermann Reactions.—The W.R. of the blood sera of 53 cases of the series were ascertained and were found uniformly negative. Hence, there is no evidence in this series that specific disease plays any rôle in the causation of non-specific arthritis.

Conclusions.

1. In general the findings of Pemberton have been corroborated.

2. A lowered glucose tolerance is present in a large proportion of cases of arthritis and muscular fibrositis. This lowered tolerance is specially marked in the great majority of the severe infective cases as well as in the cases of periarticular fibrositis and muscular fibrositis.

3. The degree of intolerance is roughly proportional to the activity of the arthritic process.

---

* Pemberton : Archives of Internal Medicine, March, 1920.

4. The glucose toleration reaction tends to return to normal with convalescence and recovery. The return to normal, in most cases, is most rapid when the infective foci have been removed.

5. The estimation of glucose tolerance taken in conjunction with the other clinical signs and symptoms is of assistance in classification as well as in the prognosis of cases of arthritis.

6. In cases with a markedly lowered glucose tolerance, and in which the focus of infection cannot be found and removed, the prognosis is bad.

Our thanks are due to our colleagues on the staff of the Royal Bath Hospital for much help and encouragement throughout this investigation, and also to Messrs. N. Lissimore and S. Linfoot for their generous coöperation in the laboratory work.

OBSERVATIONS ON
ASTHMA IN CHILDHOOD.

BY A. DINGWALL FORDYCE, M.D.,
F.R.C.P. EDIN.,
PHYSICIAN TO THE ROYAL LIVERPOOL CHILDREN'S HOSPITAL.

THIS paper is based on the results of specific tests and on general clinical experience. It is proposed in it (1) to advert very briefly to the nature of asthma; (2) to consider tests in diagnosis; and (3) to discuss certain points in treatment.

Nature of Asthma.

The phenomena of an asthmatic attack result from the discharge of energy from the bronchial centre in the medulla, this discharge being stimulated by excitants of an anaphylactic, reflex, or psychical nature, or by combinations of these. These excitants are, however, only capable of causing this discharge when the centre is in a condition of hypertonus. It has always been recognised that inheritance was common in cases of asthma; it might be inheritance of an irritable bronchial centre, of a toxic idiopathy, or of both.

On the other hand, there is much evidence going to show that both irritability of the bronchial centre and a toxic idiopathy may be acquired.

The power of the psychical element in causation is well illustrated by Osler's report of the effect of smelling an artificial rose, Freeman's story of a mustard field, and Hurst's experience at Salisbury. As regards a reflex cause the nose, bronchial mucous membrane, stomach, and intestine are recognised as important foci of excitation, the difficulty being to prove whether such excitation acts in a purely reflex manner or is the origin of anaphylactic phenomena. What indications have we as to the nature of the asthmatic tendency—be it hereditary or be it acquired —in the light of modern views as to the anaphylactic character of the asthma phenomenon?

The tendency is certainly very closely connected with the activity of the central nervous system. Experimentally, general anæsthesia prevents the development of anaphylactic phenomena. Not only so, but when the exciting dose is given to an animal while under general anæsthesia, on recovering consciousness the animal is found to be vaccinated or desensitised. In a case of asthma we have to deal with contraction of bronchioles and secretion of bronchial mucus brought about by excitation of fibres of the vagus nerve. We have, then, particularly to deal with the autonomic or vegetative nervous system, and more especially with the parasympathetic. If the broncho-motor part of the nucleus of the vagus is unduly excitable, asthmatic symptoms may be produced by minimal stimuli. If the underlying condition is more general, it must involve in very special degree the autonomic nervous system. We have to deal with a general or a local sensitisation of the parasympathetic. We know that the two parts of the autonomic nervous system are antagonistic in function, a balance being kept by the normal function of the two—the sympathetic and the parasympathetic.

Various authors have associated asthma with vagotonia or excessive excitability of the vagus and parasympathetic. Others have found both vagotonia and sympatheticotonia or excessive excitability of both divisions of the autonomic nervous system. In either case such excitability of the autonomic nervous system must be closely associated with the functional activity of the endocrine glands. Stimulation of the sympathetic nervous system causes increased secretion of the thyroid, pituitary, and suprarenals, and probably diminished secretion of the pancreas, and vice versa. Directly opposite results occur from stimulation of the parasympathetic. The effect of fatigue in producing asthma is attributed to exhaustion of the suprarenals, diminution in their secretion, and, consequently, lack of check to the activity of the broncho-constrictor fibres of the vagus. Auld lays stress on the value of treatment by thyroid or pituitary, and Alexander and Paddock refer to the frequency of status lymphaticus in their cases of asthma.

There are thus obvious grounds for saying that asthma is closely associated with the functional activity of the autonomic nervous system and with the endocrine glands. But, having said so much, we necessarily imply that there is present a peculiarity in general metabolism, and every factor bearing on metabolism must play a part more or less important in encouraging the development of, or checking the tendency to, the asthmatic condition.

Symptoms.—The symptoms of asthma commonly develop during the first few years of life. Coke and Rolleston—as others—bring sharply to the fore considerations regarding bronchitis and food. It is usually difficult and not infrequently impossible to date exactly the onset of asthma in early childhood because of its intimate association with bronchial catarrh. Bronchial catarrh is at first usually the outstanding feature in the asthmatic attack, but this fact is no reason for excluding the possibility that bronchial catarrh, particularly if frequently repeated, may in some cases, instead of being a symptom of asthma, be actually the exciting cause. In early childhood the whole central nervous system is unstable; spasm of the bronchi can readily be produced by irritation from within; repeated irritation and repeated spasm in a child whose nervous system is peculiarly unstable will eventually lead to development of symptoms with ever milder and milder stimulation. On the other hand, we have to remember that rickets and recurrent bronchitis are common conditions, asthma in comparison with them—rare.

Importance of Bronchial Catarrh.—This is, further, the period of life when measles and whooping-cough are common, both of which include bronchial catarrh among their symptoms, and to both of which the onset of asthma is sometimes attributed. Rolleston[1] states that:—

> "After infections . . . hypersensitiveness to some protein becomes manifest; this may be ascribed to some residual bacterial infection and to the absorption of the foreign protein thus provided. It is also possible that the infection so alters metabolism in the liver and elsewhere that protein bodies of so abnormal a character as to be 'foreign' are produced."

It is also possible that the prolonged intrabronchial catarrh may be itself a reflex irritant. The further point here emerges as to the nature of the infecting organisms in bronchitis, and more particularly in bronchitis persisting after measles or whooping-cough.

Tuberculous infection of the bronchial glands is comparatively common in young children, and in the great majority of cases is not associated with symptoms of an asthmatic nature. It is, however, always wise to remember the warning of Eustace Smith that many cases of asthma in early life are due to direct pressure by swollen glands upon the air-tubes; tuberculous children are frequent sufferers from pulmonary catarrh: in these attacks the glands undergo a rapid temporary increase in size, and their enlargement may set up serious pressure upon the windpipe at its bifurcation.

---

[1] Brit. Med. Jour., 1921, ii., 231.

Foods.—As regards foods, it is stated that absorption of the protein of some particular food, and especially milk in the first year, is the main cause of asthma. Recent advances of knowledge along this line have been largely in relation to and dependent on cutaneous reactions to various proteins, and will be more fully considered when dealing with such reactions. It is, however, advisable to note here certain points. H. W. Barber, speaking of protein sensitisation, says [2]:

> "It is probable that acquired sensitisation to food and bacterial proteins depends frequently on the state of the alimentary canal, and that incomplete digestion or a catarrhal condition of the intestinal mucous membrane, may result in the absorption of proteins direct into the blood-stream, thereby rendering them capable of acting as antigens."

Histamine, formed in the intestine as the result of putrefaction, is recognised as a probable cause of one class of asthma, and Schloss has shown that although the intestinal mucous membrane of normal infants is impermeable to undigested foreign protein, this protection is impaired in abnormal conditions of the alimentary canal. Alimentary disturbance of one sort or another is of very common occurrence among children of all ages and of every class, and metabolism generally is markedly unstable.

Nervous Influences.—It is hard to draw the boundary line between errors or failures of digestion in children and nervous influences, and there is much reason for ascribing to nervous influences many cases of both glycosuria and acetonuria. Digestive upset and nervous instability frequently lead to spasm in early childhood. Rickets certainly is the chief cause of spasm, and rickets is more common among children of the poorer class than among those of the well-to-do, whereas the reverse is true of asthma. But the children of the well-to-do are usually more nervous and highly strung; they suffer much from digestive disorders and they are prone to broncho-pharyngeal affections. They live in various respects a less natural nervous life than their poorer brothers and sisters. They are often stimulated to observation, thought, attention in a manner altogether too forced, while at the same time allowed to give way to caprice and whim.

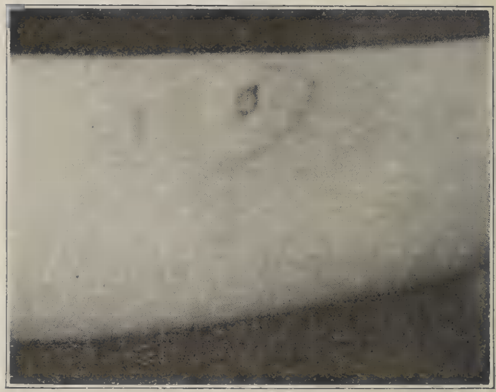
Tests in Diagnosis.

(*a*) *Protein Cutaneous Tests.*—My experience of these tests consists in the examination of 50 patients —40 child asthmatics and 10 children suffering from such conditions as epilepsy, œdema, and indigestion. Twenty-eight of the 40 cases of asthma were what may be called straightforward, uncomplicated asthmatics. Of these, nine were positive to pollens, one to dog, one to cat, and one to bacon. One was negative to mother's milk but was cured on weaning. Of the other 15 cases, averaging 17 tests each, all were negative. Several of the cases positive to pollen were tested several times and at different times of the year and found positive again. In one of these cases the information was volunteered by the parent that the boy "can bring on an attack of asthma when he likes"; in another, "We can't take him to church because he always takes an attack if he is dressed for it." The dog-asthmatic was a boy of 16 who had suffered from asthma for years, and been treated by all ordinary remedies, including vaccines. There was no indication as to cause except that since he had been going to school the attacks only occurred on returning home to Liverpool. Cutaneous tests with many foods, bacteria, cattle-hair, and goose feather were negative. To dog-hair the reaction was strongly positive. On inquiry it was found that three dogs were kept at home and that he never had asthma when away from dogs. Abstinence from dog company worked a cure. The cat-asthmatic was a girl of 18 who suffered from epilepsy. She was negative to a variety of protein tests, but positive to diphtheria antitoxin and violently positive to cat-hair. As a little child she had suffered from asthma; it was noticed that playing with the cat induced an attack; the cat was thenceforth banished and the asthma ceased. Later she developed epilepsy, and the problem put to the doctor was, "How about bringing back a cat?" The case positive to bacon was that of a boy aged 10 years who had suffered from recurrent attacks of asthma and œdema from the age of 9 months. He was negative to various protein tests, but strongly positive to bacon and mildly positive to beef. It was found that he ate a great deal of bacon, and this was cut out of his diet. Two months later he was greatly improved, but still gave a strong positive cutaneous reaction with bacon. Of the 12 complicated cases of asthma, one was a case of sneezing and œdema in a baby; the cutaneous reaction with mother's milk was positive, and the child was cured by weaning. The other 11 were cases in which the asthmatic symptom was obviously secondary to some other condition—e.g., gross indigestion, lithæmia, tuberculous adenitis, &c.—and in all these cases tests were negative.

What do we mean by the terms positive and negative, and what does the reaction signify? It has been stated that "of asthmatic children some 90 per cent. give positive reactions" (Coke)[3] and that multiple positive reactions are most common in those cases in which the asthma commenced in early childhood. Shannon[4] reports up to 16 positive reactions in various babies aged a few weeks or a few months. But this author says:—

> "The interpretation of the positive reaction has been based on the occurrence of an erythema at the site of the test, as well as a wheal."

I doubt if we are justified in considering an erythematous reaction alone to be confirmatory evidence of specific anaphylactic reaction. Both asthmatic and non-asthmatic children vary considerably in the degree of erythematous reaction to cutaneous tests. Improvement in cases of multiple so-called "specific" sensitisation follows on treatment founded on these so-called specific positive reactions, but such treatment necessarily implies drastic supervision and curtailment of diet, &c., and the result of treatment is no proof that the reactions were signs of primary specific sensitisation. By positive reaction I mean the existence of a well-marked wheal. (See illustration.)



Positive cutaneous reaction on forearm, with "control" above.

As original controls for my cutaneous tests I took six children between the ages of 9 years and 12 years —two in good health, two in fair health but with large tonsils, and two in fair health but with pronounced thyroid hyperplasia. Each child was tested with 32 cutaneous tests, was thereafter given 1 gr. of thyroid daily for seven days, and was then again tested with the same 32 cutaneous tests.

---

[2] Ibid., 1921. ii., 554.

[3] Brit. Med. Jour., 1921, i., 372.

Amer. J. of Dis. of Child., May, 1922.

In no instance was a wheal reaction obtained, but the degree of erythema excited varied widely. Sidlick and Knowles,[5] writing on the Value of Cutaneous Sensitisation Tests Employed in Eczema and Papular Urticaria of Childhood, conclude as follows :—

> "The elimination of specific offending proteins will not affect a cure in all cases of eczema or urticaria in children. To be of value the food test must be + + or greater. We may assume that by correcting the gastro-intestinal abnormalities an increase in the number of clinical cures is certain of attainment."

According to Herman[6] :—

> "It must be remembered, however, that a skin reaction in order to be positive, must have the typical formation of pseudopod-like processes extending out from the wheal. A wheal in which there are no such processes must be considered negative even in the presence of a definitely negative control."

R. Cranston Low[7] says :—

> "Cases of eczema, &c., especially in children, often give positive reactions to more than one food, and yet when the food or foods are removed from the diet no improvement occurs in the skin, and also when the patient is given these foods the eruption is not made any worse. The difficulty is to know which food, if any, is to blame, and one may get reactions to several foods and the one which is to blame be omitted, as it is impossible to test a case to all possible foods."

I have found, in a child tested *during* an attack of asthma, unusually marked erythematous reactions to *all* proteins used, but these reactions do not appear to me to be specific.

(*b*) *Bacillary Tests and X Ray Photographs.*—If we accept the probability of asthma being an anaphylactic phenomenon, we are at once faced with the possibility of the cause being bacterial in nature. We want to know, then, in the first place if there are any unusual forms or unusual numbers of bacteria present in the mouth, naso-pharynx, intestines, urine, or sputum, if obtainable. Hurst quotes Dr. John Eyre as saying "that the organism which most frequently has a specific relation with asthma is a bacillus of the Friedländer group"; Sir Leonard Rogers and others report successful results from treatment by autogenous streptococcal vaccines; Danysz pins his faith to intestinal micro-organisms—and so on. Except by autogenous vaccination or removal of specific micro-organisms it is impossible to tell the causal connexion between bacteria and asthma. Cutaneous tests are generally negative, but even so it is possible that the particular bacteria may yet be the primary cause in that they produce conditions which render possible the development of anaphylactic symptoms by other agencies.

It is always advisable to have an X ray photograph of the lungs. "Normal" chests are rare.

Treatment.

I wish to emphasise the importance of the non-specific side of treatment. Asthma in a young child is a serious condition for the patient both as regards his health and his education. It is also a trying and painful condition for his parents and friends to observe. But repetition may dull anxiety, and, failing a ready remedy, resignation to fate may supervene. Or the awe-inspiring aspect and recognition of heredity may dull or entirely overwhelm continuous effort.

The child has attached to him the label "asthma." Wanted—the antidote or cure; expected—an equally specific remedy as the disease is specific. But asthma is a condition with wide variations, and one in which many ætiological factors may be operative. In some cases the specific excitant can be determined, and for this purpose cutaneous protein tests are of notable value. In other cases the search for a specific origin is unsuccessful. In the former class of case specific therapy is indicated, in the latter it is not possible. But in both general careful supervision of methods of living is essential—a supervision which must be long-continued and may prove irksome, which may be more or less successful and will have to be modified from time to time as experience indicates—and which can be expected to meet with no dramatic success. I do not propose, then, to consider now treatment by specific desensitisation, autogenous vaccination, auto-serum therapy, peptone, chloral, organotherapy, or drugs. I merely note the importance of removal of irritant and septic foci. I wish, however, to speak more fully on the subjects of diet, climate, and discipline.

Diet.—It is necessary to recognise that loose speech and thought are wholly wrong when dealing with the diet of the individual child. If we recognise—as we must—that through diet we can influence most powerfully organic function generally, we must, at least, know approximately of what that diet consists. In how many households does any single member know accurately what a child inmate, over the age of 3 years and not in bed or on a written-out diet, eats and drinks in the course of a day? In how many instances are the details given by mother or nurse to the doctor largely inaccurate? The peculiarities of child-life and the complexities of child supervision clearly indicate the need of accuracy in dietetic plan. This, in turn, demands written instructions.

I do not wish to exaggerate the importance of diet or of indigestion in cases of asthma. After all, our knowledge as to what constitutes a satisfactory diet, and in what perfect digestion consists, is not very accurate. But we surely commit a cardinal error in the case of a child-asthmatic if we do not take the details of diet into our own hands and attempt by clear orders to establish a satisfactory dietetic regime, to remove digestive troubles, and consequently to form a basis for further procedure.

It is not uncommon to be told that between attacks the child is quite well. It is much more common to find oral sepsis, indigestion, a mal-regulated diet, and constipation present. One is told, for example, that "the appetite is capricious" or "he has no appetite" or he will eat any quantity of meat, or in another case of potatoes, or yet in another of raw fruit, and he won't touch this or that or the other thing. Or he has thread-worms or a tic, or is easily tired and develops dark rings under his eyes. In all such cases digestion is faulty and demands remedy. We have been told by different authors at different times that the diet in asthma should be of a lowered protein content, by others of a low fat content, and still others of a low carbohydrate. The first essential in every case is, however, to remember the old axiom to treat the patient and not the disease. Get within the patient's powers of digestion. Avoid a lop-sided diet. Remember that fatty food is important and usually well taken by children, but that if the power of satisfactory digestion of fat is once seriously impaired it is hard to recover, and at best can only be done slowly and not forced. Remember, again, that a common dietetic error in childhood is excessive carbohydrate food, that masses of "saps" or potatoes or sweets are highly inadvisable, and that raw fruit, if allowed at all, must be taken as directed. Remember, lastly, that a child asthmatic is a child who has given evidence of a peculiarly unstable nervous system, even if it be only in part, and that while the first consideration in drawing up dietetic regulations must be the fundamental needs of the age of the child in the light of its particular powers of digestion, yet that the protein content of the food, and particularly the animal protein, should be kept low at least until definite improvement has occurred. Rest—physical and mental as well as digestive—is the greatest digestive tonic we possess. A short period in bed is frequently the most satisfactory method of recovering good digestion.

If a case of asthma have attacks due to a specific food protein—whether discovered by the cutaneous test or not—and if in addition there be marked indigestion, nothing but general good can result from improvement in digestion, and it is even possible that the improved conditions may so alter absorption as to affect favourably the specific poison. On the other hand, should attention be entirely focussed on the specific poison to the extent of adopting only specific treatment, then, while it is true that the symptoms may disappear, it cannot but be apprehended that, basal conditions remaining unaltered, a recurrence of attacks may occur originated by a new specific poison.

Climate.—I shall not linger on this subject, extremely important though it be. In a young child repetition quickly develops into habit. It is therefore in a case of asthma very important to prevent recurrences or lengthen intervals of attacks; the earlier the age the more important is this; and change of climate may produce this result when no other discoverable means will.

Discipline.—A healthy little child is a being whose central nervous system, including his autonomic nervous system, is naturally unstable. Slight causes produce widespread results, new experiences create deep impressions. Health implies individuality, and this, combined with inexperience, leads to a desire for daring, adventure, or, at least, a desire to do the forbidden or the unusual. The natural negativism of children is due to healthy individualism in a being of unstable nervous poise. Recognition of this mental trait is common knowledge in almost all nurseries; it is, however, often misunderstood and not rarely abused. Its existence demands for proper use a suitable mental environment of suggestion and recognition of a further childish trait—namely, that of the ego being the supreme centre. Everything circles round self—self must impose itself on its environment. The important events in nurseries are feeding, defæcation, and urination. If their importance be rated too highly it is easy for the child to become conspicuous. If he be put on the chamber and mother and nurse hover around in hushed suspense while he does his deeds, consult solemnly over results, and develop prolonged fuss over him if expected results are not forthcoming, he quickly sees a glorious opportunity of satisfying his egoistic vanity and his taste for negativism. He simply sits and does not perform. At meals, likewise, unless treated with suitable unconcern and a modicum of firmness, likes and dislikes to foods are readily initiated, and by repetition become really nervous habits. The power of suggestion is great, the nervous mechanism malleable and impressionable, and habit is soon acquired.

How is it with the child whose nervous system is in part at least hyperexcitable—a child who suffers from asthma, which may be psychical, anaphylactic, or reflex in nature? He must surely require still greater care in training, and no treatment can be satisfactory which leaves such training out of account. The nervous psychical element in the causation of an attack is very marked in childhood. In some cases the condition appears to be primarily a true hay asthma, in others it may be food or animal anaphylaxis, in others perhaps reflex. But in very many, if not all, there seems to be little ground for doubt that many of the succeeding attacks are really of the nature of habit and that stimuli of almost any form may act as excitants. His condition demands treatment of peculiar nervous instability by nervous influence. Restfulness and calm are important, freedom from mental strain is necessary, and understanding suggestion from his attendants is of the greatest value. Egoism and negativism are marked characteristics of healthy children; they are more rather than less marked in ailing children. Attendants must recognise their existence, and deal with them either by avoiding their being aroused in matters of importance, or by so dealing with the subject as to ensure that the expected childish reaction will be in the direction desired.

INDICATIONS AND RESULTS OF MYOMECTOMY FOR UTERINE FIBROIDS.*

By ARTHUR E. GILES, M.D., B.Sc. Lond.,
SURGEON TO THE CHELSEA HOSPITAL FOR WOMEN.

In recent discussions on the treatment of uterine fibroids, the alternatives of hysterectomy on the one hand and X ray and radium treatment on the other have generally been dealt with as though they exhausted the possibilities of treatment. Myomectomy has been almost entirely overlooked. At the meeting of this section in April last a paper was read by Dr. Fletcher Shaw on the X ray treatment of fibroids, as a sequel to a former paper by Drs. T. Watts Eden and F. Lionel Provis. I then felt that the case for myomectomy might well be presented, and this contribution is the result. I hold the view that in the majority of cases of fibroids requiring surgical treatment, hysterectomy is the more suitable and also the more satisfactory operation, and that the scope of myomectomy is restricted to the minority of cases. Hysterectomy requires no justification; it is generally accepted as a sound procedure, surgically and clinically. But myomectomy needs to be justified by its results, and reasons must be stated as to why it should be preferred; its limitations must also be acknowledged and the conditions of its suitability defined.

The outstanding claims for myomectomy are, first, that the uterus is preserved for the important function of child-bearing, and secondly, that the patient is thereby spared the mental distress of feeling that an essential part of her womanhood has gone. The broad-minded advocate of myomectomy will, I think, at once concede that in a woman who is past the child-bearing age the first claim disappears, and the second has only an academic existence—although, as I shall point out, there may be reasons for preserving the uterus that are not founded on its child-bearing function. But we may properly narrow the issue to the consideration of myomectomy versus hysterectomy in the child-bearing period.

The advocate of myomectomy is, then, I think, called upon to show, in the first place, that the preserved uterus is in fact, as well as in theory, capable of child-bearing; and in the second place, that there is a reasonable prospect of a cure, both anatomically and symptomatically; in other words, that in a large majority of cases there will be no return of fibroids, and that the patient will menstruate normally. The case for myomectomy will be best presented if we begin by examining the question whether it is justified by its results; and if the answer proves to be in the affirmative, we can then consider its scope and limitations. A separate short section will be devoted to the interesting subject of myomectomy during pregnancy.

Results of Myomectomy.

We may glance first at the immediate results—namely, the mortality—as compared with hysterectomy; for this purpose my own statistics will serve as well as any. The figures (to the end of December, 1922) are as follows:—Hysterectomy for fibroids: 1004 cases, 17 deaths, mortality 1·69 per cent. Myomectomy: 173 cases, 3 deaths, mortality 1·7 per cent. These figures represent all cases from 1897. The present-day mortality is lower, and the figures from the end of 1910 to date are as follows:—Hysterectomy: 701 cases, 5 deaths, mortality 0·71 per cent. Myomectomy: 113 cases, 1 death, mortality 0·89 per cent. There is thus very little difference in the mortality of the two operations; certainly not enough to make this a deciding factor in the choice of operation.

Later Results.

In my work on the after-results of abdominal operations published in 1910, I was able to give particulars of 40 cases traced out of 51 operated upon. Of the later 116 cases, I have particulars of 53. I did not attempt to trace the histories of patients who were over 45 years of age at the time of operation. I will take in order the three questions investigated in the previous cases.

---

* A paper read at a meeting of the Section of Obstetrics and Gynæcology, Royal Society of Medicine.

1. *What is the Likelihood of a Recurrence of Fibroids?*—In the first series, of 39 cases examined, the uterus was found of normal size, with no return of fibroids, in 35 cases, or 90 per cent. In the present series, of 49 cases examined, or reported upon by their doctors, the uterus was normal in size without fibroids in 41 cases; it was enlarged, without fibroids, in 3 cases; in all, 44 cases without fibroids, or 90 per cent., as in the first series. In 5 cases fibroids were observed, the notes about them being: (1) Fibroid in fundus: hysterectomy advised on account of bleeding; (2) fibroid size of pea on posterior wall; (3) multiple fibroids, hysterectomy done nine years after myomectomy; (4) fibroid size of mulberry on anterior wall; (5) fibroid size of pea on anterior wall. The conclusion is that the liability to return of fibroids may be represented as 10 per cent.

2. *How is the Menstrual Loss Affected?*—In the first series the menopause had occurred before the operation in three cases, and in one case there was no further loss after operation. Of the remaining 36 cases, menstruation was normal or moderate in 31, or 84·5 per cent., and free or profuse in 5, or 15·5 per cent. In the present series we can exclude 6 cases where the menopause preceded or synchronised with the operation. Of the remaining 47 cases, menstruation was normal and moderate in 36, or 75·1 per cent.; and in 11 cases it was profuse, either at first, or later on; or there was intermenstrual loss. Taking all the cases together, we find that of 83 cases menstruation was normal in 67, or 80·7 per cent. The conclusion is that there is liability to menorrhagia or metrorrhagia after myomectomy in about 20 per cent. of cases. This result is not altogether surprising; because it is clear that unless we open the uterine cavity every time we do a myomectomy some small intra-uterine growth may easily be overlooked.

In order to show that sufficient time had elapsed to judge of results, I may mention that the time between the operation and the report on the cases in the present series was as follows:—

Years.	Cases.	Years.	Cases.	Years.	Cases.
1 to 2	4	5 to 6	1	9 to 10	7
2 ,, 3	8	6 ,, 7	12	10 ,, 11	3
3 ,, 4	2	7 ,, 8	2	13	1
4 ,, 5	5	8 ,, 9	6		

3. *Is the Uterus Serviceable for Child-bearing after Myomectomy?*—In the first series there were 15 married women under 45 years of age: of these, one was four months pregnant at the time of operation, went to term, and became pregnant again; two others became pregnant after the operation. In the present series I have after-histories of 38 married women under 45, including three who were single at the time and married afterwards. I have drawn up a table of these cases. (Table I.)

One, who was pregnant at the time of operation, died of eclampsia at her confinement; and two did not live again with their husbands after operation. Of the remaining 35, 11 became pregnant after the operation, including two patients who were pregnant at the time, went to term, and became pregnant again. One patient had two children, and another had four. In all, therefore, of 50 women who had the chance of conceiving after operation, 14 became pregnant, or 28 per cent.

Now the question that we have to decide is this: Are the results of myomectomy good enough to justify us in practising this operation in suitable cases? My answer is an unqualified "Yes," on the ground that the advantages far outweigh the disadvantages. The advantages are represented by the occurrence of pregnancy in 28 per cent. of the women who had a chance of pregnancy, and by the satisfaction which patients derived from the consciousness that they remained after the operation "like other women." This satisfaction cannot be expressed in statistics, but it is nevertheless a very concrete advantage. The disadvantages are the possibility of the return of fibroids, which is a 10 per cent. chance; and the possibility of further menstrual trouble, which is a 20 per cent. chance. Some women doubtless would prefer the assurance, which hysterectomy gives, that there will be no return of their troubles, and that the operation is therefore final. But I am persuaded that the great majority of women of child-bearing age would prefer to take the risk which the figures indicate, for the possible chance of having a baby. The risk of a second operation being necessary is not as great as 10 per cent.; hysterectomy has been required in only five cases out of the total 167—that is, in just 3 per cent.

TABLE I.—*Results of Myomectomy in Relation to Pregnancy.*

No. in present series.	Age.	Date of operation.	Pregnancies after operation.
2	38	Nov. 11, 1909.	None. Husband in asylum all the time.
10	18*	June 12, 1911.	Married since. Conf. Oct., 1921.
13	30	March 14, 1912.	None.
14	39	April 15, 1912.	P. op., went to term. None since.
19	33	June 30, 1912.	None.
23	30	Jan. 14, 1913.	None.
25	32	Jan. 30, 1913.	None.

32	41	Sept. 25, 1913.	None.
33	31	Oct. 6, 1913.	Conf. Jan., 1915, April, 1917, March, 1919, Aug., 1922. Prior to operation had been married six years without children.
34	37	Nov. 29, 1913.	None.
39	38	April 24, 1914.	None. Died in May, 1918.
44	34	June 8, 1914.	Conf. Oct., 1917. None since.
45	34	July 9, 1914.	None.
46	29	Oct. 14, 1914.	P. op., went to 7½ months. None since.
47	42	Oct. 22, 1914.	None.
49	30	Nov. 6, 1914.	Conf. since, date unknown.
51	35	Dec. 2, 1914.	Conf. June, 1916.
58	34	Oct. 7, 1915.	P. op., went to term. Another conf. May, 1920.
59	35	Oct. 11, 1915.	P. op., went to term. Another conf. Jan., 1919.
61	35	Nov. 11, 1915.	None.
62	32	Jan. 3, 1916.	None.
63	37	April 17, 1916.	P. op., went to term. None since.
64	34	May 1, 1916.	None. Has not lived with husband since operation.
69	37	Oct. 9, 1916.	P. op., went to term. Patient died of eclampsia.
71	30	Jan. 11, 1917.	None. Premature menopause April, 1921.
72	35	Jan. 22, 1917.	Conf. Feb., 1918.
81	35	Nov. 26, 1917.	None.
82	33	Feb. 6, 1918.	None.
88	40	Dec. 30, 1918.	P. op., went to term. None since.
92	36	Nov. 25, 1919.	P. op., went to term. None since.
97	36	Feb. 5, 1920.	P. op., went to term. None since.
98	31	March 18, 1920.	None.
100	31	April 14, 1920.	None.
103	28*	June 28, 1920.	Unmarried at time of operation. Married June, 1922. Now 2½ months pregnant.
105	29	July 20, 1920.	Conf. Feb., 1922.
106	38	July 21, 1920.	None.

* Single. P. op. = Pregnancy at operation. Conf. = Confinement.

I therefore submit that, judged by the criterion of results, the advantages of myomectomy definitely outweigh its disadvantages in the surgical treatment of uterine fibroids, in a restricted class of cases. My own sense of this restriction is sufficiently expressed in the fact that of 1177 cases of uterine fibroids treated surgically, hysterectomy was done in 1004, or 85·3 per cent. The proportion of myomectomy to hysterectomy was thus 1 to 6.

We may now examine the scope and limitations of myomectomy.

Indications for Myomectomy.

There is one important indication for myomectomy, and there are several subsidiary ones. I will take the important one first.

1. *The fact that the patient is of child-bearing age.*—The younger the patient the greater should be the effort to save the uterus, and I should say that, broadly speaking, myomectomy is the operation of choice in women up to the age of 40. In single women the indication is not so great as it is in married women, especially after the age of 30; because after this age the expectation of child-bearing is necessarily less in the spinster from the fact that she has first to get married. The generalisation of age in the case of married women may well be qualified by the question of previous pregnancies; when a woman has half a dozen living and healthy children we need not be so concerned to save the uterus as we should be in the case of a woman who has had no child and is ardently desirous of having one. This reflection is well illustrated in a case of myomectomy during pregnancy, to which I shall refer later. The influence of age and of the married state upon my own practice is set forth in Table II., which shows the proportion of myomectomies to hysterectomies at different ages in single women, in married women, and in the two groups taken together. In five-yearly periods the percentage of myomectomies, which stands at 56·6 for all cases under 30 in married women, progressively falls to 40·1, 26·7, 6·1, and 5·5 and rises a little to 10·0 in the case of women over 50. In single women the percentage is 45·0 for all cases under 30, and falls to 21·3, 8·3, 8·6, and 4·0, and rises to 10·0 in those over 50. Taking all the cases together, the percentage is 52·0 in women under 30, and in successive five-yearly periods it is 34·3, 19·2, 6·9, and 5·1; and for women over 50, 10·0. It will be noticed that the proportion of myomectomy is markedly higher in married women than in spinsters up to the age of 40, after which there is not much difference.

TABLE II.—*The Proportion of Myomectomies to Hysterectomies at Different Ages.*

Age.	30 and under.		31–35		36–40		41–45		46–50		Over 50		Total.	
	No.	%	No.	%	No.	%	No.	%	No.	%	No.	%	No.	%
Married women—														
Myomectomy	17	56·6	37	40·1	36	26·7	13	6·1	11	5·5	11	10·0	125	16·0
Hysterectomy	13	43·4	53	59·9	103	73·3	201	93·9	190	94·5	99	90·0	659	84·0
Total	30		90		139		214		201		110		784	
Single women—														
Myomectomy	9	45·0	10	21·3	7	8·3	8	8·6	3	4·0	4	10·0	41	11·4
Hysterectomy	11	55·0	37	78·7	78	91·7	85	91·4	72	96·0	36	90·0	319	88·6

Total	50		137		224		307		276		150		1144	

2. *Association of uterine fibroids with prolapse and procidentia.*—The rise in percentage of myomectomies after the age of 50 is explained by the fact that a number of these patients had prolapse or procidentia. In the presence of this complication I consider that it is very important to preserve the uterus; because this can be fixed up to the abdominal wall when myomectomy has been done, and thus play an essential part in the cure of the displacement. When the uterus is removed in conditions of procidentia there is a marked tendency to prolapse of the vaginal walls, which is apt to be very troublesome, and to defy, in severe cases, even extensive plastic operations on the vaginal walls and perineum.

3. *A deep-rooted objection on the patient's part to hysterectomy.*—In my experience the great majority of women suffer no more than a passing regret for the loss of the uterus, especially when it is explained to them that the presence of the tumours has rendered it incapable of serving its one function, that of child-bearing; that the uterus is not the essential organ of sex, and that its removal has no effect on the specially feminine characteristics and does not render a woman any less able to live a married life. But there are a few women swayed more by sentiment than by reason, to whom the loss of the womb seems a greater calamity than the loss of life itself; to them this organ appears to be the focus and essence of their personality as women, and if hysterectomy be done, it is apt to be followed by a profound and lasting depression which approaches the border-line of mental instability. In dealing with a patient of this kind, it is clear that a special effort should be made to save the uterus, even if the age of child-bearing be past, and myomectomy entails a rather higher operative risk and the possibility of a return of fibroids. But in such circumstances the surgeon may feel disposed to advise the adoption of X ray treatment, rather than to undertake what seems to him to be an undesirable surgical procedure.

4. *Certain Characters of the Tumours.*—When a tumour is solitary and pedunculated, and not associated with excessive bleeding, a myomectomy may properly be done, whatever may be the age of the patient and the chances of pregnancy. Even an interstitial tumour unassociated with hæmorrhage may be enucleated. In fact, when none of the previously considered factors have to be considered, the deciding question will probably be "What is the simplest and safest operation?"

The Limitations of Myomectomy.

I have so far considered conditions in which myomectomy should be done unless there is some strong reason to the contrary. I have now to enumerate those in which myomectomy should not be done unless there is some preponderating reason for it.

1. *Age Factor.*—After the age of 40 to 45, I consider that hysterectomy should be the rule, especially when there are multiple fibroids and when there has been excessive hæmorrhage.

2. *Condition of Uterine Appendages.*—When fibroids are associated with double tubal disease or with bilateral ovarian tumours, hysterectomy is the proper procedure.

3. *Size and Position of Tumours.*—Whatever the position or number of the tumours, if myomectomy is going to leave a battered and useless organ, hysterectomy should be done. Cervix fibroids almost invariably call for hysterectomy, though I have occasionally done a myomectomy even in these cases. A fibroid in the broad ligament may, if enucleated, leave the uterine vessels in a highly vulnerable condition; my first myomectomy was of this kind, and I had to reopen on account of hæmorrhage. The mere number of the tumours does not greatly matter, as long as a good and serviceable uterus is left.

4. *Excessive Hæmorrhage.*—When a patient has had great losses and is seriously drained thereby, hysterectomy should be the rule. If urgent reasons call for an attempt at myomectomy, the uterine cavity must be opened, and any submucous or intrauterine growth must be removed. Otherwise hæmorrhage will continue, and the operation will have been done in vain.

5. *Temperament of the Patient.*—Just as there are a few women whose temperament renders it important to save the uterus, so there are others whose tempera-

ment will turn the scale in favour of hysterectomy. They are the patients to whom an operation is such an ordeal that whilst they will face it bravely if they have the assurance that it is going to mean a definite cure, they could not tolerate the prospect that the ultimate result of the operation might be doubtful. With them even considerations of possible future pregnancy and of preservation of feminineity have no weight compared with the all-important need for being completely and finally cured. With such a patient, if there is any doubt at all as to the issue of a myomectomy, hysterectomy should be done.

Myomectomy during Pregnancy.

Fibroids associated with pregnancy do not necessarily call for surgical treatment. When they are causing no symptoms, and do not seem likely to interfere with labour, it is best to leave them alone, always provided that the patient can be kept under observation so that operation can be undertaken if urgent symptoms arise, and that the medical attendant is on the look out for trouble during labour. After the confinement the fibroids can be dealt with on their merits. Surgical treatment may take the form either of myomectomy during pregnancy or of Cæsarean section combined with myomectomy or hysterectomy at term. In exceptional cases hysterectomy in the early months of pregnancy may be required, but it should only be done if symptoms are urgent and there are cogent reasons against the adoption of conservative procedures.

Myomectomy during pregnancy is indicated in three groups of conditions: First, when the tumour or tumours appear to be increasing rapidly in size; secondly, when the patient is suffering from pain, pressure symptoms, or indications of septic or degenerative changes in the tumours; thirdly, when the position of the fibroids makes it probable that labour will be obstructed, in which case myomectomy is done for the purpose of avoiding the necessity for Cæsarean section and of allowing the confinement to take place naturally. In the second group severe and persistent pain is, of course, a sufficient indication in itself. The effects of pressure may be exerted in relation to the bowel, the bladder, the diaphragm, the iliac vessels, or the nerves of the sacral plexus; and any one of these may call for interference. With regard to degenerative changes, it is well known that when fibroids are associated with pregnancy they are specially liable to undergo that form of necrobiosis known as "red degeneration"; and that the onset of this process is frequently marked by pain so acute and severe as to simulate the torsion of the pedicle of an ovarian tumour. In one of my cases operation was undertaken under the impression that the patient had an ovarian cyst with a twisted pedicle. In the other cases myomectomy was the intended operation. In all, I have had 13 cases of myomectomy during pregnancy, and I have thought them of sufficient interest to make a tabular statement of them (Table III.)

The period of gestation ranged from a few days to six months. In the case of "a few days," the fact of pregnancy was not known at the time; the tumour was a large subperitoneal one, and the first intimation I had of the pregnancy was two months after the operation, when the patient presented the signs and symptoms of a two months' pregnancy and stated that coitus had taken place two or three days before the operation and not since. In Case 11 the patient, aged 36, had been married ten years, and this was her first pregnancy. The uterus was a mass of fibroids, and in other circumstances I should have had no hesitation in doing hysterectomy. But a child had long been desired, and this was obviously the patient's only chance. I removed ten fibroids, several being the size of a fist, and one partly necrotic. Some were pedunculated, but several had to be enucleated from the substance of the uterine wall. She had a normal confinement at term. The results of the last two I have been unable to trace; in the remaining 11 pregnancy was not interfered with, and all went to full time, except one whose labour came on at seven and a half months, but the child was alive and survived. In Case 8 the mother developed eclampsia and died, and the child was still-born. Two other children died a few days after birth from injuries during labour, one being in a case of contracted pelvis. Both mothers had the satisfaction of a living child subsequently; the one with the contracted pelvis being delivered by Cæsarean section.

TABLE III.—*Results of Myomectomy During Pregnancy.*

No.	Age.	Date of operation.	Period of gestation.	Result.
1	35	Jan. 11, 1909.	4 m.	N. conf. June 8, 1909. M. & c. alive.
2	39	Apr. 15, 1912.	4½ m.	N. conf. Aug. 25, 1912. M. & c. alive. A first pregnancy.
3	34	Mar. 17, 1913.	3½ m.	N. conf. Sept. 8, 1913. M. & c. alive.
4	29	Oct. 14, 1914.	4½ m.	Conf. at 7½ m. Jan., 1915. M. & c. alive.
5	34	Oct. 7, 1915.	3 w.	Conf. June 21, 1916. Baby injured at birth, died three days later. Conf. of healthy child May, 1920.
6	35	Oct. 11, 1915.	2 m.	Conf. May 10, 1916; contracted pelvis; four days' labour. Child died soon after. Pregnant again; successful Cæsarean section Jan. 16, 1919.
7	37	Apr. 17, 1916.	6 m.	N. conf. Aug. 27, 1916. M. & c. alive.
8	37	Oct. 9, 1916.	3 m.	Conf. at full time. Mother has eclampsia and died. Child still-born.
9	40	Dec. 30, 1918.	3 m.	Conf. June 29, 1919. Instrumental delivery. M. & c. alive.
10	36	Nov. 25, 1919.	A few days.	N. conf. Aug. 12, 1920. M. & c. alive.
11	36	Feb. 5, 1920.	4 m.	N. conf. July 5, 1920. M. & c. alive.
12	38	Mar. 4, 1920.	3 m.	Unknown.
13	43	Apr. 12, 1920.	6 w.	Unknown.

M. = months. W. = weeks. N. conf. = Normal confinement. M. & c. = Mother and child.

It is evident that myomectomy during pregnancy is a most satisfactory operation.

Clinical and Laboratory Notes.

A NOTE ON THE
SURVIVAL OF A PREMATURE INFANT UNDER ARTIFICIAL FEEDING.

BY P. T. O'FARRELL, L.R.C.P. & S. IREL., D.T.M. LIVERP.,

MEDICAL OFFICER, DUNLOP PLANTATIONS, LTD., MALACCA, FEDERATED MALAY STATES.

THE following case seems to be of interest in that the infant weighed 35½ oz. at birth, and was born during a malarial paroxysm, and also because of her progress under artificial feeding.

The mother, a multipara, aged 34, of pure European descent, married ten years, gave birth on July 20th, 1922, to a female child weighing 35½ oz.; the last day of the last menstrual period occurred on Dec. 24th, 1921.

Previous History of Mother.—Female child, full term, born in April, 1915; miscarriage at third month in 1919. During the previous two years the mother had suffered from a number of malarial attacks; some two months before her confinement she was in hospital for 21 days owing to attacks of malarial fever of more than usual severity; during paroxysms her blood had invariably revealed sub-tertian parasitic infection. On discharge from hospital to the date of her confinement she had been ordered 5 gr. euquinine with 2 gr. of pot. brom. four times daily.

Present History.—On July 20th, 1922, she developed a shivering attack and shortly afterwards labour-pains started; on examination first stage of labour was well advanced, the patient being in the hot stage of malarial fever with a temperature of 104° F.; 20 gr. cinchona febrifuge were given. Labour was uncomplicated and completed in about four hours with defervescence of the fever; normal head presentation. The puerperium was uneventful except that on the third day the temperature rose to 102°; the significance of this temperature might have been misleading had it not been associated with the characteristic signs of a malarial attack. The patient was ordered a liquid solution of quinine bihydrochloride, 10 gr. t.i.d., to be continued throughout the puerperium.

Condition of Child at Birth.—The weight was 2 lb. 3½ oz., the skin was wrinkled and of a markedly mottled appearance; sex characters (female) fully developed; no deformities or hernial protrusions. The child's head and body were wrapped in cotton-wool; on account of the evenness of the atmospheric temperature that exists in this district of the Federated Malay States (72° to 86° F.) the necessity of improvising an incubator did not arise; this factor no doubt contributed largely to the infant's survival.

Diet.—For the first 48 hours the child was spoon-fed with small quantities of Indian cow's milk well diluted; on the third day it was found possible to commence feeding with breast-milk, but the latter was very scanty. Feeding was carried out every two hours with the milk mixture and breast-milk alternately, until the sixth day, when the natural milk gave out. Breast-milk from other sources was unprocurable: thus, the infant was largely deprived of the full benefits of the immune bodies present in breast-milk and so necessary for defensive purposes.

Weight.—Weight at end of first week, 2 lb. 3½ oz. During the second week the milk mixture was continued; this gave rise to no alimentary disturbance, but it was apparent that the infant was not thriving; weight at end of second week, 2 lb. It was now decided to try one of the well-known, and much advertised, artificial dried milks; feeding was continued every two hours, 1 oz. liquid measure at each feed; in addition, minute quantities of cod-liver oil and malt were given; weight at end of third week, 2 lb. 2¼ oz. Progress was afterwards almost uninterrupted, as shown by the following increases in weight:—

End of week.	Weight.	End of week.	Weight.
4th	2 lb. 3 oz.	12th	3 lb. 8½ oz.
5th	2 ,, 5¾ ,,	13th	4 ,, 0 ,,
6th	2 ,, 8½ ,,	14th	4 ,, 4½ ,,
7th	2 ,, 7 ,,	15th	4 ,, 8 ,,
8th	2 ,, 9¾ ,,	16th	4 ,, 15½ ,,
9th	2 ,, 12 ,,	17th	5 ,, 5½ ,,
10th	3 ,, 0 ,,	18th	5 ,, 9½ ,,
11th	3 ,, 4 ,,		

There has been no vomiting at any time; motions are of good colour and consistency; flatulent distension has been rather a distressing symptom, but a No. 6 rubber catheter used as a rectal tube and regular abdominal massage have given much relief to this condition.

The late Prof. Budin and other authorities have shown the high mortality (100 per cent.) to be expected in premature infants under 3 lb. in weight, and further particular emphasis is laid on the necessity for breast-feeding if survival is to be hoped for at all in such cases. This case also appears to bear out the experiences of many observers in the tropics that quinine in ordinary therapeutic doses for malaria (5 to 10 gr. t.i.d.) can be taken with comparative safety during pregnancy without inducing labour; there is no doubt that in the case recorded above it was the malaria, not the quinine, that induced labour.

POST-OPERATIVE MANIA.

By W. J. Tyson, M.D. Durh., F.R.C.P. Lond., F.R.C.S. Eng.,
HONORARY PHYSICIAN, ROYAL VICTORIA HOSPITAL, FOLKESTONE.

CASES of post-operative mania, although comparatively uncommon, occur with such alarming rapidity that I think the following case is of interest:—

In July, 1921, I was asked by a surgical colleague to see a married woman, aged 45, with abdominal symptoms. The patient gave a neurotic history, and apparently was disappointed at being childless. The diagnosis was appendicitis; details are unnecessary. An operation was performed the same evening and an inflamed appendix removed. The wound healed rapidly aseptically.

About 36 hours after the operation the patient's mind began to wander; she quickly became maniacal, and within three days it was deemed advisable to remove her to a mental hospital. She remained there for over two months, and then returned to her home well; she has since shown no mental symptoms. Her recovery was gradual, but progressive and lasting.

Causes Assigned.—English medical and surgical textbooks contain practically no references to the condition, but American medical men, especially Kelly, have written a good deal upon the subject.

The causes assigned are many and various, and mostly unsatisfactory. Neither the severity of the operation nor sepsis apparently play any part in producing the mania. The anæsthetic, the giving of drugs, some form of intoxication, or physical or mental exhaustion, have been mentioned as causative agents. But nearly all authorities agree that a predisposition, hereditary or acquired, is present in every case. Nervous instability, nervous derangement, and nervous degeneration are the underlying physical facts of this insanity. The most common form of post-operative mania is that of confusional insanity, and after this, that of melancholia; the latter generally occurs at a later date in the course of the trouble, and the prognosis is not so good as in the former variety.

Duration of Disease.—The disease comes on between the second and tenth day after operation, and its duration is from two weeks onwards. The longer the mania lasts, the less is the chance of recovery.

Treatment.—It is necessary to consider the personal history in all cases, although, of course, when operation is necessary or advisable, the past history must not stand in the way; as already stated the seriousness of the operation does not seem to count in the production of this form of insanity. A large proportion of these cases recover comparatively quickly. It seems to me that if possible the patients should not be sent to mental hospitals; a certain stigma still attaches to such patients, and many of them might be sent uncertified into mental homes.

Comparative Cases.—Two other conditions produce mania, often acute and unexpected—viz., acute pneumonia and first cases of pregnancy—both interesting and often difficult of explanation. The mania in the above cases is entirely different in ætiology and onset from the delirium which may appear in an alcoholic subject after an accident or operation.

AN UNUSUAL CASE OF DRUG SUSCEPTIBILITY.

By H. H. Mills, M.D. Lond.

I RECENTLY prescribed linctus codeinæ co. B.P.C. in teaspoonful doses for a lady, aged 45, suffering from a mild bronchial catarrh with an irritable cough. She took three doses, actually having 2½ dr. from a 4 oz. bottle. Within 24 hours of the first dose an intensely irritable erythematous rash appeared on the head, thence spreading all over the body. Some 20 years ago the same patient suffered in a similar way after belladonna; also, on at least one occasion a similar rash followed a simple soap-and-water enema. The linctus codeinæ co. is in such common use as a safe cough mixture that I wonder if any of your readers can recall a similar case or throw any light upon the condition. Slight iodism and bromism are fairly common, and I believe quinine occasionally causes a rash. By the way, this patient had during previous days taken several doses of bromo-quinine.

Kensington.

DONATIONS AND BEQUESTS.—By will the late Miss Maria Louisa Jeffcock, of Worksop, Notts, left, among other bequests to Sheffield, £500 to her medical attendant, £1000 to the Sheffield General Infirmary, £500 to the Jessop Hospital for Women, and £500 to the Society for the Prevention of Cruelty to Animals.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

Exhibition of Cases and Specimens.

A meeting of this section of the Royal Society of Medicine was held on Jan. 12th, Mr. A. L. Whitehead, the President, being in the chair.

Retinitis Pigmentosa Sine Pigmento.

Mr. J. A. Valentine showed a case which he diagnosed as this condition, the patient being a man aged 26. His sight had been failing since 1915. No relatives had similar visual defect. There was 1 D. of hypermetropia in both right and left eyes. Ring scotomata were present, but the pupillary reactions were normal and the media clear. At night the patient had to concentrate his attention on the ground in order to find his way about, but the exhibitor did not think he had night-blindness in the proper sense of the term; his difficulty seemed to be due rather to the restricted central field of vision. The light vision was normal at the central point of fixation. No pigmentation could be detected.

Amaurotic Family Idiocy.

Mr. A. Levy showed a baby aged 19 months with this condition, the point of chief interest being that the parents were not Jewish, but English. The family resided in East London. This child had the typical discs, the peculiar cry, it had never learned to eat, and could not sit up by itself. The anterior fontanelle was still widely open, and it had been wasting for several months. The parents were first cousins.—Mr. Leslie Paton reminded members of a case of the kind shown in 1913 by Dr. Wilfred Harris and himself, also with a pure English parentage.—Mr. Treacher Collins said Sir Frederick Mott had shown that the ganglion cells of not only the cerebellum and cerebrum were involved in this disease, but those of the whole body.

Maculo-Cerebral Degeneration.

Mr. Montague Hine showed one of two brothers who were suffering from this condition. Defective vision was not improved by glasses, and the maculæ were seen to be very finely granular. The Wassermann was negative and there was nothing in the family history to suggest syphilis, nor was there consanguinity in the parents. The cerebral functions were now quite sluggish, he was almost paralysed, and had incontinence of urine.—Dr. Rayner Batten agreed with the diagnosis, but said the pigmentation was not so marked as in the other cases he had seen. This case and that of the brother belonged to the juvenile type, not the infantile. In the former type the disease always came on at about the same age—i.e., bordering on puberty. In one class pigmentation occurred without the cerebral symptoms.

Case for Diagnosis.

Mr. Percy Bardsley showed a young man, a theological student, whose complaint was that he quickly tired, and could not work more than five hours a day. The arteries and veins in the ocular fundus were remarkably bright. Based upon the blood examination, which showed 7,600,000 reds, and an increase in hæmoglobin, he regarded it as probably a case of polycythæmia rubra. The patient's liver and spleen showed no enlargement, and Wassermann was negative. The treatment recommended for polycythæmia rubra was venesection periodically, up to about 30 oz.

Hole in the Hyaloid.

Mr. Lindsay Rea showed a patient with this condition. The Wassermann was strongly positive, and after the proper antisyphilitic treatment, the bodies which had been in the vitreous began to clear. Sir William Lister had seen the case and confirmed the diagnosis.—Mr. Treacher Collins agreed with the diagnosis. Clearly the vitreous had been torn away from the optic disc, and where that had happened a circular hole had been left.—Mr. Gilblett mentioned two cases of similar kind which he had seen at the Ministry of Pensions, and in them the hole was four times as large as that in the present case.

Mr. Rea also showed a case of neuro-retinitis with detachment of retina in which a septic oral focus was found, and on this being treated and the patient sent to the seaside vision greatly improved, and the retinæ were becoming re-attached.

Unusual Results of Operations for Cataract.

Mr. T. Harrison Butler read an interesting paper in which he narrated a number of unexpected results after operations for cataract. In one case a serious hæmorrhage occurred when the preliminary iridectomy was done, and the patient's systolic blood pressure was found to be 200 mm. of mercury. In another case an exudate in the anterior part of the vitreous, possibly with some hæmorrhage, so simulated cataract that a preliminary iridectomy was done before the error was detected. Another case was one in which astigmatism after cataract extraction increased from 2·5 to 10, the only instance he had encountered in which the astigmatism had increased in this way. Several speakers commended Mr. Harrison Butler for relating these instructive cases.

The Treatment of Conical Cornea.

Mr. Charles Killick (Bradford) read a paper on this subject. He said he believed that keratoconus was not often seen in its earlier stages, but in strenuous work slight cases could easily be overlooked. Where doubt existed there should be a more frequent use of Placido's disc. His own experience of the condition had been when it presented a definite cone in each eye, when there was an opacity at the apex in one or both eyes, and when the vision was much reduced, usually below 6/60, though it might be improved to 6/24 by looking through a small aperture and by adding concave lenses. Sometimes unilateral cases were seen. One such developed suddenly in a lady, and did not vary over a period of several years. Death eventually was due to chronic tuberculosis. Treatment was almost always a question of surgical interference. Women were by far the more frequent sufferers from it. Of his six last cases, five were in women, including two pairs of sisters and a mental defect. This male was well developed and had never had good sight. He and one of the females had marked peripheral cataractous changes in both lenses. There seemed to be a tendency for it to occur in families. There had seldom been opportunities of microscopically examining eyes with keratoconus, but Parsons stated that Bowman's membrane was intact, but was thinned and wrinkled, Descemet's membrane being unchanged. Parsons gave the following main theories as to causation: relative increase of intra-ocular tension; malnutrition of the cornea, or inherent weakness of it; defective embryological development; disease of Descemet's membrane and epithelium. Ulceration or rupture of the cone had not been observed. The cornea was much thinned and might be reduced to one-third of the normal. The great difficulty was as to how to treat such an obstinate malady. The late Mr. Charles Wray said that in the early stages much might be done by general treatment, but the treatment laid down by him seemed too rigorous for hospital patients and required long rest for the eyes. In advanced cases, though general treatment could be added to the surgical, it could not be curative. In the case of the mental defect mentioned above Mr. Killick did not attempt surgery, therefore general treatment had to be carried out, and this resolved itself into the application of a firm pressure bandage and the administration of a tonic. This resulted in restoration of almost complete corneal transparency in a short time. He had seen the same result from it in other cases too. But it did nothing to bring about flattening. The chief operative methods were cauterisation of the cornea, with or without its perforation, combined, if necessary, with optical iridectomy and tattooing, cauterisation combined with sclerectomy, excision of the apex of the cone, or extraction of the lens. He had had only a limited experience of Critchett's target operation. Terrien said that cauterisation without perforation had never yielded him good results. Mr. Killick quoted a case of his own in support of this, that of a nurse, whom he first saw in November, 1920. She was aged 24 and in good health, but her eyes had not been right for the past four years. Vision was bad, and she had well-marked conical cornea in both eyes. He did first a sclerectomy in the right eye to establish hypotony. It was followed by iritis, hypotony, and a small macula on the cone apex, which soon disappeared as the eye recovered. The eye healed without leaving any obvious sign of fistulisation, and the corneal condition was not altered, nor vision improved. She returned to work, but eight months later came back asking for a further operation, as she could not see to do her work efficiently. The right eye had less than 6/60 vision, and the left had 7·00–6/36. He then tried the effect of performing the first stage of cataract extraction, making a large flap, in the hope that a pressure bandage and post-operative astigmatism might produce a beneficial result, but was again disappointed. Altogether six operations were performed, and later she was admitted to a sanatorium with her sight little improved. The following case, however, seemed to show that something better could be done. It was that of a married woman, aged 49, who had conical cornea, but not so markedly as the last case. Her sight had been gradually failing for 12 years. She had never worn glasses. She had conical cornea in both eyes, with a small opacity on the apex of the right, and there were marked peripheral opacities in both lenses. Vision was less than 6/60, and was not improved by glasses. General treatment was first tried, but a year later there was no improvement. On account of the lenticular opacities, he decided on simple extraction by the method of the subconjunctival bridge; the width of this bridge should be about one-third of the total incision. A good recovery ensued, and she was discharged after nine days with a fair amount of after-cataract. Later she was readmitted for discission to be carried out, and he succeeded in making an incision in the capsule about 1 mm. broad and ½ cm. long in the vertical diameter. He described the procedure in detail. Vision was found to be improved, and the patient left the hospital in September last with a quite transparent cornea, and was wearing −5·00 D. sphere, together with −1·00 cyl. axis horizontal, with which she could manage to read 6/24.

The paper was discussed by the **President** and Mr. **Elmore Brewerton**. The latter described the operation he did for conical cornea, making his crucial incision through the apex of the cone. The wound healed in two or three days, some degree of flattening ensued, and the patient saw over the centre.

SECTION OF PATHOLOGY.

A meeting of this section of the Royal Society of Medicine was held on Jan. 16th, Prof. **J. C. G. Ledingham**, the President, being in the chair.

Dr. **A. J. Eagleton** read a paper by Miss **E. M. Baxter** and himself on the

Serological Classification of B. diphtheriæ.

Beginning with a historical introduction, Dr. Eagleton went on to describe the investigation, which he and Miss Baxter had carried out, of 346 strains of virulent *B. diphtheriæ*. The strains had been derived from a wide "catchment" area; 342 of the strains had fallen into one or other of ten clear-cut groups, and amongst the remaining 16, at least 4 serological varieties had been encountered. Dr. Eagleton did not maintain that strains examined by different observers in different areas would necessarily fall into the same ten types which he had found—on the contrary, he would rather expect to find a multiplicity of types in existence. Some evidence was brought forward of a structural similarity between strains belonging to the different types. It was hoped that work along these lines would prove of value to epidemiology in the future.

Prof. **M. J. Stewart** and Dr. **J. le Fleming Burrow** (Leeds) described and showed specimens from a case of

Malignant Spheno-Occipital Chordoma.

The patient was a man of 30, who, after three years' service in France, was invalided from the Army for "phosgene-gas poisoning." When admitted to hospital on Nov. 28th, 1921, he gave a three years' history of cough, headache, occasional vomiting, and unsteadiness in walking. A year before he had complained of failing vision, and was found to have optic atrophy, most marked on the left side. Recently he had complained of weakness in the legs and in the right arm. When examined on Nov. 30th he had blurring of speech, cyanosis, and laboured respirations, with dysarthria of paretic type. Examination of the cranial nerves revealed blindness and primary optic atrophy of the left eye, with early atrophy and diminution of the visual field on the right side. The left pupil was large and immobile. The left third, fourth, and sixth nerves were weak, but not completely paralysed, and the remaining cranial nerves appeared normal. He made considerable complaint of pain and stiffness in the neck, especially when the head was flexed on the chest, but while the cervical and upper dorsal vertebræ were held rigid, there was no tenderness on percussion or on palpation. The cerebro-spinal fluid was normal in all respects, but was under slightly increased pressure. The patient's progress was steadily and rapidly downwards. The paresis of the legs and right arm increased, and was followed by loss of power in the left arm. The respirations were laboured throughout and the patient finally died on Dec. 5th, apparently of respiratory failure.

Post-mortem examination revealed the presence of an irregularly nodulated ovoid tumour springing from the central area of the base of the skull. It was completely covered by dura mater and was not adherent to the brain. On its inferior aspect it had extensively infiltrated and destroyed the central portion of the base of the skull—viz., the clivus, pituitary fossa, and subjacent parts. It did not appear, however, to have invaded the naso-pharynx. The tumour had led to great stretching, flattening, and distorsion of the mid-brain, especially the pons and crura cerebri, the optic tracts and chiasma, and, generally, the structures forming the floor of the third ventricle. The pituitary gland had been completely displaced from its bed and was flattened out on the antero-superior aspect of the tumour. The naked-eye and microscopic characters of the growth conformed to those of chordoma. The tumour was gelatinous, transparent, and very friable, especially in its deeper parts. Microscopically it was alveolar in structure, being broken up into masses of various sizes by narrow bands of fibrous tissue which carry the blood-vessels. The alveolar masses were devoid of both vessels and stroma. They were composed of epithelial-like cells, spheroidal, ovoid, and polygonal, and everywhere mucoid degeneration was in progress. To begin with, small droplets of mucin appeared in the cytoplasm, and as the cell grew older these increased both in size and in number until the typical "physaliphorous" appearance is seen. The next stage in the evolution of the cell was that the mucin droplets were discharged and might either flow together, forming homogeneous or granular masses of varying size throughout the growth, or might simply form a vacuolated, almost fibrillated ground-work breaking up the tumour tissue into little groups of shrunken cells. Both the intra- and extra-cellular droplets gave the staining reactions of mucin (polychrome methylene-blue, thionin-blue, &c.)

Some 40 cases of chordoma of clinical interest were now on record, and were about equally divided between the two seats of election of this tumour, the spheno-occipital and sacro-coccygeal regions. The small hernial protrusions of notochordal tissue from the clivus, called by Virchow "ecchondrosis physalifora," were probably much more common than this but could hardly be regarded as genuine neoplasms. Two examples of this condition had been met with in 150 specially investigated post-mortems. Virchow wrongly regarded these nodules as cartilaginous, and his term was a misnomer. The condition would be more correctly designated "Ecchordosis physalifora."

MEDICAL SOCIETY OF LONDON.

A meeting of this Society was held on Jan. 22nd, Lord **Dawson of Penn**, the President, being in the chair, when Dr. **Robert Knox** introduced a discussion on the

Clinical Results of Treatment of Malignant Disease by X Rays.

He said that this form of treatment had not been sufficiently long in existence for any true estimate of its efficiency to be formed. It was known that different tissues reacted differently to radiation, and that non-malignant growths were more vulnerable than malignant, and sarcoma more amenable to treatment than carcinoma. German workers had introduced the practice of regulating the dose of radiation according to the type of tissue or growth to be treated, each tissue having its own "biological reaction." Employing as the standard (100 per cent.) the unit skin dose (a dose which under certain standard conditions would produce a definite skin reaction) they estimated the biological reaction at the following percentages: Unit skin dose, 100; castration dose, 30; sarcoma dose, 60–70; carcinoma dose, 90–110; intestinal dose, 135. It would appear from these figures that malignant diseases could all be cured by a suitable dose of radiation, but actually there were many other factors influencing tissue change, so that only in a small percentage of cases a beneficial reaction could be expected; yet the results already attained were encouraging. Constitutional reactions in the patient must be carefully looked for; in the skin, the blood, and in the excreta. The dangers of X ray treatment included burns, toxæmia from the breaking down of malignant tissues, and blood changes.

Importance of Accurate Diagnosis.

In an attempt to estimate the value of the treatment of malignant disease accurate diagnosis was essential, and in this respect the possibility of syphilis mimicking malignant disease must be borne in mind. Dr. Knox related the history of a case which was exhibited to the Society in which X ray treatment was given for a supposed malignant growth of the tonsil with secondary deposits in the glands of the neck. In spite of treatment the glands ulcerated, and the man was admitted to the hospital in a collapsed condition from hæmorrhage. Under treatment with potassium iodide very rapid improvement took place, and what had appeared to be a carcinomatous ulcer of the neck healed completely. Another case diagnosed as "malignant thyroid," which recovered under treatment, was evidently another example of an error in diagnosis.

Results in Various Types of Case.

Cases of true malignant disease were quoted —a sarcoma of the naso-pharynx made a remarkable temporary recovery, the primary growth and secondary glands in the neck both disappearing with great improvement in the general health. The inevitable recurrence occurred later, and the patient succumbed to the disease. A case of epithelioma of the tonsil and pharyngeal wall also cleared up after treatment with X rays and radium, and enjoyed two years of apparent freedom from disease before recurrence took place. Further treatment of this case produced remarkable sloughing of the tissues, ascribed by the speaker to the previous radium treatment. A case of sarcoma of the testicle operated upon two years before and almost moribund from secondary growths in the liver and upper abdomen recovered for a year under intensive treatment, and was able to resume his occupation before he succumbed. A patient who had an intrinsic carcinoma of the larynx, which was verified by section, and had responded well to treatment was exhibited. Carcinoma of the œsophagus treated with X rays and radium gave a temporary improvement. Carcinoma of the stomach did not respond well, nor did similar tumours of the colon and rectum.

Dangers of X Ray Treatment.

These cases were quoted in order to show that remarkable effects could be produced by X rays and radium; a large number of inoperable cases had received much benefit, although the percentage of cures was very small. So powerful an agent must on occasion do, and had in some of his cases done, considerable harm; skin burns of great severity had occurred and damage had been inflicted on the pleuræ and lungs. Deep radiations to the upper abdomen had been followed by severe symptoms out of all proportion to the dose given. He had therefore made a practice recently to give a small preliminary dose to ascertain the patient's reaction before giving the fuller doses now employed. It was a question whether it was not advisable to divide the large dose into six sittings with an interval of a day or two between each. This method was being tried at the Cancer Hospital and was giving satisfactory results. A malignant goitre treated on these lines at nine sittings spread over six weeks made very great improvement as regards ability to swallow and slept better, but developed symptoms thought to be due to thyroid insufficiency, for which thyroid extract was given. Intractable diarrhœa set in and she died in a week. At the autopsy the thyroid was found to be much reduced in size, and the secondary glands in the neck reduced apparently to tough fibrous tissue, but there were malignant deposits in the peritoneum and abdominal lymphatic glands.

The position of X ray therapy as a prophylactic agent after operation for cancer was well established. Dr. Knox quoted cases where recurrences after operation had been dealt with, and the patients kept alive and well for as long as 15 years.

The New and Older Methods.

The new method of massive doses had not been in use long enough to enable its ultimate results to be compared with those of the older form of radiation, which had given satisfactory results. The use of more penetrating rays and bigger dosage produced more rapid results, but was more uncomfortable and risky for the patients and could not be employed unless their general condition was good.

Dr. **Knox** did not consider that X ray treatment could replace surgery, which should be the first recourse for operable cases, but thought that it formed a very useful adjuvant to surgical treatment of malignant disease and alone was very helpful in prolonging life and making it more comfortable in inoperable cases. He concluded by exhibiting a number of lantern-slides showing the results and complications of this treatment.

Discussion.

Mr. **Sampson Handley** described the results of X ray treatment in a few cases. A sarcoma of the umbilicus was apparently cured by X rays, but the large burn left had to be treated surgically. He was grateful to the radiologists for their willingness to treat and ability to help hopelessly inoperable cases of malignant disease, and described two cases of this kind which derived much benefit from the "Erlangen" form of treatment.

Importance of Patient's General Condition.

Dr. **Reginald Morton** had devoted himself exclusively to this branch of radiology for two years, but could not yet express any definite claims for X ray treatment; 95 per cent. of the cases he treated were hopeless cases from the surgical standpoint with extensive secondary deposits, so that very few cures could be expected. Further, in cases apparently more hopeful, the most careful examination could not always detect secondary deposits at a distance from the primary growth. The modern treatment required the collaboration of nature in dealing with the malignant deposits after they had been devitalised by ray treatment, so that it was of the utmost importance that the patient's general condition should be good at the time of the radiation. The presence of sepsis in the growth he considered a definite contra-indication to this form of treatment. He believed that when conditions were favourable a full dose at one sitting was more beneficial than repeated fractional doses. As regards results, he wished to say that the extravagant claims made for this form of treatment were not made by those responsible for its execution, who were nevertheless satisfied with the results already obtained and hoped for further improvements from better technique. Already they had almost overcome the danger of X ray burns of any severity by using several ports of entry where a massive deep dose was required. The fall in the red blood cell count after treatment in two cases averaged about 5 per cent. only, and the new technique had resulted in a lessened incidence of vomiting, which was never severe now.

Relative Vulnerability of Cancer and Normal Cell.

Mr. P. **Lockhart-Mummery** pointed out that the cancer cell was a very little more vulnerable to poisons than the normal cell, and thus it came about that occasional cases of the cure of cancer by drugs such as arsenic had been reported; these cases were favourable in the sense that while the normal cells had a high tolerance to the drug in that individual the cancer cells must have been vulnerable. The margin of difference was very small, however, both for poisons and physical agents such as X rays, so that any treatment designed to kill a cancer must come near the point of killing the normal tissues. His experience of the modern X ray treatment was limited to a few cases, but of these one died and two had very severe burns as the result.

Dr. **Gilbert Scott** maintained that cases should not be assessed as cures or failures, but that much was done by X rays as palliative treatment. The technique usually aimed at destruction of the primary tumour and neglected the various channels of dissemination. When giving prophylactive treatment after operation for cancer of the breast, for instance, he exposed large areas of the front and back of the trunk to radiation. Much remained to be worked out yet, such as the variation in response in different persons and the late reactions.

Dr. **Douglas Webster** said that X ray treatment had two aims, curative and prophylactic, and attained its greatest success in the latter, and especially in the case of superficial growths. The common causes of failure were insufficient extent of exposure, too small dosage, and inadequate observation after treatment. Prophylactic treatment after operation for cancer of the breast was not universally thought to be helpful; in some parts of Germany, for instance, it was considered to have made the results worse.

Mr. **Gordon Taylor** was a believer in prophylactic X ray treatment; all his cases of breast cancer received such treatment. He had been disappointed with the results of the temporary implantation for a few hours of small doses of radium in the wounds of operation for cancer of the breast, as it had appeared to cause severe shock, in one case fatal.

Dr. J. E. A. **Lynham** had seen severe sickness and violent reactions follow the treatment at Erlangen, and therefore decided to adopt the fractional method in his work with Dr. Knox at the Cancer Hospital, and this method had yielded results at least as satisfactory with less risk and discomfort to the patient. He had remarked that cases which were going to do well began to look and feel better within a few days. The effects of X rays were shared by the surrounding cells and the individual as well as by the tumour itself, and on the degree to which the reaction of the surrounding cells were stimulated to fibrosis the results largely depended. He believed in prophylactic treatment, but thought it should be deferred until six to eight weeks after operation.

Dr. **Knox**, in reply, said that much of the advertisement of the "Erlangen treatment" was due to the manufacturers of apparatus and the lay press. He had never known severe shock follow the small dosage of radium used by Mr. Gordon Taylor.

MEDICO-LEGAL SOCIETY.

A meeting of this Society was held at 11, Chandos-street, London, W., on Jan. 16th. In the absence of the President, Earl **Russell** was in the chair.

Prof. **Harvey Littlejohn** delivered a note on the

Microspectroscope in the Detection of Blood.

He said that in legal cases many tests of stains suspected of being blood were employed. These included the microscopic examination for red corpuscles and the hæmin test, but none provided so delicate a test as the microspectroscope; yet the use of this instrument was not described in the books on forensic medicine. If the suspected stain were on clothing a single strand of the material bearing a minute fragment of the stain was moistened and focussed under the microscope and the spectroscopic attachment then fitted. The characteristic two absorption bands of oxy-hæmoglobin would then be seen if the stain were blood; if any doubt existed the bands could be compared with those of a solution of fresh blood. Further confirmation could be obtained by reducing with ammonium sulphide and observing the spectrum of hæmoglobin; the spectrum of hæmochromogen could then be obtained by treating with potassium hydroxide. The results could be again confirmed by similar treatment of the fresh blood solution. A very old stain would give the spectrum of methæmoglobin. Prof. Littlejohn pointed out that these tests were extraordinarily delicate—the spectrum of hæmochromogen, for example, could be obtained from a crystal only visible under moderate power of the microscope. Even when the blood had been destroyed by heat it was still possible to obtain the spectrum of alkaline and acid hæmatoporphyrin. The only disadvantage of the test was the cost of the microspectroscope, which was considerable. A moderately efficient substitute could be contrived by replacing the eye-piece of a microscope by a small spectroscope, such as was used in the physiology class. The speaker had found it possible to mount and preserve slides of the various pigments for purposes of comparison, some of which were exhibited under the microspectroscope.

Sir **William Willcox** agreed as to the value of the instrument in medico-legal practice. The microscopic detection of red blood cells was exceedingly difficult in an old stain and the hæmin test required a fragment of dried blood for its easy performance. He added that the instrument could be used for the detection of blood-pigments in solution, but it was impossible to determine from its use alone that the blood was human or even mammalian.

Mr. J. **Webster** referred to the poor solubility of old stains in which only two spectra were obtainable. He thought that the hæmin test should always be employed; for the success of this test the acetic acid used must be truly glacial.

Exhibition of Specimens.

Dr. T. H. G. **Shore** exhibited the heart of a woman of 28 years who had called in a doctor on account of pain in the chest. Beyond the fact that she was five months pregnant the doctor could not discover anything, but the post-mortem revealed a rupture of the aorta through which blood had passed by dissecting between the coats into the pericardium. From the fact that this severe lesion had occurred so early in life he suspected syphilis. He also exhibited the kidney of a sailor who died within an hour of sustaining a burn from the breaking of a bottle of lysol which he was carrying in a trouser pocket.[1] The organ was swollen and intensely engorged. A third specimen was the scalp of a girl completely avulsed from eyebrows to nape of neck by revolving machinery. The girl was still alive and he was considering the possibility of tanning the scalp for use later as a wig.

Prof. **LITTLEJOHN** had seen specimens of rupture of the aorta, but none showing the transverse tear in the specimen exhibited, which was very unusual. He thought it would be possible to make an efficient wig from the scalp shown, as one had been preserved for 50 years in his museum and the hair was now only slightly bleached.

Dr. **M. I. FINUCANE** inquired on what grounds death was attributed to lysol poisoning in the case from which the kidney was obtained.

Dr. **SHORE** replied that there was no previous evidence of kidney disease and that the mode of death was typical of lysol poisoning.

Sir **WILLIAM WILLCOX** pointed out that many persons showed intolerance to carbolic acid; he had seen carboluria from 1 per cent. carbolic acid fomentations. The basis of lysol was carbolic acid, and it also contained an alkali which would increase the rate of absorption through the skin, so that there was no difficulty in explaining the rapid death in Dr. Shore's case.

Sir **BERNARD SPILSBURY** showed the skull of a woman in which there were five fractures due to blows from a blunt instrument, two of them showing impressions corresponding with the pattern of the head of the poker with which they were inflicted. Another specimen was a slice of liver of a woman who had been addicted to alcohol for many years; the organ was much enlarged and showed extensive fatty infiltration. A microscopic preparation stained for fat showed the most extreme fatty change.

Sir **WILLIAM WILLCOX** said that the liver exhibited showed that alcohol could on occasions act as a very powerful liver poison, producing the symptoms of deficient liver function and persistent vomiting. In one such case the discovery of arsenic in the urine had led to the suspicion of foul play until the speaker had analysed the organs and found no arsenic; the changes in the liver in this case were also due to alcoholism.

Sir **BERNARD SPILSBURY** said that death was not due to acute liver poisoning in this case, but to exposure from falling out of bed while under the influence of alcohol.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Jan. 4th, Mr. **A. J. HUTCHISON**, the President, being in the chair, when Dr. **H. T. CUBBON** read a paper on the

Use of Diathermy in Surgery.

He gave a general outline of the physical effects produced by the passage of the diathermy current through the body, with special reference to the destruction of morbid tissue by the heat produced. Specimens of meat were shown in order to demonstrate this.

The advantages of diathermy over ordinary surgery were discussed under the following headings: 1. Lack of primary hæmorrhage. 2. Absence of shock. 3. Absence of pain and the relief of pain in palliative operation. 4. Diminished risk of cell-implantation. 5. Sterilisation of the parts operated upon by the heat produced. 6. The scar resulting from diathermy is firmer, denser, and more pliable than the ordinary scar, with less tendency towards breaking down. 7. As the method of choice in patients too old or feeble for operation by other methods. 8. The patient is more willing to undergo further applications should they be necessary than he would be to submit to further cutting operations. This is due to the simplicity of the operation and the few after-effects. 9. Rapid convalescence. The complications which might arise after diathermy operations included œdema and risk of obstruction in laryngeal operations and the risk of secondary hæmorrhage.

Dr. Cubbon held that there was a wide field in which diathermy was capable of application. Practically all cases of malignant disease involving the tongue, the floor of the mouth, palate, fauces, and certain parts of the pharynx, vagina, and vulva are suitable for diathermy. He also held that diathermy would be found to be an excellent method of destruction in many cases of non-malignant disease where destruction of tissue was desirable. Fibromata of the naso-pharynx, papillomata of the bladder, cavernous nævi of the tongue, lips, pharynx, and buccal mucous membrane were cited as non-malignant pathological conditions which could be destroyed by diathermy with excellent results. He said that warts and small pigmented areas of skin could be effectively destroyed by diathermy sparks; strictly speaking, this was not diathermy, but the sparks produced by the diathermy auto-condensation method were so much less painful than the older high-frequency sparking that very often tissue could be destroyed without the use of a general anæsthetic.

Most of the cases of malignant disease which had been operated upon by diathermy were those which had been considered inoperable from the ordinary surgical standpoint. These cases had been naturally far advanced and cures could not be expected, but in spite of that the results had been distinctly encouraging. In operating on all early cases of malignant disease of the mouth and upper air-passages diathermy should be considered the method of choice, in view of the advantages which it possesses. Diathermy was no more a specific for the cure of malignant disease than surgery, but he was convinced that a combination of the two would be a tremendous help to the surgeon, and that diathermy in the future will be the most efficient way of dealing with malignant disease in the early stages, in certain parts of the human body.

Mr. **M. FITZMAURICE-KELLY** showed four cases, all of which had been successfully treated by diathermy by Dr. Cubbon and himself.

Mr. **ROBERT SANDERSON** read notes of a case of Subinvolution of the Uterus and of a case of Malignant Annular Stricture of the Colon.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.

A MEETING of the London Association of the Medical Women's Federation was held at the Elizabeth Garrett Anderson Hospital on Jan. 15th, Dr. **LOUISA MARTINDALE**, the President, being in the chair, when Dr. **ESTELLE COLE** read a paper entitled

The Psychology of Freud and its Application.

She defined certain basic ideas of the Freudian psychology and the use of the terms "conscious," "preconscious," and "unconscious," and spoke of the biologic, non-moral aims of the individual which are expressions of the unconscious. These aims are at war with the morality of civilised society and so are repressed, the continual warfare between "I want to" and "I must not" giving rise to what is called a conflict. The speaker emphasised the Freudian doctrine of psychical determinism or the causal determination of ideas and symptoms. Stress was laid on the wide interpretation of the term sexual, which has been introduced by Prof. Freud, and a description of the Œdipus complex was given. Complexes are, in Freud's opinion, at the root of all or nearly all neuroses. She described the dream as the preserver of sleep, and showed that the pictorial representation or symbolism of the dream is not the confused jumble that it appears on superficial examination. The Freudian method of analysis, leading to abreaction, was then described, and a list of abnormal conditions known to have been benefited by analysis was given. Notes of a case of neurasthenia with anxiety neurosis, which was cured by the method, were detailed.

---

[1] Full details of a fatal case of absorption of carbolic acid through the skin were recorded by Dr. W. R. M. Turtle and Dr. T. Dolan in THE LANCET of Dec. 16th, 1922.

Reviews and Notices of Books.

CLINICAL TUBERCULOSIS.

Vol. I.: Pathological Anatomy, Pathological Physiology, Diagnosis, and Prognosis. Vol. II.: Complications and Treatment. Second edition. By FRANCIS M. POTTENGER, A.M., M.D., LL.D. With a chapter on Laboratory Methods by JOSEPH E. POTTENGER, A.B., M.D. London: Henry Kimpton. 1922. With 105 text illustrations and charts, and 6 plates in colours in Vol. I.; and 65 text illustrations and charts, and 4 plates in colours in Vol. II. Pp. 707 and 725. £3 15*s*.

A CLUE to the spirit in which this work is conceived and written is to be found in its dedication to Sir James Mackenzie, Ludolf Krehl, and George W. Crile. The author has not been satisfied with the dogmatic statements of the average text-book, but has tried to explain the reasons underlying his views and to teach treatment from a physiological standpoint. This is perhaps the ambition of most writers of scientific works on medicine, but it is rare to find it as fully realised as it has been in this case. When, for example, the author discusses the blood pressure in tuberculosis, he is not satisfied with the bald statement that the blood pressure is low in tuberculosis; he debates at considerable length the various factors concerned with the maintenance of blood pressure in health, and shows why and how digitalis may be employed in combating this effect in tuberculosis. Naturally, in so large a work there must be parts with which the author's fellow specialists will not agree, but opposition and criticism become inevitably softened by the author's facile and eloquent method of exposition, and by his conscientious discussion of the observations which have given rise to the faith which is in him. His essay on graduated exercise is prefaced by the all too evident truth that ". . . . injudicious exercise or exercise at a time when it should have been avoided has been responsible for the death of more tuberculous patients than any other measure." With regard to the dangerous symptoms which may follow even graduated exercise, he thinks that some of them, such as slight rises of temperature and headaches, may be due rather to storing up of lactic acid in the system than to increased auto-inoculation of tuberculin. The success of graduated exercise must at any rate depend primarily on the person who supervises it. The author takes the same sensible line with regard to sanatorium treatment. Sanatoriums may, indeed, ". . . . stand as monuments, silently teaching the principles of regulated living in the open air," but the sanatorium is, after all, only an instrument for carrying out the ideas of the chief medical officer on whose personality everything hinges.

It cannot be honestly said that all the important advances made since the publication of the first edition reviewed in THE LANCET (1917, ii., p. 607) have been incorporated in the present edition. To be sure, a new chapter has been added on the relation of influenza to tuberculosis, but practically no attempt has been made to digest the recent literature of this particular subject. His personal experiences have convinced the author that influenza not only stirs latent tuberculosis into activity, but also gives a rapidly progressive character to the disease in many cases. The value of the chapters on treatment varies greatly. The author combines advocacy of tuberculin with sobriety of judgment, and the many pages devoted to this subject are well worth studying. With regard to the mechanical treatment of pulmonary tuberculosis by such measures as artificial pneumothorax and thoracoplastic operations this book is disappointing. It is difficult to estimate the author's knowledge of the latter, for he does not even mention them, and his discussion of artificial pneumothorax betrays considerable ignorance. A useful feature is the inclusion of more than a hundred pages of case-notes. Notes on individual cases are usually dull, but these are chosen so judiciously, and edited with such care that they give a maximum of instruction with a minimum of boredom. Incidentally, they impress the reader with the importance attached by the author to inspection and palpation which may alone provide the clinician with adequate data for an accurate diagnosis.

As we have suggested, there is a good deal of recent knowledge about tuberculosis which is not even referred to in either of these volumes, each of which weighs about four pounds, but it is doubtful if any other single work on tuberculosis contains so much useful information. The time seems to have passed when knowledge of tuberculosis was so limited that it could be satisfactorily condensed by one man into one book.

PROGNOSIS.

An Index of Prognosis and End-Results of Treatment. Third edition, revised and enlarged. By Various Writers. Edited by A. RENDLE SHORT, M.D., B.S., B.Sc. Lond., F.R.C.S. Eng. London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd.; Bristol: John Wright and Sons, Ltd. 1922. Pp. 594. 42*s*.

THIS index forms a valuable addition to the meagre literature on the subject of prognosis; the present edition, the third since 1915, has been brought well up to date. The section on venereal diseases has been rewritten by Colonel L. W. Harrison, that on gynæcology by Mr. Eardley Holland. A new section on ophthalmology has been contributed by Mr. Arthur D. Griffith. The valuable monograph by the late Sir Thomas Clouston, which was addressed to the old classification of mental disease, has been retained unaltered, for it is considered that there is insufficient data for discussing prognosis under the new nomenclature. The contributors have done a vast amount of work and taken great trouble to produce as complete a reference to the end-results of treatment as is possible, and the practitioner will find the volume a valuable aid in an important and difficult branch of medicine.

Allgemeine Prognostik. Second and enlarged edition. By Prof. T. BRUGSCH. Berlin and Vienna: Urban and Schwarzenberg. 1922. Pp. 623. M.3240.

THE first edition of this book, which consists of an account of our knowledge of individual constitution, was reviewed in THE LANCET three years ago.[1] The changes in the second edition are the result of further work on the subject. There is a general expansion, with the modification of the term "constitution" in the direction of that of "personality"; also we find added a discussion of psychical characteristics, of morbid heredity, and of E. Kretschmer's book on the correlation of personality with bodily conformation. An index has been provided. It remains a book for the philosophic general physician; the specialist will be independent of it. A protest may be entered against any more space being wasted in medical works on expositions of the elements of the Mendelian theory, for such are now obtainable in many easily accessible sources.

PERSONAL HYGIENE APPLIED.

By JESSE FEIRING WILLIAMS, A.B., M.D., Associate Professor of Physical Education, Teacher's College, Columbia University. London and Philadelphia: W. B. Saunders Company. 1922. Pp. 412. 12*s*.

THIS philosophic and high-minded book is written for college students, and all students should be encouraged to read it. It aims at improving the quality of human life by indicating what in life is worth while and what is not. A kindly optimism emanates from the whole book, and makes its reading a pleasure and an inspiration. The author is especially interesting where he deals with quackery in all its branches. He feels too keenly about this subject to pretend it is not a serious menace. The honest and outspoken attitude adopted by the author with regard to antivivisection, antivaccination, food-fads, patent medicines, occultism, osteopathy, chiropractics, Christian Science, and nostrums of all sorts, physical, mental, or moral, can do nothing but good. We praise his sense, admire his courage, and recommend his book to those numerous amateurs of medical knowledge whose refrain it is that the medical profession does little to warn them against the quack in his many disguises. We heartily congratulate the author on breaking away from the traditional text-book.

---

[1] THE LANCET, 1919, ii., 788.

PRÉCIS DE PATHOLOGIE MÉDICALE.

By M. JOURNÉ. Paris: A. Maloine et Fils. 1923. Pp. 1269. Fr.25.

THE title of the chair of "Internal Pathology" in the Faculty of Medicine was altered to "Medical Pathology" early in 1922. The subject-matter, however, remains the same and the present book would in this country be called a short text-book of medicine. It is a colourless compilation that will be of little value to English medical students, and it would be unfair to take it as representing the present state of medical knowledge in France. Anthracosis is described as the only pneumonokoniosis of importance; cancer is included under parasitic diseases; the page and a third devoted to the physiology of the lung are, with the exception of three and a half lines, occupied with an account of its supposed action in dealing with fats; mountain sickness is said to be caused mechanically by the lowered pressure producing a pulmonary congestion which overloads the right heart. Though this book was issued in November, 1922, the title page is dated "1923"—perhaps in the hope that these ideas may by the next year have become accepted truths.

SURGICAL DIAGNOSIS.

By H. C. ROMANIS, M.A., M.B., M.C. Cantab., F.R.C.S. Eng., Assistant Surgeon to St. Thomas's Hospital, Surgeon to the City of London Hospital for Diseases of the Chest. London: J. and A. Churchill. 1923. Pp. 302. 8s. 6d.

THIS little book is a condensed compilation of the teaching to be found in the best standard text-books of surgery. It treats only of diagnosis. It is readable, of convenient size for the pocket, and should be useful to the student in his ward and out-patient work.

HÆMOGLOBINOPHILIC BACTERIA.

Investigations into the Occurrence and Classification of the Hæmoglobinophilic Bacteria. By MARTIN KRISTENSEN, Chief of Department at the State Serum Institute, Copenhagen. Copenhagen: Levin and Munksgaard. 1922. Pp. 272.

THE author of this extensive monograph—the most comprehensive survey of the Pfeiffer group of bacteria which we have yet seen—is to be congratulated. It is the work of an expert bacteriologist, who sedulously chronicles his failures and doubts as well as his positive findings and sure results, and it will amply repay study on the part of all workers in bacteriology. The book consists of two parts: the first being a sound and critical review of existing publications on Pfeiffer's bacillus; indifferent work is not allowed unduly to encumber the author's argument for the sake of mere bibliographical completeness. This section closes with a summary of the question of the ætiological significance of the organism. The author stresses the lack of any constant pandemic type of organism through its wide prevalence in cases of the disease. The strains isolated, when critically examined, prove to vary so much, morphologically, biologically, and serologically, although within the limits of the group, that he considers it improbable that such diverse strains can be the causal agents of a single epidemic. From the evidence examined he concludes that "on the basis of what is already known about the occurrence of Pfeiffer's bacillus, it is reasonable to conclude that it is not the primary influenza microbe."

In the second half of the book the author describes his own work. He does not bring forward much that is actually new, but his numerous observations on a multitude of points are of great value in view of the large number of strains which he has examined. In the last chapter a comparison of Pfeiffer's bacillus, with other allied forms, gives a good deal of information which could not be obtained elsewhere without the examination of a very large amount of literature.

It is no small compliment to the status of bacteriology in the English-speaking races that such a monograph, published in Copenhagen and emanating from a Danish laboratory, should be printed in English, and we congratulate the author and publishers on its production.

EVOLUTION OF PUBLIC HEALTH NURSING.

By ANNIE M. BRAINARD. London and Philadelphia: W. B. Saunders Company. 1922. Pp. 454. 15s.

To record the history of public health or district nursing is to chart a series of efforts made by nurses, doctors, and philanthropic and public bodies from the time pity first aroused the desire to alleviate human suffering. Miss Brainard has had a wide field to cover. There was organised visiting of the sick under the Roman Empire; the Primitive Church established an order of Deaconesses; and the development of public health nursing to the stage when care of the sick in their homes is becoming a responsibility assumed by the community is admirably traced. Many failures to-day are attributable to ignorance of the past, and for this reason alone this book should be widely read. Miss Brainard has endeavoured to incorporate in her book the outstanding movements of international importance, which contributed by their influence to build up our modern methods of district and public health nursing. An interesting chapter on Kaiserwerth and the English Sisters reveals the part played by England, Belgium, Germany, France, and Switzerland in the attempt to organise a system of visiting nurses. This system is likely to develop still further in view of the shortage of housing accommodation, which makes even the middle-class public reluctant to import a resident nurse into a congested household.

The issue of the Visiting Nurses Directory (London: Scientific Press, Ltd. 1923. 9d.), to which we have already called attention, should facilitate the employment of visiting nurses by paying patients.

THE GOLD HEADED CANE.

By WILLIAM MACMICHAEL, M.D. A new edition, with an Introduction and Annotations by GEORGE C. PEACHEY, Author of "The History of St. George's Hospital." London: Henry Kimpton. 1923. Pp. 195. 18s.

As recently as Nov. 4th, 1922, we had occasion to review an edition of this medical classic published by the Oxford University Press containing an introduction by Sir William Osler. There is therefore nothing further to say about the text of the book now before us, but we can state that the introduction and the notes by Mr. Peachey are illuminating, though here and there we cannot see eye to eye with him. Thus, when he says on p. 4 that "the vaunted salubrity of Knightsbridge is perpetuated to the present time in the place-names of Constitution Hill and Montpelier Square," it seems to us that imagination has outrun discretion; again, on p. 30, when he remarks, "the Radcliffe Library, which is perhaps the most beautiful building in Oxford, . . ." the reader who knows Oxford will remember Magdalen College and the Divinity School. However, these are but matters of opinion, and we can thank Mr. Peachey without reserve for his annotations on ascertained facts.

Vertebrate Development.

Lehrbuch der Entwicklungsgeschichte. Second edition. By Prof. Dr. HERMANN TRIEPEL, Breslau. Leipzig: Georg Thieme. 1922. Pp. 211. 9*s.* 6*d.*

THIS book aims at giving the reader an account of vertebrate development. It is a student's text-book of small compass, and does not enter into questions of theoretical interest, but, as in other works of a like kind, dogmatic statements have to take the place, occasionally, of the qualified views which the author might have expressed with more space at his disposal. This apart, Prof. Triepel has written clear, short, and interesting accounts of the various aspects of his subject, extending from the sex-cells, through segmentation and gastrulation to the development of organs, and has managed to compress a great deal of information into his small volume. Presenting the German point of view, he does not always see eye to eye with our embryologists, but the work is nevertheless one which can be heartily recommended to those who wish to gain acquaintance with the general field of embryology of vertebrates in a reasonable compass. There are 173 clear figures in the text, but more use might have been made of explanatory diagrams. The book is well and clearly printed.

Herbals.

Old English Herbals. By ELEANOUR SINCLAIR ROHDE. London: Longmans, Green and Co. 1922. Pp. 243. 21*s.*

THERE will always be certain medical interest attaching to herbals, though the medical side is not developed in this book further than is implied by the inclusion of many notes on folk-medicine and references to popular beliefs in herbalism. Yet the whole story of herbals is covered, the historical arrangement allowing us to get a comprehensive view of the subject. The coloured frontispiece is a reproduction of an illustration contained in a twelfth-century transcript, and represents the digging up of herbs for medical purposes under the direction of a medicine-man or sage, the original being the Herbarium of Apuleius. The manuscript is in the possession of Eton College. Various chapters deal with herbals written in connexion with the colonisation of America by Spain and later by England, and here we find certain records of Red Indian plant-lore and learn also that many of our home weeds were introduced into America by the first colonists. The common complaint of gardeners, and especially of woodmen, is, of course, that American plants of inconvenient exuberance have been brought by returning colonists back into this country. It is interesting to note that tobacco was used by Red Indians not only in their religious ceremonies but as a medicine, and for a time the herb was believed to have a therapeutic value by our physicians, while surgeons employed it by enemas as an anæsthetic.

There is some dangerous material in this book for the imaginative charlatan. The oldest Saxon book dealing with the virtues of herbs (A.D. 950) is the Leech Book of Bald, the manuscript of which, from the fact that it was sheltered in Glastonbury, is to-day as good as when it passed from the hands of a loving scribe, who is reported to have been the personal friend of King Alfred. This book of 109 leaves has been described by one of our most learned medical historians, the late Dr. J. F. Payne, as "the first medical treatise written in Western Europe, . . . the embryo of modern English medicine." The book, which is not a treatise on baldness, contains receipts for that condition, for sunburn, and other cosmetic defects, for mistiness of the eyes, for the "flying venom," which appears to have been a phrase covering mysterious infections, for nocturnal visions, and for "water elf disease"—a very terrible visitation. Many of the remedies consist of infusions of common British plants such as yew, lupin, mallow, elder, strawberry, camomile, plantain, and dock, though in one case the herb which is directed for use must have been difficult to obtain; the prescription is protective against snake-bite, the direction being "if the man procures and eateth rind which cometh out of Paradise, no venom will hurt him." It is added: "Then said he that wrote this book that the rind was hard gotten."

We congratulate the author on an interesting volume, to whose production the publishers have given every care.

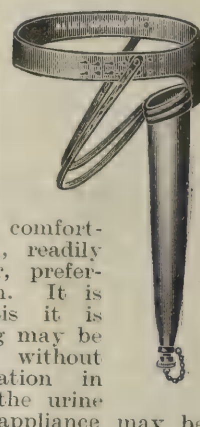
Précis de Phytothérapie. By HENRY LECLERC. Paris: Masson et Cie. 1922. Pp. 300. Fr.12.

IN these days of synthetic drugs, in which few galenicals remain and in which the active principles of these are known and may, any day, be manufactured artificially, it is refreshing to read a whole-hearted though well-balanced defence of the plant drugs of our ancestors. The limitation defined in the sub-title "Essais de thérapeutique par les plantes Françaises" brings us still nearer to our forefathers by cutting out recent tropical acquisitions. Without doubt in dropping many useless preparations we have in modern medicine let slip some useful ones. In France, where tisanes still hold sway and where the countryside is scoured for herbs to a greater extent than in England, this book approaches the position of a practical prescription book more nearly than it does with us. To us it is one of old time herbals brought up to date and with modern explanations where such explanations are possible. To the practitioner who knows his botany and who lives in the country it may well afford some interesting material for experiment.

New Inventions.

AN APPARATUS FOR COLLECTING URINE FROM FEMALE INFANTS.

THIS apparatus was designed to overcome the difficulties in collecting specimens of urine from small female infants. It was first used in the special ward for the investigation of infantile diarrhœa at the Children's Hospital, Great Ormond-street, and is now in use in the Children's Ward at Guy's Hospital and at the Infants Hospital, Westminster. It is most efficient in babies too young to sit up—the urine, however, being collected equally effectively in whatever position the child may be lying. The apparatus consists of a vulval pad or ring, oval in shape, which closely fits the perineum. From the vulval pad inferiorly hangs a conical bag, with a screw tap at the apex, and by its use single or 24-hour specimens of urine may be collected. It is comfortable, easily and rapidly applied, readily sterilisable either by boiling or, preferably, in 1 in 20 carbolic solution. It is washable. In cases of pyelitis it is extremely useful, in that the bag may be emptied through the screw tap without removing the pad. The variation in alkalinity or pus contained in the urine may be closely observed. The appliance may be used with even greater facility on male infants. In view of the simplicity of this apparatus, it can be applied by an intelligent mother, and we hope that it will prove as useful to general practitioners as it is under hospital conditions.



The apparatus is made by Messrs. Allen and Hanburys, 48, Wigmore-street, London, W. 1.

THE LANCET.

LONDON: SATURDAY, JANUARY 27, 1923.

THE RELATION BETWEEN THERAPEUTICS AND PHARMACOLOGY.

A certain over-trustfulness among practitioners, shown by a willingness to attribute peculiar virtue to remedies the administration of which has been followed by recovery among their patients, was the subject of attack at a meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine reported last week in The Lancet. A vehement endorsement of the criticisms, appearing in our correspondence columns, suggests that the relation of therapeutics to pharmacology, which is by no means so intimate as the union of these two branches of medicine into one section of a society would imply, needs serious readjustment. The art of therapeutics has remained considerably an art, too many of its principles being without sure scientific foundation, though the position has been vastly improved in recent times, and the best workers in this sphere of medicine are giving it grave attention. But the plight in which the practitioner may find himself is still somewhat comparable to that of a navigator before the science of astronomy was well advanced. He has to trust largely to his own ingenuity and his own interpretation of particular problems in many perilous situations. The medical profession wants a record of his experiences. Alas, the practitioner, with an over-full day, does not appear to realise that only the most careful records of cases that have been followed up, and collated with their similars, can advance the art of therapeutics on its scientific side. The progress of the sciences on which therapeutics must eventually be founded is dependent on the coöperation of the man who uses the weapons provided against disease. Over-eagerness to accept as efficacious preparations announced as physiological remedies may hamper that progress. In the course of the discussion at the Section of the Royal Society of Medicine it was said that organotherapy lags considerably behind endocrinology; would it not have been more correct to say that organotherapy has been exploited so far beyond what is justified by our present knowledge of endocrinology, that professors of the latter branch of science are driven to repudiate their own child?

It is not only in organotherapy, however, that the lack of coöperation between clinician and pharmacologist is evident. It was recently pointed out that the most popular official preparation of ergot in this country is one in which pharmacologists can find little, if any, active principle. Practitioners find it easier to credit anonymous pamphlets than to accept the view of physiologists that much of the activity which colloidal preparations of metals or other powerful drugs can possess may be attributable to the fraction present in true solution or to a protective substance added to ensure stability.[1]

If pharmacology and therapeutics were not mutually dependent, the lack of confidence between workers in either field would not be so serious. But, as Prof. A. G. Clark points out in the preface to a little book [2] expressly designed to bridge the gap between them, experiments upon laboratory animals usually show more or less the immediate effect of a toxic dose of a drug upon a healthy animal, whereas clinical medicine is concerned with the effects produced by therapeutic doses of drugs upon diseased human beings; such effects are usually produced only after many hours or days. Thus information derived from laboratory experiments requires to be controlled and extended by clinical observation. The question remains as to how a better understanding between groups of workers whose outlook and responsibilities differ so widely is to be achieved. We agree, and all will agree, with much that our correspondent, "A Physician," writes, but demur to his reproach of the clinician who lacks "the courage to use controls." It is more a question of temperament and of a conception of duty to each individual patient. To withhold treatment which he believes to be efficacious from 20 patients, whether suffering from intractable varicose ulcer or from syphilis, while he administers it in 20 parallel cases can hardly be regarded as a duty by a professional man who is treating patients, not conducting experiments. The attitude may be unscientific, but it cannot be condemned, unless, despite the absence of controls, results are published claiming to be conclusive. Even should controls be adequate, there are other variables which may easily vitiate clinical evidence. The typical impartial scientific observer is not popular or successful with patients, while the practitioner can hardly gauge the value of his own sanguine temperament. It is natural enough that laboratory workers who keenly desire to have their experimental conclusions tested in the sick room should be dissatisfied with the results, unclassified, uncontrolled, and insufficiently documented, which may emanate therefrom. But can they devise means whereby the action of a drug in clinical practice can be actually measured? The electrocardiogram is an example of such an instrument, and another designed to record the contractions of the uterus is being tried at Queen Charlotte's Hospital. Hitherto the clinician has not received sufficient consideration in a dual rôle; we are convinced that if his difficulties are recognised by his scientific colleagues attempts will be made towards the solution of joint problems in pharmacology and therapeutics which would soon have speedy results.

◆

THE PUBLIC AND TUBERCULOSIS RESEARCH.

Scepticism and modesty are the attributes of mind most conducive to useful research. It was William Harvey who counselled his fellows not to rely only on other men's traditions in the wonderful field of nature, where, he added, performance exceeds what is promised. "Nature her selfe must be our adviser; the path she chalks must be our walk. . . ." We note that the address by Prof. Lyle Cummins, printed at the front of our present issue, is frankly interrogatory. Instead of saying that what we "know not is not knowledge," he says: "Does what we know of tuberculosis deserve the name of knowledge?" Coupled with his call for research is the query, very pertinent in these days, whether every advance, real or illusory, should be published broadcast, as knowledge for the benefit of the public. The chief objection to this course is that apparent "advances" are often illusory; it is only necessary to consult an old edition of any popular work on therapeutics to realise how ephemeral some of these therapeutic "advances" have been. The treatment of tuberculosis of the larynx is a case in point. Less than a generation ago the tuberculous larynx was subjected to paintings with lactic acid and burnings with the electrocautery, on the assumption that the root of the patient's disease was being tackled. Now that we have come to regard tuberculosis of the larynx as an offshoot of a disease contracted decades earlier, the local applicationist appears like the gardener who tries to exterminate dandelions by electrolysis of their flowers, petal by petal. But though such examples could be multiplied indefinitely, Prof. Cummins may yet be right in his implied admission that the public is not only entitled to follow advances in science step by step, but may even contribute to such advances. That great layman, Lord Moulton, in making the methods of scientific medicine crystal clear in the courts and in the Upper House, may have contributed more to the advance of medical science than many doctors of medicine. Time and again we shall find that what we have taught the public was not knowledge, and that a recessional is humiliating, but at least we shall not be guilty of the obscurantism of our predecessors of the gold-headed cane. The acceptance of Prof. Cummins's epigram, "La santé est trop serieuse pour la laisser aux médecins," might not be the national calamity which its author believes. We cannot expect laymen to coöperate with us in medical research and preventive medicine and yet keep them like children outside in the dark till the Christmas tree has been lit; they want, quite naturally, to see the tree being lit, candle by candle. A little knowledge may occasionally be a dangerous thing; the housewife who asks her grocer to sell her a pound of vitamins may excite a smile, but she is at least a step ahead of her sister who is content to feed her family on canned foods. A remarkable feature of the sporadic health movement in certain parts of the United States is the prominence of the part played by laymen. In medicine as in law the common sense of the layman may prove salutary.

[1] The Colloidal State in its Medical and Physiological Aspects. By Sir William Bayliss. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1923. 6s. Also The Lancet, 1922, i., 40.

[2] Applied Pharmacology. London: J. and A. Churchill. 1923. 15s.

By a coincidence, some of the points raised by Prof. Cummins are answered in part by the annual report of the Medical Research Council, a brief summary of which was published in our columns last week. The section dealing with research in tuberculosis covers several pages and contains an account of research carried out in many places. In various departments of the National Institute study is being made of the pathology of general tuberculosis in young people, the relation of silica dust to industrial tubercle, the rate of metabolism in open-air treatment, and the changes in the gas of an artificial pneumothorax. At Cambridge Dr. A. Stanley Griffith is giving whole-time work to the differentiation of strains of tubercle bacilli, and in his last series of 132 cases of bone and joint tuberculosis he has found the bovine type in 13·6 per cent. At the Brompton Hospital Dr. A. C. Inman is studying the morphology and agglutinability of the tubercle bacillus. At the City of London Hospital Dr. Roodhouse Gloyne is investigating the primary sites of infection in young children. At St. Andrews Dr. A. Rowand is studying the early signs of tubercle in children, and at Glasgow Dr. H. L. Coulthard has completed an investigation of complement fixation in tuberculosis. This list is far from complete; other workers in various other places are giving whole- or part-time work to the study of some more or less well-defined section of the tuberculosis problem. It is satisfactory to note that some of this research is devoted to therapeutics. It may seem more logical to evolve treatment from ætiology, but sometimes it is possible to work back to ætiology from the results of treatment. The Research Council's report would have been still more helpful if it had given a fuller account of the central organisation—of its staff work. What machinery is there for keeping these comparatively isolated research workers in touch with contemporaneous investigations carried out elsewhere on the same subject? Have they to wait for such investigations to be published first in some foreign journal and then in abstract form in *Medical Science* before they can compare it with their own work? Are we in constant and intimate touch with Helsingfors, Tokyo, New York, and every other centre where research work is proceeding? It would be well if our own workers could be kept informed of what their colleagues abroad are writing and thinking.

Prof. Dreyer, whose work is referred to in the report, is making special inquiries in France, Norway, and Denmark about tuberculin tests in cattle. The information he thus obtains must be more reliable than if he had been rationed to the written word and had stayed at home. It has been said by a prominent clinician that if a really important remedy for tuberculosis were discovered its value would be universally recognised in a few years. The history of medicine tells another tale, and it does so because the world's staff work and liaison organisation in medical science have been imperfectly coördinated. It is largely for this reason that we do not even now know whether the steady decline in the death-rate from tuberculosis is the result of the direct campaign against this disease or not. But public interest and public coöperation are required to finance and organise international research.

INDUSTRIAL DISEASES OF THE EYE.

The recently published volume of Transactions of the Ophthalmological Society opens with the report of a discussion on industrial diseases of the eye, accidents, miners' nystagmus, and glass-blowers' cataract being excluded. It is satisfactory to hear from Dr. T. M. Legge, H.M. Medical Inspector of Factories, that amblyopia from lead poisoning, which used to be an important cause of industrial blindness, is now comparatively rare. Since 1900 lead poisoning has diminished by more than one half. In the years 1905–09 there were found 20 cases of optic neuritis from this cause; in the corresponding period 1915–19 there were only six. These results, he says, have been largely accomplished by the advance made in locally applied exhaust ventilation, by means of fans, to remove dust and fumes at the point at which they are produced, and so prevent inhalation of them by the workers. Before the war some cases were reported of amblyopia occurring in the manufacture of explosives in which dinitrobenzol was employed, but during the war blindness from this cause does not seem to have occurred. On the whole the risks of toxic amblyopia in connexion with industrial processes are now fairly well guarded against.

A further risk to the eyesight to which industrial workers are exposed concerns those working in excessive heat. It is comparatively recently that the danger of cataract has been recognised to exist for iron- and steel-workers from this cause. At present furnace-workers who acquire cataract are entitled to compensation under the Act. According to Mr. B. **CRIDLAND**, this form of cataract may be identical with that which affects glass-blowers, a saucer-shaped opacity at the posterior pole; at other times the opacity is more like a blot. The commonest variety is a wedge-shaped cortical opacity indistinguishable from the ordinary senile type of cataract, so that in assessing compensation there will certainly be ample room for differences of opinion. Besides glass-workers and iron-workers it appears that chain-makers and stokers are liable to this form of cataract. Still another aspect of the subject is approached by Mr. **BISHOP HARMAN** in connexion with myopia. He brings statistics to show that to the myope of more than a minimal degree (3 diopters) there is measurable danger to the sight in any employment involving prolonged application to near work, such as the employment of a clerk. From an investigation of the records of some 7000 private patients he found 480 cases of myopia whose history it was possible to determine; of these 183 were habitual close eye-workers and 297 were not. The percentage of breakdowns and damage to the eyes in the former class was 53, while that in the latter was only 9·4. From further figures he shows that the relatively bad prognosis for the myopic near worker is present even in those with so relatively a low average myopia as between 3 and 5 diopters. As we should expect, with those over 5 diopters it is far more decided.

This investigation is one of considerable importance, for, although there has been a general belief among medical men that short sight means weak sight, we know of no previous statistics with quite such a practical bearing. It may be said that the circumstances of a "breakdown" do not lend themselves to statistical analysis, and it would no doubt be well for others to investigate how far the figures brought forward by Mr. **HARMAN** can be confirmed. Whatever the original cause of myopia may be, its increase to dangerous dimensions is a matter well within the power of preventive medicine to influence. From the point of view of prevention of industrial diseases of the eye the choice of suitable occupations for myopes is a matter of the very first importance.

◆

VITAL STATISTICS FOR 1922.

THE Registrar-General has issued a provisional statement of the figures for birth-rate, death-rate, and infant mortality during the year 1922.

—	Birth-rate.	Death-rate.	Infant mortality-rate.
England and Wales.. ..	20·6	12·9	77
105 County Boroughs and Great Towns, including London	21·5	13·0	81
155 Smaller Towns.. ..	20·5	11·7	75
London	21·4	13·4	73

The smaller towns are those with an estimated population in 1921 of 20,000–50,000. The death-rate for England and Wales relates to the whole population, but that for London and the groups of towns to the civilian population only.

The Registrar-General remarks that the birth-rate of England and Wales as a whole is the lowest recorded, except during the war years 1915–19, while the infant mortality is actually the lowest on record. These provisional figures, which are not likely to require substantial modification, have been got out for the information of medical officers of health.

Annotations.

"Ne quid nimis."

WHAT IS A "PURE AND WHOLESOME" WATER?

EVERY authority responsible for a public supply of water is under statutory obligation to provide it in a "pure and wholesome" condition. It is obvious that Parliament draws some distinction between purity and wholesomeness, but this was in the period when little or nothing was known about bacteria and when the quality of a water was judged entirely from the chemical standpoint. A water may be considered pure chemically if it does not contain saline constituents which are objectionable either in quality or quantity and if it contains only the merest trace of organic matter. Unfortunately there are no tests which enable us to ascertain with any degree of accuracy either the quantity or character of the organic matter found in potable waters, and chemists must be satisfied with certain estimations giving an approximate idea of the quantity present. Frankland estimated the amount of carbon and nitrogen yielded by the organic matter, but the process was too tedious and delicate for general use. Later Wanklyn introduced his "albuminoid ammonia" process and Forchammer the "oxygen-absorbed" process, and both these are now universally adopted. Using these methods chemists are accustomed to pass a water, otherwise satisfactory, if it does not yield more than, say, one part of albuminoid ammonia per 10 million parts of water, and if at the same time the oxygen absorbed does not exceed one part per million. But nothing is known of the nature of this organic matter and experience indicates that a water yielding much higher figures may be perfectly wholesome; in fact there is no proof that, in the absence of objectionable bacteria, this organic matter is more deleterious than that contained in an infusion of tea. Few waters which the chemist passes as "pure and wholesome" contain more than a small fraction of a grain of organic matter. It is not unusual, however, to find that a water containing very little organic matter may come from a source liable to serious contamination, or that it actually contains bacteria indicating slight pollution with matter of intestinal origin. It may be chemically pure, yet bacteriologically impure and therefore dangerous or unwholesome. On the other hand, since the introduction of purification by chlorine, ozone, lime, &c., a water may be rendered sterile or at least free from any bacteria indicative of pollution and yet be chemically, judged by present standards, very impure. Can such a water be deemed "pure and wholesome"? Most would regard it as impure but wholesome, notwithstanding the apparent contradiction in terms. This is becoming a very important point, and Sir Alexander Houston, in a lecture given to the members of the Institution of Water Engineers, has defined a pure and wholesome water in such a way as to lead to the inference that a good sewage effluent carefully sterilised would constitute a "pure and wholesome" water. He defines such a water as water in "such a condition that it cannot cause typhoid fever, cholera, or other water-borne disease. It must also be free from chemical poisons and have no injurious effect on metals. Further, it should be bright, clear, and sparkling, free from suspended matter, reasonably soft, and the salts in solution should not be present in excessive amount." Organic matter might possibly be included in "chemical poisons," though it is exceedingly unlikely that the organic matter found in river waters and in part, at least, derived from sewage or manure is poisonous or even obnoxious in the small quantity found in such waters. A good sewage effluent rarely contains more than 2 or 3 grains of organic matter in the gallon, so that the amount found in streams which may be used as a source of water-supply must be and is undoubtedly much less. Unless, therefore, it is actually a strong poison or is a weak poison with a cumulative effect, the amount present in such a water which has been sterilised and carefully filtered can scarcely be harmful. Sentimentally there may be objections to the use of such a treated water, and chemists may object to its being designated as "pure," yet from the public health point of view it may be right to call it "pure and wholesome," but doubtless in some future legislation the question will be settled as to whether the designation can be accepted.

THE OPENING OF THE MAUDSLEY HOSPITAL.

THE Maudsley Hospital, 105, 107, 109, Denmark Hill, S.E. 5, will be opened formally by the Minister of Health, Sir Arthur Griffith-Boscawen, at 11.30 A.M., on Wednesday, Jan. 31st. This institution, the first of its kind to be opened by a local authority, owes its inception to the foresight and generosity of Henry Maudsley, who, in 1908, offered to the London County Council £30,000 towards the building and equipment of a hospital for mental diseases. His objects were defined as follows: The early treatment of acute cases of mental disorder, so as to prevent the necessity of sending them to county asylums; the promotion of research into the causes and pathology of insanity; and the provision of an institution where medical students might obtain good clinical instruction. The idea underlying Dr. Maudsley's beneficence is clearly indicated by a remark of his—namely, "There are not many natures predisposed to insanity but might be saved from it were they placed in their earliest days in exactly those circumstances and subject to exactly that training most fitted to counteract that infirmity." The war intervened to prevent the immediate development of the work along the lines of the original plan. Fortunately the time was not wasted, for on the initiative of Sir Frederick Mott the hospital became a valuable neurological clearing station. Now, after 14 years, Dr. Maudsley's far-seeing scheme comes into effective operation. Within the last few weeks we have set out some details of the accommodation provided[1] and of the courses of instruction.[2] We need only add here that the hospital has 137 beds, including 13 private rooms, and is under the medical superintendence of Dr. Edward Mapother. With teaching and research as part of its principal objects, the Maudsley Hospital is destined to do a great work.

PROPHYLACTIC URETHRITIS.

Dr. H. Bonnier and Dr. H. Rivoalen,[3] of Bordeaux, have given the name of "prophylactic urethritis" to the slight reaction in the urethral mucous membrane following prophylactic injections which have become so prevalent in the army and navy, especially since the war. All the substances employed for this purpose, such as the various salts of silver and mercury and permanganate of potash, are liable to cause this reaction, but if it is applied properly, prophylactic injection is followed by only a slight oozing which often escapes notice altogether. On the other hand, the use of caustic products, too strong solutions, or too frequent injections may give rise to a chronic urethritis, which is indistinguishable at first sight from gleet. The first symptoms of prophylactic urethritis usually appear within three or four hours, and never later than 24 hours after the injection in the form of a slight oozing from the meatus which may be preceded by a burning feeling in the urethra or a slight itching in the meatus, as at the onset of gonorrhœal urethritis, but, as a rule, is not accompanied by any subjective symptoms. The meatus may be a little redder than usual and slightly swollen, but usually shows no obvious external change. The urethra is supple and painless, nor is there any pain on micturition. If left to itself the discharge disappears in a few hours or at most in two days without staining the linen, unless use has been made of a solution of a silver salt which leaves an indelible black stain. The chief interest of prophylactic urethritis is due to a possible misinterpretation of the nature of the discharge. The doctor, mistaking it for the onset of gonorrhœa, may institute an abortive treatment by injection of a strong antiseptic solution which may give rise to a chronic inflammation of the urethra, prostate, and bladder. The distinguishing features of prophylactic urethritis, the knowledge of which should prevent those disastrous consequences, are of three kinds—clinical, cytological, and bacteriological. In the first place the discharge appears a few hours after the injection, which, as a rule, has been given within two or three hours after exposure to infection. It is usually colourless or yellowish, slightly sticky, less frequently milky in appearance, in which case it is indistinguishable from the discharge accompanying the onset of gonorrhœa. The cytological characters of prophylactic urethritis are its richness in epithelial cells and scarcity of polymorphonuclear leucocytes. In some cases, however, there is a very intense polymorphonuclear reaction, and no help can then be derived from cytological examination. Bacteriologically the discharge may be entirely aseptic or, on the contrary, show an extraordinary abundance of organisms consisting of various cocci and bacilli of the pseudo-diphtheria or *B. coli* type. Pseudo-gonoccocci not staining by Gram but distinguished from true gonococci by their irregular size and extra-cellular localisation are frequently encountered. It is obvious from this description that the prognosis of prophylactic urethritis is absolutely good, the only danger possible being due to its being mistaken for gonorrhœa and treated accordingly. Treatment consists in abstention from all active measures, especially if the discharge is sterile and non-purulent, while if there is an abundant microbial flora, the urethra should be washed out with an alkaline lotion, the injection being strictly confined to the meatus and adjacent part of the urethra.

THE MANNER OF MAN THAT KILLS.

THE subject of murderers and their punishment is unfortunately of topical interest. The plea of insanity is offered by counsel when there is any possible chance that it might be accepted. While it is obvious that some murders are committed with a definite motive by a sane person, the more interesting types of criminals are those who are not of normal mentality. In a recently published book[1] Dr. L. Vernon Briggs lays before us with minute detail the cases of Bertram Gager Spencer, Leon Czolgosz, and Clarence V. T. Richeson, who committed their crimes in America. His point is that in men such as these defectiveness or mental disease can easily be recognised early in their lives, that the condition of the three men he deals with was, in fact, recognised or recognisable before their crimes were committed, but that the neglect of society, and lack of organisation to deal with such subjects, left them free to kill their victims, so that ultimately six lives were needlessly sacrificed. In concluding his account of Richeson and his execution, he writes: "The penalty exacted by the laws of Massachusetts had been paid and all hope of studying this abnormal man for the purpose of aborting criminal tendencies in others of this kind was wiped out in a few seconds," and he asks, "Could anything have been more destructive to this branch of science? Could society have conceived any better plan to thwart the work of preventing the development of other men of this kind?" This appears to be a fair statement of the case on behalf of the alienist who is also a criminologist. No man who callously kills his fellow for a reason which would not induce most of us even to strike a blow can be regarded as "normal," and a large proportion of the persons whom we hang in this country are from this point of view abnormal. Richeson certainly was abnormal. Indeed, in this country a defence of insanity might well have been raised successfully on his behalf. It might have failed, but in any case he would never have been allowed to plead guilty and have been sentenced to death without trial. When we consider that the girl with whose murder he was charged drank poison in her own home, no doubt after she had obtained it from him, we realise that American criminal practice differs widely from our own.

[2] THE LANCET, Dec. 30th, 1922, p. 1407.
[3] Gazette hebdomadaire des Sciences médicales de Bordeaux, Dec. 3rd, 1922.

[1] The Manner of Man that Kills. Spencer—Czolgosz—Richeson. By L. Vernon Briggs, M.D., Director of the Massachusetts Society for Mental Hygiene, Member of the American Institute of Criminal Law and Criminology. Boston: R. G. Badger. Pp. 444. $5.

The other two cases are not such strong examples in British eyes. Spencer, in 1908–10, created a sensation at Springfield, Mass., by a series of burglaries and robberies, in which he exhibited daring and bravado. He had been known to threaten with violence and discharge a pistol when interrupted, but did not greatly enrich himself by his depredations. Finally he shot and killed a Miss Blackstone who was visiting friends, and was in their sitting-room with other women when he walked into it. It would have been very difficult to satisfy a British judge and jury that such a man did not know the nature and quality of his acts or that they were wrong, and he was duly tried and executed; but Dr. Briggs, by a most minute examination of his personal and family history, certainly establishes that he was a man who "had every right to be insane," if we may use the expression. His was a case where the antipathy of society for his act, and its result, caused a general approval of his fate; just as in True's case a like antipathy caused disapproval to be expressed when the Home Office, upon the report of its medical advisers, decided upon his reprieve. Czolgosz shot President McKinley on Sept. 5th, 1901, in the grounds of the Pan-American Exposition at Buffalo. He was tried on Sept. 23rd and 24th, and was electrocuted on Oct. 29th. There was certainly not much opportunity given to raise and support by evidence a plea of insanity at his trial, and no doubt there was a strong feeling on the part of the authorities that he must not escape the death penalty. We doubt if he would have escaped in parallel circumstances over here. He was not normal; it is difficult to conceive a normal person murdering the president of a republic or a sovereign merely because he thinks that sovereigns and presidents ought not to exist; but we doubt whether society at the present time would approve of such as he being maintained alive to be trained and studied, if their execution were thought likely to deter others from following their example. Dr. Briggs's book contains much useful matter for those interested in amending the legal test of insanity. A more difficult proposition than this for reformers would be to bring about the prevention of murders by the early recognition and treatment of such cases as he describes.

THE COPPER REACTION IN THE CEREBRO-SPINAL FLUID.

LUMBAR puncture as a means of diagnosis has become current among general practitioners, especially those who have to deal with children's diseases. The macroscopic characters of the fluid are in the majority of cases not sufficient in themselves to establish an accurate diagnosis, and further investigations of a chemico-physical and microscopical nature become necessary. It is here that the difficulties of the busy practitioner begin who has not at his command the necessary laboratory equipment and who may be at some distance from a centre where he can obtain it. A reaction which has been unduly neglected has been recently studied by Dr. A. Medi,[1] who finds reaction with sulphate of copper a method at once simple and practical and one in direct relation with the clinical facts and with the other chemico-physical reactions of the cerebro-spinal fluid and its microscopical characters. The method consists in taking 2 c.cm. of the cerebro-spinal fluid, filtering, adding three drops of each of Fehling's solutions, and boiling. According to Dr. Medi, this test always furnishes characteristic information for differential diagnosis—that is to say, the reducing substances shown by a yellow colour on boiling are not lessened in cases of toxic irritation, while there is scarcely any precipitation in cases of bacterial infection, and complete absence of reaction in meningococcic meningitis either in the first or subsequent punctures made during the acute stage. So much so, that an absence of reaction to copper solutions would justify the practitioner in having immediate resort to intrathecal injections of specific serum. Another important question arises in the diagnosis between serous meningitis and tumours on the one hand and tuberculous meningitis on the other; the most accurate clinical examination may be inconclusive, lumbar puncture may give rise to a clear fluid exuding under pressure or only by drops. The formation of a pellicle may be delayed for some hours and is not always pathognomonic, the amount of albumin may correspond to that of tumour or of meningitis. The sulphate of copper reaction in such cases gives abundant reduction in tumour and serous meningitis and always a diminished reduction in tuberculous forms. Information is also afforded by change of colour in the copper solution before boiling, which may remain blue or take on a deep amethyst tint. In 52 specimens of fluid examined by Dr. Medi he observed that fluids which took on a blue colour when boiled gave an abundant yellow or reddish-yellow precipitate; fluids with a faint amethyst tint gave less precipitate, which was greenish-yellow; while those with a deep amethyst colour did not give any precipitate. The fluids from the first of these series were from tumours, hydrocephalus, and serous meningitis; those from the second were from tuberculous meningitis, and those from the third from purulent meningitis. There are therefore two clues derived from the single reagent, one in the cold and the other after boiling, each acting as control to the other, and by their simplicity and practicability they should prove to be of great use in diseases of the nervous system, especially in children.

THE DIPHTHERIA "CARRIER" AGAIN.

WE recently dealt[1] with the problem of the diphtheria "carrier," which still awaits solution. Some observations on the value of bacteriological diagnosis were made by Dr. R. A. O'Brien at a recent meeting of the Metropolitan Branch of the Society of Medical Officers of Health. He pointed out that when the experienced clinician diagnoses a case as one of indubitable diphtheria the laboratory, in practically every instance, finds virulent bacilli in large numbers. In such cases as these the clinician was not aided by bacteriological diagnosis, while grave damage might result from treatment being delayed until the results of bacteriological examination were available. On the other hand, many patients who were free from diphtheritic infection and who would not be diagnosed by the clinician as suffering from that disease, were labelled as diphtheritic because cultures from throat swabs showed diphtheroid bacilli. Other cases were diagnosed as carriers on similar evidence. Dr. O'Brien thought the present position did not reflect credit on our public health system. Though he would not go so far as the American writer, who would abolish the whole system of laboratory diagnosis and entrust the diagnosis of diphtheria entirely to the clinician, he would go a great part of the way. Definite cases could be diagnosed clinically without swabbing, and cases not recognisable on clinical grounds should not, without further examination, be diagnosed from a swab unless the growth showed abundant Klebs-

[1] THE LANCET, Dec. 16th, 1922, p. 1289.

Löffler bacilli in the manner characteristic of the definite clinical case. Quantity and virulence should be considered, and he would not as a bacteriologist recommend the isolation of a carrier if the bacilli in the smear from an overnight culture were very scanty. The patient should not, he thought, be isolated until a virulence test had been applied, except in cases where the experienced clinician had made a definite diagnosis. Consulting experts were rapidly mobilised for such things as small-pox, plague, and encephalitis, and Dr. O'Brien suggested that it might be possible to have similar visiting consultants for notified cases of diphtheria, who would decide whether it was justifiable on the clinical evidence alone to remove the patient, giving an initial dose of antitoxin the while; otherwise a virulence test should be undertaken. In large centres of population the health authorities should, he thought, make available as full facilities for the virulence test as for the ordinary microscopical examination of overnight cultures. Hospital accommodation and money might be further saved by applying the virulence test in the hospital immediately after admission in all cases which were not diagnosed definitely as diphtheria on clinical grounds.

OBSERVATIONS ON SPINAL ANÆSTHESIA.

Mr. D. N. Kalyanvala has sent us some observations on spinal anæsthesia, a pamphlet reprinted from the *Edinburgh Medical Journal*. The foundation on which the observations are based is the small number of 81 cases; but these have evidently been carefully investigated, and if the author has no new facts to add, at any rate his observations provide valuable confirmation of some of the less commonly recognised phenomena of spinal anæsthesia. Much attention was given to the blood pressure of these patients. Mr. Kalyanvala does not employ the spinal method if the pressure is less than 100 mm. He approves highly of preliminary injection of narcotics, often procuring a genuine "twilight sleep" before the puncture. An illustration shows the author's instrument for recording the intraspinal pressure. He maintains that this bears no simple relationship to the arterial pressure. High blood pressure was noticed with low cerebro-spinal pressure, and vice versa. The author also states that there is no relationship between arterial blood pressure and post-operative headache or between this headache and the preliminary intraspinal pressure. He distinguishes two separate classes of headache after spinal injection, frontal and occipital, and refers the latter to meningeal irritation from the puncture. In a communication which we published last week, Dr. S. A. Lane claims that headache is infrequent when the combination is used of twilight sleep and spinal injection. The immediate use of the Trendelenburg position after the injection has been made appears risky, and sitting the patient up for injection when he is well under the influence of the hypodermics is certainly sometimes undesirable.

MELANOBLASTOMA OF THE NAIL-BED.

Dr. Arthur E. Hertzler,[1] of Halstead, Kansas, has given this name to a condition sometimes known as "melanotic whitlow," which is a malignant disease of the nail-bed marked by the formation of newly-formed tissue about the nail border and beneath the nail. The growth is characterised by the formation of melanin and a tendency to spread by the lymphatics. The condition is rare, barely 20 cases having been recorded, 15 of which Dr. Hertzler summarises, in addition to an account of two cases which came under his own observation. Local recurrence and lymph gland metastases have occurred in all the cases which have been followed long enough. Apparently all the patients die sooner or later of the disease, although some may remain free for as long as ten years. From similar lesions which Dr. Hertzler has studied in the lower extremity, he thinks it probable that early diagnosis and prompt amputation may produce a cure. X rays and radium, as in all forms of melanotic disease, are worse than useless. Histological examination shows a fringe-like arrangement of the tumour cells just beneath the epithelial layer, with little tendency to nest formation. Dr. Hertzler's cases represented a relatively early stage of the disease, both exhibiting the characteristic black border about the lesion without any involvement of the neighbouring lymph glands. In the first case, which occurred in a woman aged 64, the thumb was amputated 18 months after the onset, and the patient was still free from recurrence two years after the operation. In the second case, which occurred in a woman aged 54, the condition was first noticed by the patient four years before she came under observation. Amputation was performed at the midphalangeal joint, and healing took place without reaction. As the operation had been performed only two months previously, no recurrence was to be expected for some time.

WELFARE SUPERVISORS.

At a dinner given by the Industrial Welfare Society on Jan. 18th one of the directors, Mr. Robert Hyde, said that the pressing need of the moment was a training centre where men and women, temperamentally suited for the task of welfare supervision, might receive instruction in the technical details with which they would have to deal. He hoped that some public-spirited person desirous of contributing to the cause of industrial peace would come forward and provide such a centre.

The first attempt to provide systematic training for social work was made towards the end of last century, when the Charity Organisation Society and the Women's University Settlement instituted a joint scheme of study, which later developed into the London School of Sociology. In 1904 the University of Liverpool established a school of social science; four years later the University of Birmingham followed suit, and in 1912 the London School of Sociology became merged in the social and administrative department of the London School of Economics. Before the war broke out the Universities of Bristol, Glasgow, Leeds, and Manchester had started social study courses, a movement to which the war gave an unexpected stimulus. The demand for trained workers largely exceeded the supply, and in spite of a period of uncertainty following the war it is probable that the demand will keep up. The teaching given in these courses includes industrial history, social philosophy and service, economics, psychology, finance, ethics, politics, and internationalism. A certain number of visits are paid to hospitals and to labour exchanges to find suitable employment for individual cases. The average course is two years, and at the end of this time a social diploma can be obtained, but the training is largely theoretical, and can only form a groundwork for the knowledge required by a welfare supervisor actually working in industry. It is impossible in colleges to teach men and women how to handle their fellow-workers, a faculty which requires practical training under an able teacher.

We take it that this practical training is what Mr. Hyde would have established, and the only way in which it can be done is to draft the students into factories where welfare supervisors are already employed, and let them work in conjunction wth these teachers for a period. After such apprenticeship the welfare workers would be qualified to seek employment in any industry. They would have both theoretical knowledge and the practical knowledge of the regular methods employed in factories of dealing with human beings. Naturally, the details of a particular factory routine would have to be acquired by working in that factory. The present system of things is haphazard. The employer who contemplates for the first time having a welfare supervisor for his works, takes a man or woman with a diploma from one of the present training centres who has never seen the real workings of factory life, and that supervisor, although excellent in theory, is useless in practice. Naturally, there is mutual dissatisfaction. The whole need of present welfare workers is a sufficiency of factories where they can have their theoretical knowledge tempered by practical experience gained under an able fellow-worker.

THE NATURE OF BRAXY.

FOR hundreds of years there have been losses in the sheep flocks of this country, amounting in certain districts to 20 to 50 per cent. of the hoggets, from a disease with characteristic symptoms and a concise name—braxy, although little or nothing was known of its nature. Two accessible books of reference describe braxy as "symptomatic anthrax" and "plethora of the blood resulting from change of pasturage." Spasmodic investigations have been made into the origin and prevention of the malady, for which in turn the bacillus of malignant œdema and the bacillus of black quarter were held responsible. With the help of a Government grant and a research laboratory, S. H. Gaiger, F.R.C.V.S., and his assistant, T. Dalling, M.R.C.V.S., have since 1917 worked to elucidate the infective agent, and their results appear in the *Journal of Comparative Pathology and Therapeutics* for September and December, 1922. It may now be regarded as settled that the *vibrion septique* of Pasteur is the contagion of braxy. The primary lesion is situated in the fourth stomach where the vibrio produces a toxæmia which gives rise to serious changes in the kidneys and to a lesser degree in the liver and heart. Climatic conditions have much to do with the incidence of the disease, for frosted food in the rumen chills the fourth stomach and renders it liable to attack, especially when a change of weather from frost to mild or the reverse occurs. The choice of a preventive appears to lie between Jensen's sero-vaccine method and the toxin method. Mr. Gaiger is confident that in a few years' time a laboratory braxy preventive will be in general use.

MAX NORDAU.

THE death of Max Nordau, which occurred in Paris early this week, at the age of 74, would have attracted more notice had he died in middle age, when the most famous of his works on social maladies, *Degeneration*, was published. He was a medical man, but previous to graduation at the University of Buda-Pest, at the age of 24, he had already published stories, essays, and poems, and had been regularly connected with at least one great Austrian newspaper. Almost immediately after his qualification he spent six Wanderjahre, visiting all the great European capitals, and when he started in Paris as a physician he could show an equipment to analyse continental social life such as few can ever have possessed. Settled in the centre of French literary and social activities the early result was a daring book, *Conventional Lies*, in which he assailed practically the whole of modern civilisation as being founded on subterfuge. Its sequel, *Paradoxes*, contained an analysis of the machinery for the investigation of conventional lies, and in 1893 he rounded off his pessimistic theories of civilisation with *Degeneration*, a learned and mordant essay on the theme that genius and madness are allied, which was appropriately dedicated to Lombroso. In a totally different field—namely, in the promotion of Jewish national ambition, Nordau was also a leader, and here, as in his sociological work, we can trace the influence which his medical training always exercised over him. Much of what he did and what he wrote was bitterly assailed—he would not have had it otherwise—but there is no doubt that he was animated by a brave reforming spirit.

WE regret to announce the death of Mr. Hunter Finlay Tod, senior surgeon to the Ear, Nose, and Throat Department of the London Hospital.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

IV.

THE TREATMENT OF WHOOPING-COUGH.

Prophylactic Treatment.

1. *Isolation.*—Every case of whooping-cough should be immediately isolated and kept away from uninfected children for two months, or for 14 days after all paroxysms have ceased. Parents should be instructed as to the infectious nature of the disease, and particularly of the enhanced risk of infection when a healthy child is in contact with an infected one in a confined space. For this reason while the paroxysms last, and for 14 days later, infected children should be excluded from schools, clinics, omnibuses, trains, and trams. It may be desirable to get such a child away to the seaside or country, but precautions, such as a special carriage, which can afterwards be disinfected, should be taken. Particular care must be exercised in detecting and isolating those mild cases which often escape diagnosis; as a general rule, any child with a chronic or paroxysmal cough should be regarded as a case of whooping-cough if another member of the family is known to be affected with the disease. This rule applies especially to infant welfare centres, creches, and infant schools which, in the absence of strict precautions, may readily become converted into breeding-centres for disease.

2. *Immunisation.*—In the case of particularly delicate children, children with incipient tuberculosis, or the children of very anxious parents, an attempt to confer some degree of immunity may be made by giving a series of injections of vaccine of the type described below. The parents must be warned that immunity cannot be guaranteed, but that such treatment affords reasonable hope of minimising the attack and preventing dangerous complications.

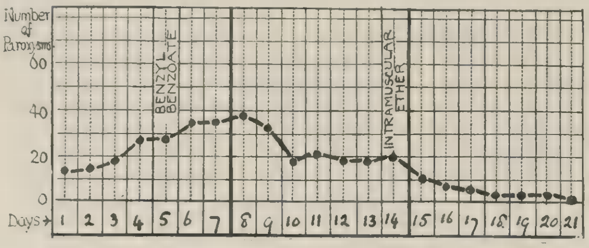
General Treatment.

1. *Hygiene.*—Exposure to severe weather must be avoided, but in uncomplicated cases there is no doubt that paroxysms are less frequent in the open air or in well-ventilated rooms than in hot and stuffy rooms. Dust and smoke even in minimal quantities may excite coughing, and provided that chill be avoided it is better that the child's temperature-regulating mechanism be exercised by adaptation to mild changes of temperature, than that his delicacy be increased by a perpetual artificial warmth. When going out of doors such children should be well clad, mothers should be discouraged from allowing them to have legs, arms, and necks exposed as they often are with modern clothing. At night flannel pyjamas afford a protection to the restless child who is apt to throw off his bedclothes.

2. *Dietetic.*—Nothing is more important in the treatment of whooping-cough than the diet. The disease is a serious one involving considerable physical exertion on the part of the patient, recovery cannot take place for some weeks at least, and at any moment complications may arise during which a few grammes of energy-producing food reserve may turn the scale in the patient's favour. For these reasons it is the duty of the medical attendant to see that the food-intake is adequate.

It is always risky to change the diet of a healthy infant, it is even more risky in the case of a sick one. If a baby has been thriving on any particular food up to the moment of infection it is not probable that a change will be for the better, but a change in the time of feeding may be advantageous. The giving of food to a baby or a child with whooping-cough often provokes a paroxysm; this makes the patient unwilling to feed, and frequently leads to the vomiting of that part of the meal which has already been swallowed. It is therefore better to give a feed about ten minutes after a paroxysm, at which time it will usually be comfortably retained. In the case of babies, the feed should be given after the first paroxysm occurring subsequent to the normal hour of feeding; if vomiting and loss of weight are taking place the intervals between feeds should be decreased, and the bulk of food at each feed diminished. With older children large meals must be avoided, and fluid foods such as milk, soups, &c., given between meals, the period following a paroxysm being chosen for each meal or feed.

3. *Record of Progress.*—The best record of progress in any case is given by a chart showing the number of paroxysms occurring each day. Mothers should be trained to make a note of each attack of coughing from 8 A.M. until 8 A.M. on the following day. In this way the practitioner can keep a chart such as that here reproduced, which will give him a reliable index of progress.



Specimen chart of type to be used as a guide to progress and effects of treatment in pertussis.

Specific Treatment.

Although there is strong evidence that the Bordet-Gengou bacillus is the specific cause of whooping-cough, we have as yet no specific treatment; vaccine treatment as outlined in the next section is advisable, but results are not good with sufficient uniformity to allow of such treatment being called specific.

Vaccine Treatment.

Vaccine treatment in whooping-cough, whether prophylactic or curative, is logical and harmless; it is not at present possible to say that it is invariably beneficial. I recommend it especially as an aid to the prevention of pulmonary complications, and for this reason I advocate a mixed vaccine containing the Bordet-Gengou bacillus, together with strains of various organisms commonly encountered in the pulmonary diseases of children. Such a vaccine should have a composition somewhat as follows:—

Bordet-Gengou bacillus ..	250	million.
Pneumococcus	125	,,
M. catarrhalis	50	,,
B. Friedländer	50	,,
B. septus	20	,,
Staph. aureus	250	,,
Streptococcus	20	,,
B. influenzæ	150	,,
Total	915	million per c.cm.

Of this, the dose for a child of 5 years should be 0·1 c.cm., doubling the dose every four days unless there be strong reaction; in the case of a child severely ill the dose should not exceed one-half of the above.

Symptomatic Treatment.

1. *Local.*—Good results have been claimed from intratracheal applications, but the method is too difficult for general use; unless performed by a skilled laryngologist the effects are more likely to be harmful than good. Inhalations escape from these objections, but their utility is more doubtful; creosote and benzoin are the substances most readily available, with older children they may be recommended and often appear to give relief; they should be vapourised with boiling water, the patient periodically inhaling the concentrated vapour. The practice of vapourising such substances with steam kettles or lamps should be discouraged, as it tends to lead to imperfect ventilation.

2. *Internal.*—All the common drugs used in pulmonary conditions have been tried; it cannot be said that the results have been in any way brilliant. Belladonna is often recommended; it should be given in full doses, preferably in the form of hypodermic injections of atropine sulphate, gr. 1/500, repeated four-hourly, and for a child of 2 years gradually increased to double the dose. If the signs of atropine poisoning are watched for there is no danger; smaller doses cannot be expected to have effect. A popular combination is that of belladonna with bromide, 10 minims of tincture of belladonna with 1 gr. of sodium or potassium bromide being given six-hourly to a child of 2 years. In very severe cases, where there is much loss of sleep, morphia and opium derivatives are permissible, but they must be used with caution. Antipyrin in doses of 1 gr. for every year of age, increasing to double this dose, has many adherents; it should be discontinued if complications arise.

In later stages, when there is no bronchitis, benzyl benzoate is often remarkably effective; my own practice is to give it in doses of 10 drops of a 20 per cent. alcoholic solution for a child of 2 years, adding some simple emulsion to bring the given dose up to a volume of 1 drachm. This is given every four hours in increasing doses.

In chronic cases it frequently happens that the reflex paths involved in coughing become so sensitive that a paroxysm is provoked by the most trifling causes. In such cases an attempt should be made to break the vicious circle; this is sometimes accomplished with dramatic success by means of intramuscular injections of ether; on each of three successive days, ½ to 1 c.cm. of ether is injected deep into the muscles of the gluteal region, a well-kept chart recording the paroxysms will demonstrate the value of this treatment. It should be noted that such injections are painful, which makes it inadvisable to use them except in such cases as have been indicated—i.e., when there is chronic paroxysmal coughing, without adequate exciting cause, and an effort to break a vicious circle is necessary.

Treatment of Complications.

1. *Hæmorrhages* may in rare cases be sufficiently severe to call for local treatment by plugging, &c. Small repeated hæmorrhages are in all cases an indication for active attempts to minimise the severity of paroxysms; it is such cases as these that justify the use of morphia and its derivatives.

2. *Respiratory complications* must be treated on orthodox lines; broncho-pneumonia is the chief danger to life in this infection, and it should always be remembered that the patient's chance of survival depends largely on nutritional reserve; this, as has already been said, is the great reason for careful dieting.

3. *Diarrhœa* is frequently seen in infants infected with pertussis during the summer months. Its treatment is often difficult, and the practitioner must be guided by the knowledge that in most cases the diarrhœa is merely a manifestation of the general disease.

4. *Convulsions* and other nervous complications are of grave import, but call for no treatment other than that usually employed in such conditions.

After-Treatment.

With the exception of measles, no disease is more likely to be the forerunner of tuberculosis; convalescence should therefore be carefully supervised, and whenever possible a change of environment to a mild, sunny, climate should be secured for a time. Iron and arsenic, alone or together with malt extract, are of value at this stage. Persistent infections of the naso-pharynx should be attended to, and the general resistance of the patient improved to the utmost extent by careful hygienic measures and a diet containing abundance of vitamins and lipoids.

T. Izod Bennett, M.D. Lond., M.R.C.P.,
Assistant Physician, Middlesex Hospital.

Special Articles.

GREEK COINS AND THEIR STORY: THE WEBER COLLECTION.

BY S. W. GROSE, M.A.

READERS of THE LANCET will not need to be reminded of the many-sided professional activities of the late Sir Hermann Weber, but it may surprise them to know that his hobby had for a long time been that of collecting Greek coins, of which he formed one of the most important collections, numbering some 8000 specimens, ever made in this country by a private individual. In this taste he followed another doctor of great eminence. To the medical profession the Hunterian collection means the great collection housed in the Royal College of Surgeons of England. To the numismatist and antiquary it only signifies that magnificent series of Greek, Roman, and other coins bequeathed to Glasgow University by William Hunter, "a man" as Dr. Macdonald describes him, "of singular foresight and breadth of view in every department of intellectual life," who "regarded the possession of his Cabinet as a public trust and its augmentation as a public duty." Of the 30,000 coins of this famous cabinet over 12,000 are Greek. Weber and Hunter, while each acquiring many fine examples of the mints of Magna Graecia and Sicily, had greater opportunities, and perhaps a greater predilection, for acquiring coins of the Grecian mainland and the Greek cities of Asia Minor.

This first volume[1] of the Weber catalogue contains 1795 coins, while of the Hunter cabinet some 2300, or a rather smaller proportion, belong to Magna Graecia and Sicily. There is a third collection in this country, that formed by the late J. R. McClean and given by him to the Fitzwilliam Museum, Cambridge, which contains over 3000 coins for these mints out of a total of rather over 10,000, and thus outbids in importance for that part of the ancient world both Weber and Hunter. Hunter, 140 years ago, made arrangements for his coins to be catalogued. McClean and Weber have followed that excellent example. It is unfortunate that the Weber coins have had to be dispersed; but Messrs. Spink and Son, who bought the collection, merit the warmest thanks of the numismatic and art world for the magnificent way in which they have carried out the stipulation that they should publish a catalogue of these coins; and Mr. Forrer is to be congratulated on the accomplished manner in which he has performed his labour of love in making this material accessible. It is also a great pleasure to be able to record that many pieces of the utmost rarity and of supreme historical and artistic importance have been acquired for the British Museum by the aid of a special grant from the Treasury of £10,000.

According to Greek tradition the Lydians were the first people to coin money, probably in the eighth century B.C. The invention quickly passed across the Ægean Sea to the Grecian mainland (*c.* 650 B.C.), and on to the rich Achaean colonies of southern Italy and to the cities of the princes of Sicily. The *floruit* of the art in Magna Graecia is *c.* 550–300 B.C.—some bronze issues go on beyond this date—with a period of finest workmanship *c.* 440–350 B.C. Mr. Forrer says in his introduction that he hesitated as to whether he should follow the traditional method of describing the coins according to geographical divisions or adopt the chronological method of classification advocated by Prof. Percy Gardner in his brilliant work, "A History of Ancient Coinage." We imagine that few numismatists will share Mr. Forrer's regrets that he could not see his way to adopt the chronological method. The first duty of a cataloguer is to make his material accessible, and this can be most readily done by describing the coins which belong to the same mint all together. To break up the mint sequences for a chronological arrangement can only result in chaos in a catalogue of a large collection, and is not worth attempting in a small one. Prof. Gardner has suggested lines of investigation which, he may be sure, others will not leave unexplored. But the method is for the teacher and the working out of the details for the researcher; for both of them the compiler of a catalogue has to supply the raw material, and it must always be his first care to supply that material in the most accessible form.

As to the form of the printed page, Mr. Forrer, trained by his long experience of sale catalogues, sees no reason to break away from the arrangement whereby the description of the obverse side of the coin is printed right across the page, followed by the reverse. For large collections where there may be long runs of similar coins, I believe that the arrangement of obverse and reverse in parallel columns is preferable. I should also prefer to break the pages by printing the monetary denomination in bold type before each group instead of in the same type after each coin, as Mr. Forrer has done. He is very generous, too, with his references. Six, seven, eight (1269 and 1349), even nine references (1270) may be given for a single coin, and each reference is given a fresh line. Mr. Forrer is probably justified in thinking it unnecessary to give the relative positions of the obverse and reverse dies for this part of the Greek world. It may here be mentioned that Mr. Forrer has been very well served by his printers, and the set-up of his page is most attractive.

In this volume the following may be noted as lending especial distinction to the collection.

Nos. 309, 310, early didrachms of Cumae with the head of Athene, No. 511, the earliest stater of Tarentum, with Taras incuse on the reverse, and 512, the famous stater showing Apollo Hyakinthios, one of seven known specimens, and now in M. Vlasto's collection; No. 548, a splendid gold stater of Tarentum with the types of Hera and the Dioscuri, both sides unusually well struck up with all the details preserved; this specimen is finer than that which came to the McClean collection from the Earl of Ashburnham's sale; Nos. 880–881 staters of Thurium, the first by the artist, Molossos; No. 1025, a beautiful example of the Croton stater with the seated Herakles. There are some choice coins of Metapontum and Heraclea.

In the Sicilian series I note No. 1247, a fine tetradrachm of Camarina, by the artist Exakestidas. Nos. 1268, 1269 are two superb tetradrachms of Catana by Herakleidas, particularly 1268, with the youthful head of the river-god Amenanos on a very widely spread flan; 1270, also of Catana, is by Euainetos, the head of Apollo of exceptional style. Fine coins of Gela are No. 1325 with the standing figure of Sosipolis crowning the man-headed bull Gelas, and 1330 with the head of the young river-god. Many will regard either this coin or the unique tetradrachm of Segesta (showing a slow moving quadriga in place of the usual female head) as the most desirable piece in this section of the collection. The latter coin has now passed to Mr. A. H. Lloyd. No. 1349 is the famous tetradrachm of Himera with Pelops driving the Olympian chariot on the reverse.

No. 1452 is a *tetradrachm* of Motya and No. 1453 a didrachm with the nymph's head *facing*. There are 14 tetradrachms of the period of signed artists' signatures at Syracuse, including Kimon's facing head of Arethusa, tenderest and sweetest of female heads on Greek coins, the type which immediately enjoyed a wide success and was copied in far distant parts of the Greek world. There are also three silver dekadrachms and good examples of the Syracusan gold and electrum issues. Unique, but of less interest, are two varieties of Agrigentum, Nos. 1191 and 1197.

I add the following notes on points of detail.

No. 141, the quincussis of an issue of *aes signatum*, one of six known specimens. The figures given seem to suggest that the "small fragment" which has been added weighed 635 g. Is the fragment the same as that sold with the main piece at the Tighe sale, and there recorded as a fragment of another ingot and as weighing 122 g.?

No. 198 Ariminum. Should the warrior be armed with a sword (Carelli, B. M. Cat., &c.) or with a spear, as Mr. Forrer says? My own impression is that on these coins he has a short sword and a spear, the latter being the sheath of Carelli, Pl. xxiv., 1.

---

[1] The Weber Collection. Vol. I. Greek Coins—Italy, Sicily, &c. By L. Forrer. London: Spink and Son. 1922. Pp. xvi. + 377, with portfolio of 69 plates. £3 3*s*.

No. 314. From the spacing of the letters I should judge that ↓ is a form for Y and not a plant or a harpoon as suggested by Imhoof and Sambon. McClean No. 219 has the form shaped Ψ in the writing of the ethnic usually given as AV\ IΔV.

No. 321. To judge from the style of the obverse I should wish to assign this anepigraphic coin to Nola rather than to Neapolis.

No. 332. Why not print the monogram as in other cases? The proposed resolutions do not take into account the small Λ at the foot of the first upright which is visible on the plate and on other specimens.

Nos. 365, 367, &c. "Hemilitra" in several places where "hemilitron" is intended (hemilitron used later in the book).

No. 502. Another example of a countermarked quadrans of Graxa, to be added to the seven examples of this coin, which I was able to find when dealing with the coins of this mint in Num. Chron. 1916, p. 203 seq. The weight of this specimen helps to confirm the views there expressed.

No. 503 and pass., "cockle-shell." Generations of numismatists have insisted on calling this shell by a wrong name. It is really the scallop—pecten, as Mr. Forrer adds in brackets to Nos. 649–50.

No. 720. The suggestion that this coin may belong to Caulonia is attractive.

No. 909. The obverse type reproduced on the plate is certainly of a coin of Orra. In fact, it is the coin figured on Pl. 23, No. 507.

No. 1009. The letters, I believe, are PA and not DA.

No. 1012. Π occurs with the radiating lines on the reverse of a McClean coin of Croton, combined with an obverse bearing a cantharus for symbol.

No. 1196. Compare with this coin of Agrigentum signed MΥP one of quite similar style with the fly for symbol on the obverse, which will be found in the McClean collection (No. 2042).

No. 1451, formerly attributed to Segesta, but assigned by Mr. Forrer to Motya, suggests the probability of a close connexion between the two mints. For while the ivy-leaf behind the female head on this coin occurs on coins certainly of Motya (e.g., McClean 2460)—the head itself is closer in style to an undoubted coin of Segesta (McClean 2552), where it is combined with the obverse type of this Weber coin, a hound standing on a stag's head and above it a small head, τ. This symbol also occurs on coins of Segesta with the ordinary type of prowling hound.

No. 1639. Is the reading given by Mr. Forrer as [IEΥ]ΣΛΕΥΘΕΡΙ[ΟΣ] to be accepted as a die-sinker's blunder or has E dropped out between Σ and Λ?

Misprints. I have noticed very few. On p. 46, last line, "oter" for "other"; in No. 917, rev., delete the comma after "above"; in No. 1270, "vreath" for "wreath." There is a small error in spacing in the first line of No. 356.

It appears that Weber's interest in Greek and Roman coins was "first roused by types referring to the healing art." Not many such types are to be found in Magna Graecia, the nearest approach perhaps being the coin of Himera, with the nymph at the altar and a Seilenos washing himself in the warm springs, while ceremonies of purification from pestilence are depicted elsewhere, notably on coins of Selinus. For the greatest rarities and treasures of supreme artistic value we must wait for the succeeding volumes.

Christ's College, Cambridge.

DENTAL CARIES IN RELATION TO THE STRUCTURE OF THE TEETH.

A PRELIMINARY report[1] of the special committee which is investigating the causes of dental disease has just been issued and deals with the structure of the teeth in relation to dental caries. The name of Mr. Howard Mummery as author is a guarantee of the accuracy of the histological work on which this report is based. The illustrations are beyond all praise and show that in the difficult field of dental histology this country has nothing to learn from any other. The committee has wisely decided to issue reports on various aspects of the investigation as they are completed. This interim report does not, however, represent the committee's final word even on the subjects discussed. The significance of this subject of the structure of teeth in relation to dental caries is twofold. There is, first, the question as to how far variations in the density of calcification of the teeth may predispose to dental caries; secondly, the question arises whether the enamel is to be regarded as an inert substance which, once formed, is incapable of further change, or whether it contains organic matter and may be within the pale of nutrition and possibly capable of reacting to injury like other tissues. There is a general agreement that the stagnation of carbohydrate substances, by causing the formation of acid, is the actual cause of caries; there is also agreement that gross defects of the enamel such as occur in hypoplastic teeth, by favouring the retention of starchy food, predispose to caries. On the other hand, there is considerable divergence of opinion as to the importance of structure in accounting for the widespread incidence of caries. Sim Wallace allows but little importance to this factor and points to the undeniable fact that hypoplastic teeth, though favouring the initial onset of caries, yet, because of their poorly calcified structure, often lead to a natural arrest of the process. Mrs. May Mellanby, as the results of experiments on animals, concludes that defective calcification is due to deficiencies of diet and regards it as a factor of considerable importance. In a recent paper[2] she has shown that many deciduous teeth which appear perfect to the naked eye, on microscopical examination frequently reveal defective formation of enamel and dentine. Over 80 per cent. of deciduous teeth examined showed imperfect calcification, and of these the great majority were carious. It would be unwise to stress too much the significance of this research until it has received further confirmation, but it would suggest that we must widen our definition of hypoplasia to include defects of calcification only visible under the microscope. This conception would undoubtedly extend the rôle of defective structure as a factor in dental caries, for whereas macroscopic hypoplasia is only found in the minority of children, the microscopic hypoplasia described by Mrs. Mellanby is present in a large proportion of deciduous teeth. A reflection suggests itself that on this assumption, liability to dental caries may be as much a matter of the general health during the period when the teeth are being calcified as of the dietetic conditions which exist after the eruption of the teeth. The deciduous teeth commence to calcify before birth; thus the prevention of dental disease, so far as it depends on the defective structure of the teeth, may be said to come within the scope of antenatal hygiene.

Does the Enamel Contain Organic Tissue?

The second problem as to whether enamel is an entirely inorganic substance and therefore a passive factor in dental caries, or whether it contains organic tissue and may thus be within the pale of nutrition is a much more speculative matter. Mr. Mummery subjects the available evidence to close scrutiny and adds some further evidence of a suggestive nature. C. Tomes held that enamel is entirely inorganic. If this be so, then the view of H. P. Pickerill that enamel undergoes hardening after eruption cannot be correct. Equally, the suggestion of F. W. Broderick, that in periods of calcium deficiency lime salts may be withdrawn from the enamel must fall to the ground, for both hypotheses postulate the presence of organic matter in enamel. On the chemical side the analyses of C. Lovatt Evans show a small though definite amount of organic material in enamel. On the histological side Mr. Mummery brings strong evidence to show that enamel contains spaces which are penetrable by stains. It would seem reasonable to assume that these spaces are filled with protoplasm during life, though the actual proof of this may be a difficult matter. But although chemical and histological evidence strongly suggests, and, indeed, even proves, the presence of organic matter in enamel, this is not tantamount to saying that such changes as those suggested by Pickerill and Broderick actually take place. All it does is to make them at least a tenable proposition by showing that the necessary conditions exist in enamel. The proof is still to come. To the hygienist anxious for some practical method of preventing dental disease, these speculations may seem academic, and, indeed, even harmful in that they may tend to diminish the importance of carbohydrate stagnation as the all-sufficient explanation of dental caries, and with it the simple and undoubtedly valuable prophylactic measures which are based on that theory. With this view we cannot agree. With increasing research the problem of the ætiology of dental caries becomes correspondingly complicated. It would be doing an ill service to scientific dentistry to make the problem a simple one by arbitrarily excluding factors which are admittedly speculative at present. We are glad that the committee, as shown by the report, intends to take a wide view of the subject and to examine carefully every factor which may possibly throw light on the causation of dental caries.

Arrested Caries.

A section of this report is devoted to the subject of "arrested caries," a condition of great practical importance. It has long been known that in certain circumstances the process of caries may be arrested and the tooth become even harder than normal. It occurs commonly in the deciduous teeth, but may also be present in the permanent teeth, especially in hypoplastic molars. The caries, instead of spreading down the dentinal tubules toward the pulp, spreads laterally and causes a large area of the enamel to flake off. This leaves a broad, flat surface which does not favour food retention; at the same time the pulp reacts to an injury not intense enough to kill it, and causes a hypercalcification of the dentine. Such a tooth, though discoloured and partly eroded, may last for many years in a healthy condition. Though we know the general factors which bring about this protective reaction, we do not yet know them in such detail as to be able to induce the condition with certainty in any given case.

Dental Therapeutics.

Mr. Mummery discusses the use of silver nitrate in arresting caries. This drug has long had a popular repute and is undoubtedly useful. Is it possible to use it to better advantage? Is the reduced silver-nitrate method, introduced by P. Howe and widely used in America, better than the solid silver nitrate as generally employed in this country? Further investigation of the question is still needed, for a combination of clinical and laboratory methods might solve the difficulty.[3] A knowledge of all the factors necessary to bring about this natural arrest would increase the scope of dental therapeutics enormously. School dentistry holds an assured place to-day as one of the ways of safeguarding the public health. At present arrested caries occurs sporadically, and in the minority of cases. Could we possess in full detail the knowledge necessary to control this beneficent reaction and so induce its occurrence on a large scale, school dentistry would gain immeasurably in efficiency. It is far too early yet to predict the outcome of the Committee's deliberations, or even to forecast the scope of their investigation, but we may confidently expect that this will leave no aspect of the problem unexplored. Especially do we hope that the clinical aspects of dental caries will receive careful investigation, for we believe the study of these to be essential to a full solution of the problem.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Preparations for the Thirty-fifth Congress of Internal Medicine.

ON April 9th the Thirty-fifth Congress of German-speaking Physicians (Internal Medicine) will be opened in Vienna and will last for four days. Prof. Karl Wenckebach has been chosen President, and will be responsible for the arrangements. Two chief subjects to be discussed are (1) encephalitis lethargica, and (2) arterial hypertension. Two eminent investigators have been asked to present the first subject—Prof. K. Economo (Vienna) and Prof. Nonne (Hamburg); whilst the other will be introduced by Prof. A. Durig (Vienna) and Prof. F. Volhard (Halle). During the Congress it is intended to show a large series of patients with disturbances of the endocrine glands collected from the Vienna clinics, and to hold a discussion on this subject. The medical staff of the University of Vienna have addressed an open letter, published in the leading German medical journals, to medical men working in German clinics, urging them to attend in large numbers, as the younger Viennese practitioners desire to become better acquainted with the ideas of their German colleagues.

The Austrian Cancer Society: A Competition.

A prize of 2,000,000 kronen—a fairly large sum for this country, but only equivalent to about £6 10*s.*—is offered by the Austrian Society for Investigating and Combating Cancer, for the best paper published up to the end of 1923, which effectively promotes the progress of the campaign against this disease. Austrians are especially invited to compete, as it is not expected that foreigners would be attracted by such a comparatively trifling prize, but, of course, all investigators are welcome, as long as their papers are written in German or translated into that language. The paper need not emanate from a recognised laboratory or clinic; a private practitioner or any medical man may compete. A large number of entries from among the younger Austrian men is expected.

Report of the Austrian Pasteur Institute.

Dr. Schweinburg, of the Vienna Pasteur Institute, has prepared, in time for the centenary of Pasteur, a report which bears out the excellent results obtained by the method inaugurated by that famous scientist. The report compares the results of treatment in inoculated and uninoculated persons since 1880. In the first decade dealt with in the paper 3024 people were bitten by animals in Old Austria, of whom 822, or nearly 27 per cent., succumbed to the effects. Statistics from other countries, however, differ greatly in the mortality percentage; some show 19 or 11 per cent., and various German papers give so low a percentage as 7, or even 2. These statistics, however, are not convincing, for not all persons bitten by animals report to the health authorities; the incidence of rabies amongst the biting animals not being too frequent, the population very often attaches no importance to slight injuries, although the latter may prove fatal later on, and statistics are, therefore, often fallacious. But when in 1913 rabies was imported into the district of Vienna strict measures were at once adopted. Coöperation between an up-to-date Board of Health, practitioners alive to the importance of exact reports, and the well-equipped and well-managed Pasteur Institute of Vienna facilitated widespread research. All persons bitten within the boundaries of Vienna were, with hardly an exception, brought to the Pasteur Institute or were reported to it by the police, who had strict orders in that respect. All these persons who had been bitten, even if untreated, were kept under police observation for at least a year, and a regular report was made to the Institute. All persons suspected of rabies, as well as all post mortems where there was any suspicion of the disease, were reported on. Thus there was no likelihood of a case escaping the knowledge of the Pasteur Institute. As the epizoötic lasted for six and a half years (it was not declared extinct until the second half of 1919) there was a good opportunity for observation. Altogether 977 persons were reported to have been bitten by diseased animals, chiefly dogs. Of these patients eight (0·80 per cent.) died, although they were treated within eight days after receiving the injury, which was always severe. The same number of deaths (eight) occurred in that same period of six and a half years amongst persons who had not received antirabic treatment. The inference, therefore, is that at least 90 per cent. of all persons bitten were reported to the Institute, with a mortality of 0·80 per cent., and that the remaining small numbers of untreated persons had a very high mortality. Otherwise the number of eight deaths is inexplicable. The injuries inflicted by dogs proved to be most dangerous, nearly all the fatal cases belonging to this group. Out of 610 cases bitten by dogs, six died, and two deaths were due to bites by horses. The other biting animals were cats, a monkey, a fox, sheep, goats, and pigs. From his observations Dr. Schweinburg concludes that Pasteur's treatment is clearly a most effective means of counteracting the dangers arising from the bites of animals, and that immediate treatment is almost the only means of saving the victim's life.

[3] For an interesting discussion of this subject see Wirkung von Silbernitrat bei der Behandlung der Milchzahncaries, E. Winzenried, Schweizerische Monatsschrift für Zahnheilkunde, November, 1922.

Death of Prof. Ferdinand Alt.

Dr. Ferdinand Alt, professor of otology at the University of Vienna, died recently at the age of 53 years after a prolonged illness. He was one of the enthusiastic group of followers, and a favourite pupil, of Politzer. He himself paid much attention to anatomical research and to the pathology of the inner ear; disturbances of musical hearing were the especial subject of his investigations. His work resulted in considerable progress in the surgery of the labyrinth. Of late years his chief interest lay in the instruction of students in otological surgery, and his classes were much frequented by foreigners.

Unrest Amongst Midwives.

When in 1919 a new Midwives Act was under consideration in the National Assembly, coöperation of those concerned—viz., midwives, boards of health, and local administrative boards—resulted in a Bill being drafted, which ensured to this important class of public health workers a certain degree of provision for old age and sickness, and a moderate income out of public funds. But the draft was not destined to become law, and a large number of midwives recently assembled from all parts of the country in Vienna and marched in procession to the Assembly, demanding a definite settlement of their grievances, failing which they threatened to institute a strike. This would entail serious inconvenience to the public, for medical men are thinly scattered in many parts of the Republic. Rural districts are very badly off in this respect, as naturally even small towns offer a much larger scope for medical practice than regions populated only by peasants. Representatives of various corporations supported the demonstration, and a deputation to the Government obtained a solemn pledge that the Bill drafted in 1919 will be brought before the National Assembly as soon as possible, the necessary changes due to the monetary situation of the moment being taken into consideration.

Ignorance and Infant Mortality.

The appalling part played by ignorance and illiteracy in the causation of illness and death is well illustrated in a report prepared for the Austrian Eugenic Society, and dealing with the reasons for infant mortality in certain of the wealthier districts of Austria. This report shows that where schools are normally attended (in industrial districts) the mortality is rarely above 12 per cent. in the first year of life. In rural districts, however, where ancient customs and views of rearing babies are still in vogue, and where illiteracy is almost universal, the figures go up to 17, 21, and 27 per cent., and in some hamlets even 90 per cent. of all babies born die before they complete their first year. Competent investigators have reported that on the Tyrolese and Upper Austrian frontier, in a very rich sub-Alpine district, when the majority of the Austrian population were semi-starved by war, meat, milk, butter, and bread were obtainable in abundance. The mountain population abhors the breast-feeding of babies, which is regarded as indecent, in that animals feed their young in that way. According to their traditions, the new-born baby is fed on a thick soup of flour and sugared water from the first day, and little milk is given. The peasants refuse to entertain the ideas of sterilisation of milk or of breast-feeding. Bottle-feeding is, however, practised, but to excess, as fat children are a source of pride. Qualified nurses are unknown, although the peasants are frequently not only well-to-do but even wealthy. The dangers of tuberculosis are not even believed if explained by a casual medical visitor. The simplest prophylactic measures—e.g., disinfection in scarlet fever or diphtheria—are unknown; the local method of "disinfection," indeed, consists chiefly of closing windows and abstaining from washing when ill. Alcoholic beverages are freely used, and treatment of the frequent ailments of babies, such as summer diarrhœa or acute gastric conditions, is in the hands of old women as ignorant as the mothers themselves.

CZECHO-SLOVAKIA.

(FROM OUR OWN CORRESPONDENT.)

Ministry of Health: 1923 Budget.

IN 1921 the Ministry of Health and Physical Education had at its disposal about 88 million crowns, and 149 millions in 1922; and 207 millions are budgeted for in 1923. It is interesting to compare the proportionate allotment of expenses in the various budgets of the new Republic. At first central administration and the fight against epidemic diseases required most attention; succeeding budgets displayed a tendency to spend more on social diseases, the epidemics having been practically stamped out. A considerable increase is to be noted under the 1923 heading "State Institutions." Several causes contribute to this increase. First, the fact that the Government has nationalised many hospitals on account of their miserable financial situation; secondly, the establishment of a system of control laboratories all over the territory of the Republic; thirdly, the building of a central Institute of Hygiene in Prague, undertaken with the coöperation of the Rockefeller Foundation, and necessitating the appropriation of nearly 50 million crowns. The item for inland watering-places shows no great increase; State administration of many spas, which were nationalised some years ago, did not prove very satisfactory. The item relating to epidemic diseases shows no change in comparison with previous years; 5 million crowns seem to be sufficient for the protection of the country against the spread of epidemics from neighbouring States. The expenses connected with venereal diseases have risen from 12 million to 14 million crowns owing to a new law which took effect in the middle of 1922. Expenditure on child welfare has steadily increased from year to year. The child welfare centres created by the American Red Cross, and later taken over by the State, are responsible for an increase which brings this item up to 7 million crowns for 1923. Physical education is responsible for a slight increase. Expenditure on sanitation and construction of hospitals is shared between the Ministries of Health and Public Works. The State budget also contains certain provisions for public health purposes; for instance, 17 million crowns are appropriated for patients in general hospitals who are unable to pay their fees, and for whom nobody else is responsible. The sum of 31 million crowns for nationalisation of hospitals is smaller by 6 millions than the figure for the previous year. The largest increase appears in the salaries of the public health personnel, as a result of the nationalisation of the health service, which was put into effect on Jan. 1st, 1923. The nationalisation law was passed by Parliament over two years ago, but was postponed on account of the necessity for strict economy in State administration. The present Minister of Health, in spite of the opposition of the medical profession, has included the provision of a sliding scale for salaries of local health officers, which will depend, inter alia, on the amount of income from private practice. This provisory arrangement should make it possible for medical practitioners to settle as local health officers in remote country districts, where as private practitioners they have not hitherto been able to earn a living on account of the poverty of the population.

Venereal Disease.

The venereal diseases survey, carried out by the Ministry of Health in 1922, has shown that Carpathian Russia, an autonomous territory closely connected with the Czecho-Slovak Republic, is badly stricken with endemic syphilis. The disease has apparently existed in this territory for many years, being widely spread among the scattered population even in the smallest villages. The annual incidence is about 200 per 100,000 of the population, according to an experimental report made in February, 1921. This is a higher rate than that of Bohemia, where the much greater density of population and the industrial character of the work make the spread of venereal diseases more likely. It is noteworthy that in Carpathian Russia the incidence of hereditary syphilis amongst females is almost double that amongst males in the same district; this phenomenon is apparently due to the higher resistance to all diseases manifested by girls as compared with boys. In the Republic proper the ratio between the number of the three venereal diseases is very constant; approximately 31 per cent. of fresh infections are due to syphilis, 12 per cent. to chancroid, and 57 per cent. to gonorrhœa. In Carpathian Russia, however, 50 per cent. of the total of venereal infections are syphilitic—a fact which seems to indicate a source of infection other than sexual intercourse, probably infection by contact.

The Ministry of Health is planning a special campaign for the eradication of this disease, which is undoubtedly largely responsible for the poverty and slow progress of the district.

CONSULTATIONS FOR PANEL PRACTITIONERS.

THE question of consultations in insurance practice was raised by a recent deputation from the Insurance Acts Committee to the Ministry of Health, when it was urged that the insured person ought to be placed in a similar position to that of the private patient. Involving, as it does, the provision of funds to pay consultants' fees, this ideal may not be realised for some time; and, when the money is found, some control must still be exerted by the administrators. A demand which has been heard that insured persons should have free access to specialists apart from their medical advisers is due to a misconception of the proper function of consultants. The medical attendant, along with the patient and his friends, are, of course, the proper people to decide upon the necessity for further advice, the object of which is the speedy recovery of the sick person. In the case of an insured patient, the object remaining the same, there is, however, another party profoundly interested in the duration of illness—namely, the approved society of which the insured person is a member. Memo. 281 sanctioned[1] a reference to the regional medical officers by an approved society on any of their members in receipt of sickness benefit for a period of four weeks. The conference of panel committees expressed a very definite opinion "that nothing should be done to interfere with the responsibility and duty of an insurance practitioner in determining in association with his patients the necessity of a consultation for insured patients." But Memo. 281 gives the initiative to the approved society without necessarily informing either patient or doctor, and it is argued that, whenever a society desires a consultation in regard to one of its members, the suggestion should first of all be made to the patient, who should be left to mention it to his doctor. The safeguard against the misuse of this provision is the actual procedure by which the regional staff of the Ministry of Health deal with the references. In every case the doctor is asked for a report, on receipt of which the regional medical officer decides whether a consultation would or would not serve any useful purpose. It appears that a large proportion of references for consultation are nipped in the bud at this stage.

Clearly, approved societies are not in a very good position to choose the appropriate cases for consultation, and in general the insurance practitioner can be trusted to decide upon this necessity. He is indeed only too glad to secure expert advice. At present he has mainly to depend on the good offices of voluntary hospitals, and the need of a panel of consultants grows from day to day. The requisite control could be secured through the present regional staff, who would presumably see the patient first, except in case of urgency. Meanwhile much expert advice and treatment is provided at the hands of insurance doctors themselves in hospital, more especially in the smaller towns and rural areas where the cottage hospital is staffed by local practitioners. Major operations, as well as electrical and X ray treatment, are frequently undertaken there without fee and with only a nominal charge on the part of the hospital. The sense of grievance that these extra services must be given without extra remuneration is mitigated by the fact that the work done in the operating theatre and X ray room adds zest and interest to routine clinical work.

THE WORK OF THE LONDON PANEL COMMITTEE.

The election of representatives to a panel committee is held, as a general rule, in every second year, the next election occurring in June, 1923. The London Panel Committee, which safeguards the interests of 1500 practitioners in the London area at an administrative outlay which has averaged 0·45 penny per insured person during the last three years, while issuing a monthly gazette, has received many suggestions for consideration whereby the medical benefit regulations may be so amended as to meet the desires of panel practitioners in the London area. In a recent issue of its *Gazette* the London Panel Committee reminds practitioners that many of the provisions contained in the regulations are unalterable without amendment of the Acts themselves. The inclusion of the word "preventive" in the title of these Acts definitely included all measures of a preventive nature and thus brought vaccination against small-pox as an obligatory service, for it cannot be contended that it is a service beyond the competence and skill of a general practitioner. In cases where a complaint has been lodged against a practitioner, the advice and assistance of the Panel Committee's solicitors are available free of charge, and the Panel Committee itself is assisted in its work by three standing subcommittees. In addition to this work, the Panel Committee appoints representatives to certain outside bodies, the expenditure on which cannot be defrayed out of the statutory income of the committee. It is not a little remarkable that busy London practitioners can be found who are willing to give their time freely to arduous administrative work. The London Panel Committee has rightly taken pride in its ability to speak for a large section of insurance practitioners. Amongst its members have been found, from the first, men of wide experience politically and professionally who have brought enthusiasm to the consideration of the future development of the insurance service. Valuable memoranda have been issued setting out schemes for the smooth working of the insurance medical service and particularly for the better administration of the Insurance Acts. We are glad to learn that the London Panel Committee is now effectively coöperating with the Insurance Acts Committee of the British Medical Association in its conferences with the Ministry of Health.

---

[1] THE LANCET, 1922, ii., 633.

THE MEDICAL SERVICE OF THE NATIONAL HEALTH INSURANCE ACTS.

A conference has been called, by the Insurance Acts Committee of the British Medical Association, of bodies interested in the medical service of the National Health Insurance Acts for Tuesday next, Jan. 30th, at 11 A.M., in the Council Chamber of the Guildhall, London. The question of the efficiency of the service now rendered will be introduced by Sir Thomas Neill, chairman of the Executive Committee of the National Conference of Industrial Approved Societies. A debate on such practical matters as surgery hours and accommodation, size of panels, and provision for emergency treatment will take place.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Capt. H. L. Penny is placed on the Ret. List with rank of Surg. Rear-Admiral.

The following appointments have been made: Surg. Lt.-Cmdrs. L. A. Moncrieff to *Birmingham* for Trooping trip; R. J. Inman and H. E. Y. White to *Britannia* for sick quarters, Dartmouth; and L. S. Goss to *Thunderer;* Surg.-Lts. R. W. Mussen to *Cyclamen*, and W. A. Jolliffe to *Calliope*.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. H. A. L. Howell retires on ret. pay on account of ill-health caused by military service, and is granted the rank of Col.

Capts. C. E. Petley and C. K. G. Dick retire, receiving a gratuity.

Capt. J. C. Burns is placed on the half-pay list on account of ill-health.

ARMY RESERVE OF OFFICERS.

Col. T. P. Jones (late R.A.M.C.), having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

Col. H. A. L. Howell (late R.A.M.C.) ceases to belong to the Res. of Off. on account of physical unfitness.

Lt. C. C. H. Chavasse (late 4th R. Warwick. R., Spec. Res.) to be Lt.

TERRITORIAL ARMY.

Lt.-Col. T. Donovan resigns his commn. and retains the rank of Lt.-Col. with permission to wear the prescribed uniform.

Lts. J. Bowen-Jones and G. Nicholson resign their commns. and retain the rank of Lt.

The undermentioned relinquish their commns.: Maj. F. R. M. Heggs; Capts. R. Hargreaves, S. A. S. Malkin, and R. S. Weir.

Capt. F. J. Nattrass relinquishes his commn. and retains the rank of Capt.

Capt. F. W. Martin (late R.A.M.C.) to be Lt., and relinquishes the rank of Capt.

Capt. H. M. Pentreath, having attained the age limit, is retired, and retains the rank of Capt.

Capt. G. N. Anderson, from Sanitary Companies, to be Capt.

General Hospitals: The undermentioned, having attained the age limit, are retired and retain their rank, except where otherwise stated: Lt.-Cols. W. Pasteur and A. H. Tubby (granted the rank of Cols.), W. G. Richardson, and H. B. Angus; Majs. (Bt. Lt.-Col.) Sir H. F. Waterhouse, (Bt. Lt.-Col.) R. A. Bolam (granted the rank of Lt.-Col.), S. H. C. Martin, J. D. Wardale, R. P. R. Lyle, J. W. Leech, W. D. Arnison, and T. M. Allison; Capts. Sir A. D. Reid (granted the rank of Lt.-Col.), (Bt. Maj.) W. C. Bosanquet (granted the rank of Maj.), E. R. Carling (granted the rank of Maj.), F. H. Humphris, T. G. A. Burns, H. R. D. Spitta, H. J. Marriage, and E. W. Hedley.

Correspondence.

"Audi alteram partem."

THE TREATMENT OF EARLY PULMONARY TUBERCULOSIS IN THE YOUNG ADULT.

To the Editor of THE LANCET.

SIR,—Those of us who are interested in tuberculosis work feel grateful to Dr. Lillingston for his able and lucid contribution in your issue of Jan. 13th. He points out with no uncertain voice that the so-called "simple life" is fraught with the greatest danger. The patient who is for the time being his own physician is not sufficiently "educated" to control his exercise and rest, with the result that in the majority of cases auto-inoculation gets the upper hand and the disease progresses. When this pet method of treatment has failed, and the case has become a nuisance to the family physician and others the patient is recommended to go to a sanatorium for a *few weeks* instead of a *few months*. Usually the case is then in the third stage, and arrest wellnigh impossible.

In regard to the so-called specific treatment generally, I am glad to read that Dr. Lillingston believes that they act chiefly by suggestion and by allowing the physician to control the movements of his patient. Dr. Prest is rather premature when he talks of colloidal calcium as a specific. If so, it should show results not only in first stage cases (and the majority of these do well on rest and fresh air treatment), but also in those where the disease is more advanced. I have now given this remedy a trial in 20 cases where sanatorium treatment (of 3 to 18 months' duration) had not produced any definite benefit. These cases were in the second or third stage of the disease, and the treatment was carried out in accordance with instructions as laid down by Dr. Prest in his original article. But it is very disappointing to have to record no material improvement either in signs or symptoms in most of these cases. There was no disappearance of tubercle bacilli in any of the patients' expectoration. The very slight improvement recorded in only three cases could easily be accounted for by the vagaries of this remarkable disease. Surely, then, it is hardly possible to call this remedy a specific in the proper sense of the word.

But there is one method of treatment first advocated by Sir Robert Philip many years ago which I think has not received the support it deserves. I mean the per-cutaneous method of tuberculin treatment by Moro's ointment. I have now used this method in certain type of cases for the last three years with very encouraging results. It is particularly indicated when a certain stage of convalescence has been reached and when the organism seems satisfied to live on friendly terms with the tubercle bacilli. Tuberculin therapy then seems to give the coup de grace to the more or less dormant and inactive bacilli, and the few remaining symptoms including the sputum disappear. The remedy is a perfectly safe one, and there is little or no danger of lighting up a quiescent focus. In certain forms of so-called surgical tuberculosis, such as glands and superficial sinuses, the results are indeed striking.

In regard to the treatment of hæmoptysis (large or small) I entirely agree with Dr. Lillingston when he condemns the use of morphia generally. For several years now I have been using calcium chloride intravenously (or intramuscularly in weaker solutions) and it is undoubtedly the remedy par excellence. Used with due care it is not such a dangerous drug as some physicians seem to think.

I am, Sir, yours faithfully,
FELIX SAVY.

Grampian Sanatorium, Kingussie, Jan. 20th, 1923.

To the Editor of THE LANCET.

SIR,—I can hardly think that Dr. Lillingston is really familiar with modern technique in the therapeutic immunisation or chemotherapy of either pulmonary or other forms of tuberculosis. If he were it seems to me very unlikely that he could state that immunisation acted merely by a process of suggestion. He must have used very non-specific antigens or very impotent intravital germicides. It seems perhaps invidious for me to suggest that he might read two small books in English instead of voluminous tomes in French or German and find there that the subject had already been disentangled.

I am, Sir, yours faithfully,
W. M. Crofton.
University College, Dublin, Jan. 18th, 1923.

To the Editor of The Lancet.

Sir,—The correspondence arising out of Dr. Claude Lillingston's paper in your issue of Jan. 13th, while both interesting and suggestive, appears to me to show rather loose thinking as to some of the essential factors underlying the treatment by rest and graduated exercise respectively. It seems to be assumed that graduated exercise only acts by inducing auto-inoculations and that the absence of temperature after such exercise depends on "tolerance" to auto-tuberculin. May I suggest that the case that does best on graduated exercise is one in which the lesions are so well shut off by cellular reaction and proliferation that the auto-inoculations are minimal. Such a case is usually one of reinfection in a relatively resistant subject, and owing to his power of sharp reaction, is easily diagnosed and passes for an "early case." What such a patient requires is re-education in the respiratory function which has been partially lost during the illness that accompanied his reinfection. He can stand this re-education *because his auto-inoculations are minimal*; and his gain in weight, condition, and general health is perhaps as much the result of increased metabolism and good food as of the small auto-inoculations that may occur. It is a mistake to suppose that such a man is "tolerant." An injection of tuberculin is usually sufficient to prove that patients of this type are really "intolerant" or "allergic," a fact to which they probably owe their power of shutting in their tuberculous foci.

Nobody who has seen the results of graduated exercise in sanatoria run on "Marcus Paterson" lines can doubt the value of this form of treatment in suitable cases when carefully controlled by temperature records. But for cases of a less "balanced" type, where the lesions are still in an exudative stage, and auto-inoculations are easily induced and considerable in amount, treatment by rest is imperative and even graduated exercise may well be dangerous. There is a danger that the advocates of "rest" on the one hand and of "exercise" on the other may come to be regarded as belonging to opposite camps. Surely it is for the skilled physician to make use of both "rest" and "exercise" as his instruments for the control of auto-inoculations and the graduation of metabolism to meet the needs of the individual case.

I am, Sir, yours faithfully,
S. L. Cummins.

SMALL-POX AND AMAAS IN SOUTH AFRICA.

To the Editor of The Lancet.

Sir,—A reference by Dr. J. A. Mitchell, Chief Health Officer, Union of South Africa, in The Lancet of Oct. 14th, 1922, to an outbreak of small-pox at Kimberley in 1882, induces me to give a short record of experiences in that epidemic. When small-pox began, the mine owners feared that if the disease was mentioned the farmers would take fright and not bring in fuel. The term "chicken-pox" was adopted and Dr. Jameson clung to this diagnosis for a time and then shifted to pemphigus, although a lady in Cape Town was informed it was small-pox, but it would not do to frighten people, &c. Meanwhile the epidemic was devastating the kafirs, who were dying in scores, as well as unvaccinated whites who believed Dr. Jameson's diagnosis of chicken-pox or pemphigus. I wrote to the press and pointed out the serious position—that the disease was virulent small-pox, but failed in my efforts to convince the public. A deputation of doctors from Cape Town arrived and examined the cases, but left without establishing a definite diagnosis.

I saw that some more decisive and impressive step must at once be taken. I despatched pieces of skin from a white man unvaccinated who had died from the disease (one to *The Lancet* and one to the *British Medical Journal*), and both authorities stated it was virulent small-pox and warned the public about instant vaccination. I took the photo of a baby who was born covered all over with small-pox, and forwarded it to the home medical papers. One man remarked of this that it ought to be reprinted in every book dealing with small-pox.

The verdicts of *The Lancet* and *British Medical Journal* impressed the members of the Kimberley town council, who requested me to vaccinate all and sundry in Kimberley. At the time I had no lymph but remembered a baby who had been vaccinated. From the baby I got three or four tubes of lymph—the vesicles were at the seventh day. I vaccinated four young kafir boys who were closely examined and seemed as pure in blood as young spring bucks on the veldt—a relay of these boys was always kept up. Well, in brief, I vaccinated 10,000 kafirs in six weeks, when the epidemic was stamped out. On one day a hospital would become empty and not another case would arrive. Three scrutineers were appointed to watch the vaccination. No manager complained I hurt his boys; there were no septic arms and no deaths. Dr. Jameson, during the epidemic, was prosecuted for admitting a contagious disease into a general hospital. A court case resulted, and the usual bickerings took place. A witness was put into the box who swore I treated his wife for cancer when, in fact, she was pregnant. The magistrate, seeing me in the court, stated that as this was sprung upon me unawares I could reply. I stated it was absolutely false. I looked up the case afterwards, and found I was treating her for pregnancy with Hewlett's bismuth and pepsin mixture.

Towards the close of the vaccination I asked Mr. Denis Doyle, the sanitary inspector, to bring in all and sundry still unvaccinated, and he succeeded one morning in producing 1000 natives composed of every type of aboriginal in South Africa. These were vaccinated on a Sunday morning, and with that the epidemic closed.—I am, Sir, yours faithfully,

Wm. Robertson.
Mossel Bay, South Africa, Nov. 14th, 1922.

SULFARSENOL IN THE TREATMENT OF SYPHILIS.

To the Editor of The Lancet.

Sir,—Dr. M. W. Browdy in his letter to The Lancet of Jan. 20th, commenting on my article of Jan. 13th, stated that those cases of syphilis that react badly to arsenobenzol compounds can be still treated by these compounds if certain precautionary measures are adopted, such as avoiding exposure to cold, allowing a certain amount of food before injection, and by giving contramine intramuscularly. No one can dispute that these precautions are of great help, but several of my patients have taken all these safeguards before an injection, besides glucose given by the mouth or intravenously, and also injections of adrenalin, and still had severe after-effects. When it was found that these cases had no after-effects following sulfarsenol, we had to conclude that this was the best drug to give them. In the complications of gonorrhœa I have found that neither intramine nor contramine has anything like such a dramatic and permanent effect as sulfarsenol. As regards contramine being safer, a 0·12 dose of sulfarsenol contains about ⅓ gr. of arsenic, and can be safely given to a child.

I am, Sir, yours faithfully,
Harley-st., W., Jan. 22nd, 1923. F. Carminow Doble.

RECURRENT PYREXIA IN PHTHISIS.

To the Editor of THE LANCET.

SIR,—Dr. R. C. Wingfield, in his article on Secondary Infections Complicating Pulmonary Tuberculosis in your issue of Jan. 13th, recognises a clinical type of case where sudden attacks of pyrexia are a feature not due to tuberculous auto-inoculation coinciding with increased exercise. I have seen these cases and I agree they are unassociated with exercise. It seemed to me the pyrexia might be assigned to a sudden increase in toxic absorption through improper drainage of some cavity, probably, in attempting to heal, the mouth of a cavity may become partially occluded, in which case the free exit of sputum would be hindered. As soon as the tension in the cavity was sufficient this condition of affairs would be relieved, there would be an increase in sputum, and the temperature would fall. I knew a case with a large cavity where a marked decrease in expectoration would invariably precede one of these attacks.

I am, Sir, yours faithfully,
C. B. WILSON, M.R.C.S. Eng.

San Remo, Italy, Jan. 15th, 1923.

DANGEROUS DRUGS ACT, 1920.

To the Editor of THE LANCET.

SIR,—While reserving any detailed criticism of the Act for a paper I am to shortly read before the Medico-Legal Society, the following brief comments may be of service to my professional brethren.

1. Regulation 6, Section VII., lays down inter alia that " a prescription for any of the drugs shall only be dispensed . . . . if the person dispensing the prescription is *acquainted* with the signature of the medical practitioner, &c., by whom the prescription purports to be given, or is *acquainted* with the *person* for whose use the prescription is given and has no reason to suppose that the prescription is not genuine." (Words omitted are unnecessary to my point ; italics mine). Now it is not inconceivable that both doctor and patient may be unknown to the chemist, hence the advisability of carrying a sufficient supply of these emergency drugs when travelling beyond one's own district, and since no doctor may " prescribe " for himself the same precaution applies when he takes his family on holiday.

2. Although there is no obligation placed upon the non-dispensing doctor to keep records, yet since the script is retained by the chemist the patient on a subsequent visit will not be in possession of the prescription, and hence the practical need of preserving a copy as an aid to memory.

3. The dispensing doctor. Regulation 9, which enacts the keeping of records beyond the day book, will be recognised by anyone acquainted with the distractions incidental to the life of a G.P. to be an impossible burden and, as I hope to show in my paper, is doomed to failure from mere vis inertiæ.

As I have found much misunderstanding abroad and have been sought in advice on several occasions, may I add that (*a*) any doctor conforming to the regulations as to prescribing may order any drug and in any strength he desires ; (*b*) that he is unfettered in his personal use of the drugs as local anæsthetics ; and (*c*) that he can avoid all trouble in obtaining supplies by ordering from a wholesale house.

Lastly, since the present regulations are only a beginning, and envisaging the more drastic legislation which prevails in the United States of America, and which supplies a stimulus to " reformers " on this side, would it not be well that a watching committee be set up to guard the interests and conveniences of the profession and more especially of the already overburdened general practitioner? In these cases not only is prevention better but easier to achieve than cure. The possibility and hope of being helpful is my apology, Sir, for this incursion upon your space.

I am, Sir, yours faithfully,
H. A. BURRIDGE.

King's College Hospital, S.E., Jan. 20th, 1923.

CŒLIAC DISEASE.

To the Editor of THE LANCET.

SIR,—I have followed with interest the contributions of Dr. Reginald Miller and his collaborators to your columns on the subject of cœliac disease. My interest in the subject has been further stimulated by the study of a young adult patient (under the care of Dr. A. F. Hurst) presenting most of the classical features of the disease, and it has occurred to me that a description of the case might possibly help to elucidate the hitherto obscure problem of its pathogenesis. In his paper on a Fatal Case of Cœliac Infantilism,[1] Dr. Miller concludes " that cœliac disease is independent of organic changes " in pancreas, liver, or intestine, and he bases his opinion on an analysis of the only four recorded autopsies. Curiously, however, no specific mention is made in any of the post-mortem reports of the state of the lacteals and the thoracic duct, notwithstanding that these constitute an important part of the fat-absorbing apparatus. In the case described hereunder the symptoms resulted from obstruction to the lacteals, and I believe that it is in the lacteals or thoracic duct that the lesion of cœliac disease must be sought before it can be finally decided that the disease occurs independently of any organic change. It must be admitted that the lymphatic system of the bowel and mesentery very rarely receives close attention during the routine performance of autopsies, and when the viscera have been removed in the customary way by a post-mortem room attendant a satisfactory report on the system becomes almost impossible.

A young woman, aged 23, gave a history of attacks of diarrhœa since she was a baby. In recent years they had become more continuous and sometimes she passed as many as six or more stools in a day. From the age of 15, whenever she got over-tired, during the menstrual periods, and particularly when the diarrhœa was bad, she had attacks of tetany. She had not lost weight. When she came under observation it was discovered that the " diarrhœa " consisted in the passage of enormously bulky, semi-fluid stools of a porridgy consistency, greasy and rancid, and containing an obvious excess of intimately mixed fatty material. The patient was of small stature, but well proportioned and looked younger than her years. The abdomen was full, especially in its lower half, and felt unusually firm and doughy. On account of persistent tenderness in the right iliac fossa a laparotomy was performed and an actively inflamed appendix was removed. At the operation the lacteals were seen to be in a remarkable state of dilatation, standing out as tortuous, white cords ; the mesenteric glands were enlarged and many of them were caseous. There was, however, no tuberculous peritonitis, and the appearance of the bowel did not suggest the presence of any ulceration. In brief, the case was one of tabes mesenterica with very extensive obstruction to the lacteals. The symptoms which had developed as the result of this obstruction and the character of the stools were closely similar to those described in cœliac disease, and tetany—a complication of cœliac disease—was also present. After the operation the patient was treated for a year as a case of tuberculosis. On withdrawing fats from her diet the stools were reduced to one or two per diem and became normal in consistency and colour, but remained abnormally bulky, conforming closely with the description of the stools in Dr. Miller's cases of non-diarrhœic cœliac disease (THE LANCET, 1923, i., 72). There was no recurrence of tetany, and the patient is now leading a normal life, though it is necessary for her carefully to restrict her fat-intake. The history suggested that the trouble had been present for many years, possibly even from infancy, without the patient manifesting any other signs of tuberculous disease.

When two diseases produce almost identical symptoms it is difficult to avoid the conclusion that they possess some common pathological factor, and on the analogy of cases of this type one feels tempted to prophesy that in the next fatal case of cœliac disease some macroscopic or microscopic lesion of the lacteal system will be found. The lesion need not necessarily be tuberculous, and, in fact, the complete absence of evidences of tuberculosis is claimed as a characteristic of cœliac disease. There is, however, the very frequent incidence of fever to suggest an infective origin, and one cannot refrain from remarking on the comparatively good tendency to recovery with healing in tabes mesenterica and on the closely similar abdominal signs in the two diseases. It must be a comparatively rare occurrence for tabes mesenterica to obstruct the lymphatics so completely as to give rise to steatorrhœa of a copious kind. In 1855 Gull wrote a paper in the Guy's Hospital Reports on Fatty Stools from Disease of the Mesenteric Glands. In this paper he states that "the normal absorption of fatty matters is prevented from two causes: either from a defect in the digestive or emulsifying processes, or from disease of the absorbent system," and he proceeds to describe the differences in the appearance of the stools according to their respective pathologies. Of the stools due to defective absorption on account of disease of the mesenteric glands he remarks, "The evacuations were pultaceous or liquid, of a dull chalky colour, frothing like soap when a stream of water was poured on them."

---

[1] THE LANCET, 1921, i., 743.

It does not necessarily follow that lacteals seen to be dilated in life in a patient on an ordinary diet would remain conspicuous after death. In Gull's case the post-mortem report includes no account of the lacteals, although the mesenteric glands were caseous. In all of the four cases referred to by Dr. Miller an acute illness preceded death, and in two at any rate treatment had included a fat-free diet.

I am, Sir, yours faithfully,
J. A. RYLE.

The Warden's House, Guy's Hospital, Jan. 22nd, 1923.

PYLORIC STENOSIS OF INFANTS.

To the Editor of THE LANCET.

SIR,—We have received a letter from Messrs. Nestlé's and Anglo-Swiss Condensed Milk Co., pointing out to us that a sentence in our recent paper published in THE LANCET of Jan. 13th (p. 64, par. 3) is open to misinterpretation. The sentence is as follows: "If soapy stools are present, then milk with a poor fat content—e.g., skim milk or Nestlé's condensed sweetened milk—is used as previously indicated," and it is pointed out that this might convey the impression that Nestlé's Condensed Sweetened Milk is deficient in fat.

We would like to say, however, that the words "as previously indicated" are a reference to the fact that it is necessary to dilute the milk considerably in order to produce a food with a poor fat content. It would perhaps have made our meaning clearer and left no possible room for doubt if the sentence had read: "If soapy stools are present, then milk of a poor fat content—e.g., skimmed milk or *highly diluted* Nestlé's Condensed Sweetened Milk is used as previously indicated." We are, Sir, yours faithfully,

LEONARD G. PARSONS.
SEYMOUR BARLING.

Birmingham, Jan. 19th, 1923.

SOME THOUGHTS ABOUT ENDOCRINOLOGY.

To the Editor of THE LANCET.

SIR,—There are three classes of people interested in endocrinology: 1. Scientific investigators with critical minds who observe accumulated evidence with dispassionate interest. 2. Persons engaged in attempting to cure disease whose optimism and eagerness to help sway their deficient critical sense until they seize at any straw which seems to point towards success. There is often a love of romance in these people which makes them delight in spinning a misty intellectual mesh which completely obscures any possible facts. This is a large and sincere class, including a mass of general practitioners, most dispensing chemists, a number of consultants, not a few journalists, many oriental medical men. 3. Persons who have realised the commercial possibilities in exploiting the human weakness characteristic of the last-named class. Certain of the firms placing "endocrine" preparations on the market belong to this last class.

Nothing which Dr. Swale Vincent said at the meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine, reported in your last week's issue, was in any way shaken by subsequent speakers; it must be admitted that whether or not his views place an undesirable damper on enthusiasm, whether or not destructive criticism is required, neither fellow observers nor trade proprietors have been able to bring a counter case. One of the longest speeches came from a practitioner who believed in parathyroid. Few reputable firms have placed on the market a parathyroid preparation with the claim that it is potent. Some of the parathyroid extracts sold contain no parathyroid at all, and if they have any effect owe it to traces of thyroid present in them. The speaker referred to asked us to swallow not only parathyroid, but also tales of focal sepsis more incredible than those put forward at even purely clinical discussions. It may be asked how can the general practitioner carry out clinical tests of supposed remedies? It can readily be done if he has the courage to use controls. Every clinical inquiry must have controls—i.e., parallel with each attempt to produce an effect must be a case under absolutely the same conditions with simply *one factor* eliminated. If, in the work on varicose ulcer quoted, there had been a series of cases which had been similarly treated, save that sugar tablets instead of parathyroid had been given, there would be some basis for discussion. The speaker's laboratory companion maintained a lamentable silence as to his method of estimating calcium, an extremely difficult chemical investigation about which the most distinguished chemists are sceptical. The same gentleman's silence as to how he knew he was actually employing parathyroid extract was not impressive.

The exploitation of the public by those commercial firms who pour out inert preparations at high figures should be strenuously fought. The money spent by the public in paying for them and by the proprietors in marketing them would re-build and endow the London hospitals.—I am, Sir, yours faithfully,

Jan. 13th, 1923. A PHYSICIAN.

ROYAL MEDICAL BENEVOLENT FUND.

AT the meeting of the Committee held on Jan. 9th 17 cases were considered and £250 voted to 13 applicants. The following is a summary of some of the cases relieved:—

M.D. Brux., L.S.A. Lond., aged 62, married. Practised in London for 20 years. Owing to chronic neurasthenia and bronchitis, also general weakness, is unable to concentrate on work. Applicant asked the Fund to help towards board and lodging, which up to the present friends provided. He has also been allowed 4*s.* per week pocket-money. Voted £26 in 12 instalments.

M.D. Dub. 1866, aged 61, married. Practised in East London. Owing to severe nephritis with general arterio-sclerosis has been unable to attend properly to his practice, and is now reduced to a small panel bringing in 5*s.* per week and private practice about the same amount. The rent of 16*s.* per week is reduced to half this amount by letting. Voted £26 in 12 instalments.

Widow, aged 50, of M.D. Edin. who practised in Sheffield and died in 1906. Applicant used to take post as companion help, but owing to ill-health has had to give this up. The Guild has been helping this case to the extent of 5*s.* per week, and the Fund has now voted the sum of £12. This case has been relieved five times. Total £45.

Widow, aged 41, of M.R.C.S. Eng. who practised at Liverpool and Swansea, and died in 1914. Owing to ill-health applicant is dependent upon her mother, with whom she lives, and the education of her daughter is paid by various grants from different sources. Applicant has been relieved by the Fund eight times to the extent of £108, and at this meeting was voted £18 in 12 instalments.

Daughter, aged 63, of F.R.C.S. Eng. who practised in London and died in 1885. Through ill-health this applicant has had to give up her profession as nurse and has only a small income of £48 per annum, out of which she has to pay £26 for rent. She has been relieved twice before by the Fund, total £29, and has now been voted £18 in 12 instalments.

Widow, aged 81, of M.R.C.S. Eng. who practised at Devonport and died in 1875. Through the leases of her houses falling in and the death of her son-in-law has found it extremely hard to live on a small income. Her married daughter allows her £45 per annum, and from investments she receives £12. For ground-rent and insurances she has to find £28 per annum. Relieved four times to the extent of £48, the last £12 in 12 instalments January, 1922. The Committee decided to increase this amount, and voted £26 in 12 instalments.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, K.B.E., C.B., M.S., 11, Chandos-street, Cavendish-square, W. 1.

Obituary.

HORATIO PERCY SYMONDS, F.R.C.S. EDIN., M.A. OXF.,

LATE SURGEON TO THE RADCLIFFE INFIRMARY, OXFORD.

WE regret to announce the death of Mr. Horatio Percy Symonds, the well-known Oxford surgeon, which occurred at his home in Oxford on Jan. 16th, and removed one of the best-known personalities from the city.

Horatio Symonds's medical pedigree was a notable one; he was the seventh of his line in uninterrupted descent to practise surgery. The last three of these carried on their work at Oxford, his father, Frederick Symonds, a man of great character and repute, serving many years as surgeon to the Radcliffe Infirmary. H. P. Symonds, or "Young" Symonds, as he continued to be styled by his contemporaries, was educated at Rugby, and, being destined to become a surgeon, was apprenticed to Mr. Winkfield, surgeon to the Radcliffe Infirmary, in 1867. After serving there as a dresser for two and a half years, he went to University College, London, where he came under the influence especially of Berkeley Hill, whose house surgeon he became, Marcus Beck, Vivian Poore, and John (now Sir John) Williams. As a student he went out as a dresser to the Franco-German War in 1870. Returning qualified to Oxford in his early "twenties," he immediately entered his father's practice, and soon stood for election to the staff of the Radcliffe Infirmary, obtaining election in 1878 as honorary surgeon. His zeal and energy in all departments of practice won him prompt recognition, which grew as years went on. Surgery was his bent, and having seen its practice in pre-antiseptic days, his impressionable mind appreciated the great possibilities under conditions of antisepsis. He followed Lister's work with avidity and put into practice in the Radcliffe Infirmary the embodiments of the new teaching. His surgery was essentially bold, original, and successful. He was no mere operator, for he watched his patients with unbroken attention so long as they remained under his care. His diagnosis, born of continuous experience, was accurate and quick, illumined often by a shrewdness that was unsuspected in him. His whole life and work was devoted to the Radcliffe Infirmary, many of whose patients and staff still remember the unremitting toil he gave in its service. He had no hobbies except his work, and took few holidays. In later years he used to go away to Brighton for a few days now and then, but frequently came back before he was expected, to take up again the work he loved best. The enforced retirement from practice in 1914 owing to arthritis was the harder to bear because of his devotion to work, and few things pleased him better in his last years than to hear the news and gossip of the infirmary.

He will be remembered by those who knew him in his best days as a dapper, young-looking man (even in sickness and age this young fresh look did not forsake him), immaculately dressed, with a silk hat and a white flower in his coat. He scarcely ever walked, and therefore was seldom seen far from his carriage, a brougham drawn by two chestnut thoroughbreds. His speech was clear and to the point, and his manner especially to patients brusque and apparently offhand; but that it only served to hide kindness of heart the love of his patients is sufficient testimony. Amongst older Radcliffe patients it is still a matter of pride to have been operated upon by Mr. Symonds.

One of his colleagues writes: Symonds's appointment coincided with the period when Lister's teaching and practice of antiseptic surgery was beginning to bear fruit in London and the provinces, and it was enthusiastically and seriously taken up by him. His mastery of its principles soon enabled him to undertake successfully operations which a few years earlier would have been considered quite unjustifiable because of the risk to life involved. A constant reader of the current surgical literature of the day, he was always to the fore with new methods and ideas and ever ready to put them into practice. Never standing still at a time when great changes were coming over surgery, he kept the surgical work of the hospital not only abreast of the times but in front of that of many provincial hospitals. A bold, skilful, and speedy operator, he was the pioneer at Oxford of many of the operations that are now being performed daily. More than one of his house surgeons have spoken of his unfailing punctuality, and all his colleagues would agree as to his driving force in the conduct and general management of the infirmary. Many of his house surgeons will remember with gratitude the kindly help and encouragement and the opportunities he gave them of acquiring a practical knowledge of surgery. He was a most regular attendant at our medical meetings in Oxford in connexion with the Oxford Medical Society and the Oxford division of the British Medical Association, and was very helpful both in reading and showing cases and taking an active share in the discussions. In 1904, when the British Medical Association met at Oxford, he was President of the Surgical Section. In the early days of the war he was struck down with arthritis of the hip, which progressed so rapidly that he was unable to get about and was compelled to resign his appointment as surgeon to the Third Southern General Hospital, work for which he was eminently suited. As this disease progressed it became more and more impossible for him to get about, and for the last few months of his life his sight failed him. He fought against these increasing infirmities with great courage.

ALFRED MAXWELL WILLIAMSON, M.D., C.M., B.SC. EDIN.,

MEDICAL OFFICER OF HEALTH FOR EDINBURGH.

THE death of Dr. Maxwell Williamson at the age of 63 has robbed the public health service of an able administrative officer. He was born at Leith in 1859, the son of a local medical man, and after training as a nautical engineer took up medicine and qualified at Edinburgh in 1888. Three years later he became assistant to Sir Henry Littlejohn, whom he succeeded on his retirement in 1908, after having in the meantime served the city well as its chief sanitary inspector. Thus when Williamson became medical officer of health he found the administrative machinery already established on a strong basis. Being a man of unbounded energy, he expected everyone of his staff to be equally alert, and his efforts at controlling sudden outbreaks of dangerous infectious disease were conspicuous by their thoroughness. But he was seldom in the limelight of public health conferences; he did not like public functions, and preferred to spend his time leaving good foundations of administrative work behind him. He had high ideals, and he never rested until he gained his way. The completeness of the child welfare and venereal diseases schemes in Edinburgh bear witness to his thoroughness. In tuberculosis he did not have to create the machinery, for the tuberculosis scheme, founded by Sir Robert Philip, was taken over by the municipality as a going concern and formed an excellent groundwork of success. Williamson's striking reports on housing compelled the local authority to take drastic action with improvement and reconstruction schemes, and before he died he had set the wheels in motion for dealing with one of the worst areas in the city. On temperance questions he was an emphatic reformer, and many slum-dwellers will miss the Sabbath mission which he conducted with great regularity. Students now scattered throughout the world have Dr. Williamson to thank for a good grounding in sound administrative ideals.

Dr. Williamson remained unmarried, giving his whole time and interest to the fulfilment of his office.

Medical News.

Society of Apothecaries of London.—At examinations held recently the following candidates were successful:—

Surgery.—G. G. Brown, Charing Cross Hospital; M. P. Parker, Royal Free and St. Mary's Hospitals; R. F. A. Philpott, St. George's Hospital; H. M. White, Leeds.

Medicine.—B. Basuny (Section I.), Cairo; L. A. Daly (Section II.), St. Bartholomew's Hospital.

Forensic Medicine.—H. J. Adams, Middlesex Hospital; B. Basuny, Cairo; C. S. Laurence, Sydney and Bristol.

Midwifery.—B. Hart, Sheffield; W. M. Jones, St. Bartholomew's Hospital; C. S. Laurence, Sydney and Bristol.

The diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: G. G. Brown, M. P. Parker, and R. F. A. Philpott.

University of London.—A course of eight lectures on the Physiology of the Cortex as Investigated by the Method of Conditioned Reflexes will be given by Dr. G. Anrep at University College, Gower-street, London, W.C. 1, at 5 P.M., on Fridays, from Jan. 26th to March 16th. Attendance at this course is recognised in connexion with the B.Sc. (Honours) degree in Physiology. Admission is free.

Queen Charlotte's Hospital: Midwifery Lectures.—A series of lectures in midwifery subjects will be given by the members of the hospital staff at 5 P.M. on Thursdays, commencing on Feb. 1st, when Dr. C. Hubert Roberts will speak on Ante-partum Hæmorrhage. On Feb. 8th Dr. J. Bright Banister will discuss Heart Disease in Pregnancy. Mr. Aleck W. Bourne will deal with Acute Fevers in Pregnancy on Feb. 15th; and Dr. Trevor B. Davies with Clinical Aspects of Abortion on Feb. 22nd. On March 1st Dr. Louis C. Rivett will lecture on Delay in Labour; and on March 8th Dr. Leonard Phillips on Common Unrecognised Difficulties in Obstetrics. These lectures are intended for students and practitioners and are free.

Medical Society of London.—The programme for the second half of the session has now been issued. On Feb. 12th, at 8.30 P.M., a discussion on Psycho-therapeutics will be opened by Dr. F. Farquhar Buzzard, followed by Dr. William Brown, Dr. M. B. Wright, Dr. S. A. K. Wilson, Dr. David Forsyth, and others. On Feb. 26th, at 8.30 P.M., a discussion on the Various Methods of Treatment of Cancer of the Tongue will be opened by Mr. James Berry, followed by Mr. W. Clayton Greene, Mr. Wilfred Trotter, Mr. G. Gask, Mr. Gordon Taylor, Mr. A. Edmunds, Mr. H. S. Clogg, and others. On March 12th, at 8.30 P.M., a discussion on the Value of Laboratory Investigation in Diseases of the Liver and of the Pancreas will be introduced by Dr. W. R. Langdon Brown, followed by Prof. F. S. Langmead, Dr. Mackenzie Wallis, Dr. J. M. McNee, Dr. E. A. Dodds, Dr. G. A. Harrison, Mr. H. E. Griffiths, and others.

The Lettsomian lectures on Carcinoma of the Rectum will be delivered at 9 P.M. on Feb. 19th, March 7th, and March 26th, by Mr. W. E. Miles. The annual oration will be delivered on May 14th by Dr. J. W. Carr.

Fellowship of Medicine and Post-Graduate Medical Association.—The Fellowship of Medicine have arranged a further series of post-graduate lectures, open to members of the profession, to be given, by the kind permission of the Royal Society of Medicine, in the West Lecture Hall, 1, Wimpole-street, during February and March. The opening lecture on Wednesday, Feb. 7th, at 8.30 P.M., will be given by Mr. J. P. Lockhart-Mummery on Diverticulitis, and others will follow by Dr. G. A. Sutherland, Mr. Cecil Rowntree, Dr. George Riddoch, and Mr. A. J. Walton. Copies of the complete programme will be forwarded on application to the secretary to the Fellowship of Medicine, 1, Wimpole-street, W. 1.

A course of six practical lecture-demonstrations on Certain Diseases of Children will be held during February at the Children's Clinic, Western General Dispensary, Cosway-street, N.W. 1, on Tuesdays and Fridays at 5 P.M. The first will be given on Tuesday, Feb. 13th, by Prof. Sir William Bayliss on The Physiology of Digestion; lectures by Dr. Bernard Myers will follow, the concluding lecture on Friday, March 2nd, being devoted to The Nervous Child, as Seen in General Practice. The fee for the course is one guinea, and copies of the syllabus can be obtained from the secretary to the Fellowship of Medicine, 1, Wimpole-street, W. 1.

Vocational Training of Tuberculous Ex-Service Men.—The Ministry of Health has issued a circular (No. 371, England, dated Jan. 20th) to county and county borough councils, tuberculosis joint committees, and metropolitan borough councils, referring to circular 307, dated April 29th, 1922, relative to the special arrangements for the vocational training of ex-Service men suffering from tuberculosis. It has been decided to utilise, under those arrangements, and in addition to the accommodation described in that circular, 100 places provided at the Preston Hall Sanatorium and Training Colony, Aylesford, Kent, by the Industrial Settlements (Incorporated) for Disabled Soldiers and Sailors. The courses of training at Preston Hall will comprise: (1) market gardening, poultry and pig-keeping, &c. (70 places); (2) rural carpentry (30 places). The general provisions of circular 307 will apply in regard to cases proceeding to Preston Hall under the vocational training scheme; payment for such cases will be made by the Minister of Health direct to the authorities of the institution. Cases will be selected by the Ministry of Pensions from the approved applicants under the scheme; tuberculosis officers will be informed by the Deputy Commissioners of Medical Services (Tuberculosis) of the cases selected, and asked to arrange for their admission. Many of these cases will already have been approved for a course of training at another institution, and their names placed on the latter's waiting list. A tuberculosis officer should take steps to secure admission of the case to Preston Hall without delay, unless arrangements have actually been made to send the case on a specified date to the institution for which he was originally approved. In the latter event the tuberculosis officer should inform the D.C.M.S. (Tuberculosis) accordingly. In some cases tuberculosis officers will not be in possession of the medical reports on Form M.P.M.S.D. 119, but this should not be allowed to delay the admission of cases to Preston Hall under this scheme. In these cases the reports should be recovered from the medical superintendents of the institutions previously chosen and then forwarded to the medical superintendent of Preston Hall, who should be informed that the case has been approved by the D.C.M.S. (Tuberculosis) for vocational training at that institution. The Minister relies on the coöperation of tuberculosis officers in dealing promptly with cases selected for vocational training at Preston Hall. These men are entitled to remain in the institution until completion of a special course of vocational training, the duration of which is not to exceed 12 months. Such cases are not to be confused with cases sent for treatment combined with training (in accordance with paragraph 12 of Memorandum 30/T); the latter are sent primarily for treatment, and the length of their stay is subject to review by the Ministry of Pensions, as in the case of other ex-Service men receiving treatment in residential institutions.

University of Manchester.—Miss Muriel M. Nutt, Nat. Sci. Trip. (Cambridge), has been appointed Demonstrator in Bacteriology.

Guild of Health.—A public lecture on Psychotherapy and Religion will be delivered by Rev. L. W. Grensted at the Central Hall, Westminster, London, S.W., on Jan. 31st at 8.15 P.M., Dr. William Brown presiding.

The fifth annual reunion dinner for overseas medical officers, West Lancashire area, will be held on Thursday, Feb. 8th, at 7.30 P.M., at the Exchange Station Hotel, Liverpool. Tickets may be obtained from the hon. secretary, Dr. J. W. Burns, 49, Rodney-street, Liverpool.

Scottish Poor-Law Medical Officers' Association.—In their report for 1922 the Committee of the Association state that vacant appointments have again been under the average during the year, and were chiefly owing to deaths and removals from the districts. Correspondence has taken place with members in regard to medical officers supplying drugs out of their salaries. Advice was given that this was illegal, except in cases where it was specifically mentioned in the agreement that drugs were to be supplied out of the salary; further, that the Scottish Board of Health did not approve of drugs being included in the salary. Also, in regard to fees for statutory visits to boarded-out mental defectives, advice was given that a fee was chargeable in each case where the mental defective belonged to an outside parish, and that a fee was also chargeable in cases belonging to their own parish, except where the agreement said that such visits were to be included in the salary. The Scottish Committee of the British Medical Association interviewed the Scottish Board of Health in regard to tenure of office, but failed to move that board. It now remains to approach the B.M.A. Council in London, and endeavour to get them to approach Parliament by a Private Bill. The Committee have tried in past years to get the existing anomalous position rectified, but so far without result; they point out that it is manifestly unfair that English medical officers should have an appeal against injustice, and that medical officers in the crofting counties of Scotland should have practically the same protection, while medical officers in the rest of Scotland hold their appointments at the absolute caprice of parish councils. Parliament has now passed a Bill granting superannuation to all local Government officials, medical officers included. The Act is contributory in nature, but voluntary on the part of parish councils.

FEDERATION OF MEDICAL AND ALLIED SERVICES.—A meeting of the Executive Council will be held at the offices of the Federation, 12, Stratford-place, London, W. 1, on Tuesday next, Jan. 30th, at 5 P.M., when the report of the Finance Committee will be submitted and indications of further activities will be mentioned. The Federation proposes to make certain representations upon the questions of exemption from legacy and succession duty, and of remission of local taxation, in respect of voluntary hospitals.

ROYAL INSTITUTION OF GREAT BRITAIN.—The Friday evening discourse on Feb. 2nd will be delivered at 9 P.M. by Mr. Charles F. Cross, F.R.S. The subject is Fact and Phantasy in Industrial Science. On Feb. 1st, at 3 P.M., Dr. I. M. Heilbron will give his first lecture on the Photosynthesis of Plant Products.

THE IVORY CROSS: FIRST SAINT APOLLONIA DINNER.—The Ivory Cross is to hold a banquet on Friday evening, Feb. 9th, at the Hotel Victoria, Northumberland-avenue, London, W.C. 2, to commemorate Saint Apollonia, who was recently installed as the patron-saint of dentistry. The date was selected by the committee, of which Sir Acton Blake is chairman, because Feb. 9th is the feast-day of this saint. Tickets (price £1 1*s.*) can be had from any member of the Dental Committee, or at the offices of the Ivory Cross, 10, Henrietta-street, London, W. 1.

THE LATE DR. JOSHUA J. COX.—Dr. Cox, who died suddenly on Jan. 17th, was born in Ireland in 1854 and was educated at the University of Edinburgh, where he obtained the degree of M.B. in 1875, and that of M.D. in 1881, becoming F.R.C.S. Edin. in 1885. He settled in Eccles in 1880, where he lived for several years and secured a large practice. He was for many years a consulting physician to the Northern Hospital, the Victoria Dental Hospital, Manchester, and other institutions in and around Manchester. Some years ago he went to live in Buxton, but kept up his consultation practice in Manchester. At the outbreak of the war Dr. Cox was appointed president of the Medical Recruiting Board in Manchester, and later a Commissioner of Medical Services for the North-Western Division; for these and other services he was awarded the military O.B.E. Dr. Cox always took keen interest in the diseases of children, and during his residence in Buxton rendered valuable service to the Derbyshire and Buxton Cottage Hospitals.

IRISH POOR-LAW LEGISLATION.—Last week the Minister for Local Government introduced in Dail Earann the Local Government (Temporary Provisions) Bill. The text of the Bill is not yet published, but the Minister stated that its object was to legalise the various reforms in Local Government that had been carried out in the past few years. Prior to the establishment of the Free State, under the advice of the then Local Government Department of Dail Earann, a number of reforms were carried out in several counties. Poor-law unions and workhouses and district hospitals were abolished and health administration was organised on a county basis. Until the Bill now before Parliament is passed, these changes have no legal authority. In introducing the Bill the Minister renewed his promise that permanent legislation would be subsequently introduced to deal with Local Government affairs. It is recognised that the reforms so far made are not perfect in themselves and are by no means adequate for dealing with the whole situation.

THE LATE DR. A. P. SHERWOOD.—The death occurred at Eastbourne on Jan. 17th, at the age of 71, of Dr. Arthur Paul Sherwood, who had been in practice at Eastbourne for 44 years. He had only retired from practice two days before his death, and was making arrangements to take up his residence in the country. Dr. Sherwood qualified M.R.C.S., L.R.C.P. from St. George's Hospital in 1873, and held the appointments of house physician at his hospital and house surgeon at the Bedford General Infirmary, and became M.D. Durham in 1891. He was a founder and one of the first medical officers of Princess Alice Memorial Hospital at Eastbourne, and for 25 years was treasurer and secretary of the local Provident Medical Association. During the war he did valuable work as medical officer of Sussex 15 V.A.D., and at the local Red Cross hospitals. He was a prominent Freemason and held high provincial honours.

INDEX TO "THE LANCET," VOL. II., 1922.

THE Index and Title-page to Vol. II., 1922, which was completed with the issue of Dec. 30th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Wednesday, Jan. 31st.

SOCIAL EVENING: at 8.30 P.M.
Fellows, Members of Sections, Associates and their friends will be received by the President, Sir William Hale-White, and Lady Hale-White, at 8.30 P.M.
Prof. William Wright will deliver a short Address at 9 P.M on "Leonardo da Vinci."
The Library will be open, and various objects of interest will be exhibited. Music, light refreshments, and smoking.

Thursday, Feb. 1st.

OBSTETRICS AND GYNÆCOLOGY: at 8 P.M.
Specimens:
Dr. Fairbairn: (*a*) A Necrotic Fibro-adenoma in a patient of 74, simulating Cancer of the Body. (*b*) Cyst of the Uterine Cornu.
Mr. Beckwith Wbitehouse: Slides from a case of Multiple Cysts of the Vagina of Lymphatic Origin, simulating Adenomatosis Vaginæ.
Short Communications:
Dr. W. R. White-Cooper and Mr. H. K. Griffith: (1) A case of Inversion of the Uterus occurring in the Third Week of the Puerperium. (2) A case of Obstructed Labour due to Contraction Ring.
Mr. Beckwith Whitehouse and Dr. Henry Featherstone: A Note on the Use of Spinal Anæsthesia with Tropococaine in Cases of Cæsarean Section.
Paper:
Dr. S. Cameron: Cæsarean Section.

Friday, Feb. 2nd.

LARYNGOLOGY: at 4.45 P.M. (Cases at 4 P.M.)
Cases and Specimens will be shown by—
Mr. A. J. Wright, Sir StClair Thomson, Mr. Andrew Wylie, Dr. Nicoll Rankin, Mr. Archer Ryland, Mr. Vlasto, Sir James Dundas-Grant, and Dr. Douglas Guthrie.
Lantern Demonstration:
Dr. Irwin Moore: Operative Procedures in the Treatment of Bilateral Paralysis of the Abductor Muscles of the Larynx, with special reference to a new method by means of which, it is suggested, the air-way may be reopened and the patient de-cannulated.

ANÆSTHETICS: at 8.30 P.M.
Paper:
Dr. J. Strickland Goodall: Some Cardiovascular Conditions in Relation to Anæsthesia. Sir Bernard Spilsbury, Dr. Goodman Levy, and others have promised to take part in the subsequent discussion.

EPIDEMIOLOGY AND STATE MEDICINE: at 8 P.M.
Presidential Address:
Dr. R. J. Reece: Progress and Problems in Epidemiology.
It is proposed that Members of the Section should dine together before the meeting at 6.30 P.M. at Pagani's Restaurant, 42, Great Portland-street, W. Members intending to dine are requested to give notice as soon as possible to Dr. Greenwood, National Institute of Medical Research, N.W. 3.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.
MONDAY, Jan. 29th.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Addison: Surgical Wards. 4 P.M., Mr. Bishop Harman: Senile Failures of Vision.
TUESDAY.—10.30 A.M., Dr. Paterson: Demonstration of Medical Cases. 12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Mr. Tyrrell Gray: Surgical Wards.
WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 2.30 P.M., Mr. Donald Armour: Surgical Wards. 4 P.M., Dr. Archer: Demonstration of Renal Function Tests.
THURSDAY, Feb. 1st.—10 A.M., Dr. Grainger Stewart: Neurological Department. 12 noon, Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. Bishop Harman: Eye Department.
FRIDAY.—12 noon, Dr. Flett: Radiology. 3 P.M., Mr. Sinclair: Surgical Cases. 4 P.M., Dr. Burrell: Demonstration of Artificial Pneumothorax.
SATURDAY.—9 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 11 A.M., Mr. Maingot: Surgical Pathology.
Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M.: In-patients, Out-patients, Operations, Special Departments.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's General Hospital, Tottenham, N.
THURSDAY, Feb. 1st.—8 P.M., Dr. F. G. Crookshank: Some Types of Defective Children (Lantern Lecture) followed by Discussion to be opened by Dr. Sundell.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: JAN.–MARCH, 1923.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, Jan. 29th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Lecture:—Some Aspects of Nervous Diseases: Dr. James Taylor.

TUESDAY, Jan. 30th.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Lecture:—Myopathy: Dr. Adie.

THURSDAY, Feb. 1st.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Lecture:—Visceral Carcinoma and Secondary Involvement of the Nervous System: Dr. Walshe.

FRIDAY, Feb. 2nd.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Lecture:—Myelitis: Dr. Saunders.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

NEURO-PATHOLOGY.

MONDAY, Jan. 29th.—12 noon, Cerebro-Spinal Fluid: Dr. J. Godwin Greenfield.

N.B.—A Course of Lectures in the Anatomy and Physiology of the Nervous System will be given if there are sufficient entries for it.

The fee for the whole Course, including Anatomy and Physiology, is £12 12*s.*, but these Lectures may be taken separately for a fee of £4 4*s.* Course without Anatomy and Physiology Lectures will be £10 10*s.* Any part of the Course may be taken separately at a special fee. Special arrangements will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the office on entering for the Course.

C. M. HINDS HOWELL, Dean of Medical School.

HOSPITAL FOR SICK CHILDREN, Great Ormond-st., W.C.

THURSDAY, Feb. 1st.—4 P.M., Dr. Poynton: Progressive and Malignant Endocarditis.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.

THURSDAY, Feb. 1st.—5 P.M., Dr. W. Knowsley Sibley: Alopecia and its Treatment.

MANCHESTER ROYAL INFIRMARY.

TUESDAY, Jan. 30th.—4.15 P.M., Mr. P. R. Wrigley: Carcinoma of the Colon.

FRIDAY.—4.15 P.M., Mr. J. Morley: Applied Anatomy of the Gastro-Intestinal Tract.

ST. MARY'S HOSPITALS, MANCHESTER. POST-GRADUATE LECTURES (at Whitworth-street West Branch).

FRIDAY, Feb. 2nd.—4.30 P.M., Dr. Fletcher Shaw: Hæmorrhage Occurring Apart from Pregnancy.

SALFORD ROYAL HOSPITAL, MANCHESTER.

THURSDAY, Feb. 1st.—Dr. W. R. Addis: The Diagnosis of Malignant Disease of the Uterus.

MANCHESTER FRENCH HOSPITAL, 24, Acomb-street, Whitworth Park.

THURSDAY, Feb. 1st.—4.30 P.M., Mr. Howard Buck: The Treatment of Rupture.

Appointments.

CRAIG, GEORGINA S., M.B., Ch.B., D.P.H. St. And., has been appointed Assistant Medical Officer for Cheshire.

EVANS, EVAN, M.B., B.S. Lond., Medical Officer of Health for Lampeter.

HELM, W. A., M.B., Ch.B. Manch., Assistant Medical Officer for East Lancashire Tuberculosis Colony.

NUTT, MURIEL M., Demonstrator in Bacteriology at Manchester University.

SMITH, ALICE B., M.B., Ch.B. Edin., L.M., D.P.H. Dub., Third Assistant Resident Medical Officer to the Salford Union Infirmary.

THYNNE, MILDRED A., M.B. Lond., L.R.C.P. Lond., M.R.C.S., Assistant Medical Officer for Maternity and Child Welfare to the Bermondsey Borough Council.

Certifying Surgeons under the Factory and Workshop Acts: BURROWES, H. A., M.D. Lond. (Looe): CRAIG, A. C. C., M.B., Ch.B. Edin. (Kirkcudbright).

Vacancies.

For further information refer to the advertisement columns.

Aylesbury, Royal Bucks Hospital.—Res. M.O. £150.

Battersea Borough Council.—Asst. M.O. £550.

Bolingbroke Hospital, Wandsworth Common, S.W.—Res. M.O. £200.

Bristol General Hospital.—Hon. Phys. Accoucheur. Also Asst. Phys. Accoucheur.

Bristol Royal Infirmary.—H.P.s and H.S.s, &c. Each £120. Also Hon. Ophth. Reg.

Canterbury, Kent and Canterbury Hospital.—Res. M.O. £175.

City of London Hospital for Diseases of Chest, Victoria Park, E.—Asst. M.O. £100. Also Phys. to Out-patients.

City of London Mental Hospital, near Dartford, Kent.—Second Asst. M.O. £350.

Croydon County Borough.—M.O.H. £1300.

Croydon General Hospital.—Hon. M.O. for X Ray Dept.

Durham County Hospital.—H.S. £200.

India, Countess of Dufferin's Fund, Women's Medical Service.—Two Med. Women. Rs.450 p.m.

Liverpool Royal Children's Hospital.—Two Res. H.P.'s and Two Res. H.S.'s. Each £90.

Liverpool, Royal Southern Hospital.—Res. Cas. O. £150. Also Two H.P.'s and Three H.S.'s. Each £100.

London Lock Hospital, Dean-street, and Harrow-road.—Surg. Reg.

Manchester, Monsall Fever Hospital.—Med. Supt. £750.

Middlesex Hospital Medical School—Eight Registrars.

Napsbury Mental Hospital.—Jun. Asst. M.O. £546 14*s.*

Northampton County Borough Education Committee.—Asst. Sch. M.O. and Asst. M.O.H. £600.

Norwich, Norfolk and Norwich Hospital.—H.S. £150.

Preston and County of Lancaster Queen Victoria Royal Infirmary.—Res. Surg. O. and H.S. £225 and £200 respectively.

Prince of Wales's General Hospital, Tottenham, N.—Hon. Asst. Gynæcologist.

Rochdale Infirmary and Dispensary.—Jun. H.S. £200.

Rotherham Hospital.—Jun. H.S. £150.

Royal Dental Hospital of London, Leicester-square, W.C.—Two House Anæsthetists. 10*s.* 6*d.* per attendance.

Royal Eye Hospital, St. George's Circus, Southwark, S.E.—Hon. Asst. S. Also Clin. Assts.

Royal London Ophthalmic Hospital, City-road, E.C.—Refraction Asst. £100.

Salford Royal Hospital.—Anæsthetist. £1 1*s.* per session. Also Hon. Asst. Radiographer.

Sheffield University.—Asst. Bacteriologist and Demonstrator in Pathology. Each £300.

South London Hospital for Women, Clapham Common, S.W.—Sen. H.S. £100. Also Second H.S. £50.

Stoke-on-Trent, North Staffordshire Infirmary.—H.S. £200.

Surrey Dispensary, Great Dover-street, Southwark, S.E.—S. 50 guineas.

University College Hospital, Gower-street, W.C.—Asst. in Child Welfare. £50.

University of London.—External Examiners, &c.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Hon. P. or S. for Dis. of Skin.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Hon. Asst. S.

Worcester County and City Mental Hospital, Powick..—Jun. Asst. M.O. £300.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Canterbury (Kent), New Mills (Derby), Stourbridge (Worcester), Gravesend (Kent), Bucksburn (Aberdeen), Thirsk (York).

Births, Marriages, and Deaths.

BIRTHS.

BISSET-SMITH.—On Jan. 20th, 1923, at 34, Chester-square, Ashton-under-Lyne, the wife of Dr. R. Bisset-Smith, of a son.

HEPPER.—On Jan. 16th, at Frimley, Surrey, the wife of Dr. John E. Hepper, of a son.

MATHESON.—On Jan. 18th, at Heaton-road, Newcastle-on-Tyne, the wife of Dr. James Matheson, of a daughter.

MERRICK.—On Jan. 16th, at Edith-road, West Kensington, London, W., the wife of R. Warren Merrick, M.D., of a son.

MARRIAGES.

MARTIN—BLANDY.—At St. Pancras Church, London, James Purdon Martin, M.A., M.D., M.R.C.P., to Marjorie Ada Blandy, M.B., M.R.C.P., younger daughter of the late Richard Blandy, Madeira and Jersey.

DEATHS.

CHANCE.—On Jan. 20th, at Clairview-road, Streatham, suddenly after long illness, Robert F. Chance, M.R.C.S., L.R.C.P., aged 54.

SHERWOOD.—Very suddenly, Arthur Paul Sherwood, M.D., of Eastbourne, in his seventy-second year.

WHITELEGGE.—On Jan. 19th, at his residence, Riverside, Saltford, Som., Surgeon-Captain William Arthur Whitelegge, B.A., M.D., R.N. Retd., aged 61.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

ANATOMICAL TERMINOLOGY.

BRITISH OR CONTINENTAL?

BY A LONDON TEACHER.

THE language of anatomy is a matter of wide interest to the medical profession as well as to those who spend their lives in anatomical work. The mildest anatomist shows a tendency to get savage when the matter is raised, but the majority of medical men do not seem to appreciate to what an extent it may affect their own work.

"*The Language of Anatomy.*"

Some little time ago there appeared in the form of S.P.E. Tract No. IX,[1] a treatise on the language of anatomy as viewed by Dr. Cuthbert Morton, edited with an introduction by Dr. Robert Bridges. Dr. Morton's efforts to remedy what he considers to be the defects of English anatomical terminology are well known to many; we may or may not find it easy to see how the path of the anatomical student could be made more rosy by the adoption of Dr. Morton's anatomical language—or, indeed, of any system other than the particular one he may be using—but this does not lessen the interest felt in perusing this little tract, nor keep one from agreement with much of what is said in it. Perhaps those who are not actually concerned in the detailed discussions on terminologies are able to take a detached and wide view of the whole question of change, and it is interesting to note that "the import of this disquisition is to condemn the action of those who are moving to introduce a formal Latin international terminology into the British schools of anatomy, on the false notion that it will be of service to international science."

This condemnation appears to be justifiable. Both popular and scientific languages must be subject to the process of evolution, if they are alive, and so long as they are alive, and no language reaches its final form till it is dead. Who can tell what the subtle forces are which slowly change a common tongue in one direction in one country, and in another under another sun? But whatever these may be there is little doubt that if, by some miracle, a common tongue were established to-morrow, the inevitable evolutionary changes would begin to alter it in each country as it was learnt, and in a few years or a few centuries the number of distinct languages would tally with that of the countries. The same applies to anatomical terminology, and each country must and will have its own ideas of what terms it likes to use in this matter, as in its daily speech. The S.P.E. tract goes perhaps even further than this, for it contends that "all scientific nomenclature must have its basis in every national language, and that whatever classical or foreign terms are introduced should be as far as possible adapted to the national speech."

Evolution in Nomenclature.

There are many anatomical terms that call for revision, as every anatomist admits, because they have become inappropriate. This is one of the things of which evolution will take account. Its action is slow but none the less sure, and many of us, looking back to our student days, can see that even in that relatively short time a distinct change is recognisable in nomenclature which has been slowly and quietly progressing in the interval, not as the result of any violent upheaval from without, but from inevitable internal evolution. Other terms are sometimes said to be confusing. No doubt a theoretical case of this sort might be made out about certain descriptive terms, but we doubt whether in practice confusion ever arises in the minds of an audience from the use of these terms by a competent teacher. No language can be made fool-proof, and none can be rendered malice-proof. Moreover, it must be remembered in this connexion that the general education of the audience has much to do with it; the writer who speaks of "corpora quadrigemina bodies" has got somewhat mixed in his terms, but the fault lies in the deficiencies of his education and cannot properly be laid at the door of anatomical nomenclature. The general opinion among teachers of anatomy seems to be that students have little difficulty in acquiring the terms in use, and the difficulty they may find in grasping the meaning of these terms is largely if not altogether due to lack of general education.

Proper names are in most cases ornaments without which anatomy can progress very well, but here and there they are so closely interwoven with a part, are in fact such popular favourites, that they will probably withstand all assaults on their positions. Speaking of some of these, the S.P.E. tract says: ". . . . Such terms have some of the best qualities of good nomenclature; they are traditional, definite, picturesque, and easily remembered; it would therefore be foolish to oust them without very good reason, but it is foolish to keep them when they are useless. In medicine a proper name is often convenient; although Bright's disease might be called "nephritis' without loss, it would be difficult to find a short descriptive name for Addison's disease. . . . ." We get a notion from this about the possible value of a proper name, but no light is thrown on the hidden factors making for popularity or distaste for names; we would object strongly to the loss of Poupart's ligament or Hunter's canal, but we could hear without a sigh of the removal of the muscle of Zaglas or the veins of Zuckerkandl from the list of anatomical structures.

Latin as a Medium of Intercourse.

As for the use of Latin, we have to distinguish between Latin words which have become English, perhaps without change, and those which are used definitely as a different language. Thus the Latin adjective *biceps* has become a good English noun in practice, whereas to call the muscle *Musculus biceps* would be to describe it to an English audience in a foreign tongue. This would be a retrograde step, going backwards some few centuries, and it is hard to see any justification for it, or any benefit which might with reason be supposed to accrue from it. The critical remark in the tract, on a supposed advantage often urged on its behalf, puts the matter well: ". . . . It is a strange mistake to suppose, as some argue, that by use of the Latin forms of the Latin words of the international we shall in any way facilitate 'international intercourse.' There is nothing to be gained by it, for unless we shall all talk Latin again there can be no 'intercourse' without the common knowledge of a modern language; a sprinkling of intelligible scientific terms in a discourse the language of which is unintelligible can serve no purpose whatever; and if one knows enough of the language to understand the discourse, then the naturalised scientific terms will be as easy to understand as their full Latin equivalents. . . ." As a matter of fact the professional anatomist has no difficulty in understanding what his foreign colleagues mean when they use their national nomenclature, and if he, the one mainly and daily concerned, is thus found to have no need for an international nomenclature, the ordinary student might be said to have no use for it.

Speaking of the Austro-German terminology the tract says: "Thus Professor Barker, of Washington, states that 'The terms are all in correct Latin,' which can easily be disproved, and also that each 'name has a definite and easily ascertainable meaning,' which is truly remarkable if the terms are 'merely memory signs and need lay no claim to description or to speculative interpretation. . . .' This terminology suffers from an almost mediæval servitude to latinity." It would seem that there is little need for internationalism, and that the British terminology may in general be safely left to evolve along its own lines. The large amount of anatomical literature circulating in the world is enough to ensure that the various lines of evolution do not lose touch with one another, and each will preserve what it finds good. But this cannot be permanently forced by artificial methods, and it is not natural to expect any nation to yield up the evolution of its terminology to another nation or nations.

Yet British anatomists may help the British evolution by small excisions and alterations where the need is apparent; but the help, if it is to be helpful, will have to be done with loving care and within very narrow limitations.

WHAT GERMANY'S RISING PRICES REALLY MEAN.

The following statement, written by the statistical authority in a mid-German community, has been sent to us by the Friends' Council for International Service.

BY the "increased cost of living" in Germany many people merely take to mean the raising of prices. In reality rising prices do not of necessity mean this; it is the want of relationship between the general level of prices and the national income of the population, which of course takes different aspects in individual strata, circles, and professions within the population. While I do not attach much importance to so-called index figures, &c., it must be recognised that they express the general trend of events, and I may mention here that the index figure of the Reich for the cost of living, regarding food, clothing, lighting, heating, and housing, developed from about 600 at the beginning of 1920 to about three times that amount (1800) at the beginning of 1922, and has now reached over 40,000—about 70 times as much as the figure of the beginning of 1920.

I have myself calculated a new index figure, which I call a "calories index figure" and which expresses the price per 1000 calories from the 26 foodstuffs on which the Reich calculation is based. This showed that 1000 food units from the foodstuffs most commonly in use cost about 40 pfennige before the war. Against this 1000 calories cost—

	Pfennige.		Pfennige.
1920 in Feb.	384	1921 in Dec.	832
,, ,, July	521	1922 ,, July	2,810
,, ,, Dec.	447	,, ,, Sept.	5,209
1921 ,, July	597	,, ,, Nov.	17,518

Thus what could be bought in the way of foodstuffs in the last years before the war at 40 pfennige, now costs 175 marks.

Looking at the meaning of the "increased cost of living" in the light of the foregoing, it will be seen that with this increase the purchasing power of the consumer rapidly decreases, while salaries and wages cannot by any means be raised correspondingly, otherwise there would be no "increased cost of living." The high figures for the salaries of officials, which are so much commented upon abroad, are a great delusion. They do not come up to the very modest pre-war salaries of German officials by a long way.

In the same way as the old people gradually literally starve to death, if they cannot be assisted by relations or friends, nowadays even children in the first years of their life, who are more easily nourished, are beginning to suffer from the increased cost of living, in view of the fact that a quart of milk which cost about 20 pfennige before the war, will now soon cost little less than 200 marks in many of the large towns. With the general progress of the increased cost a certain levelling of salaries and wages inevitably results; the combines of different kinds of industries and manufactories, as well as of the consuming public, gradually do away with the law of supply and demand, and from this results a gradual extermination of the so-called intelligentsia.

In Russia large sections of the intelligentsia are reported to have been forcibly destroyed; with us conditions only differ as to outward form. By intelligentsia I by no means only refer to people with a university education, but to all those who are above the average prevailing in their respective trade or profession. In the first line of these I would put the intelligentsia of labour. Added to this, the activities of scientific institutions are being increasingly hampered. Research will gradually cease, if it is considered that a sheet of ordinary writing paper can hardly be had for less than 10 marks, and that scientific treatises, evolved with the utmost difficulties, cannot be published in scientific circles, much less to the public at large, on account of the cost of printing.

The increased cost and decline in the value of our money abroad is followed by a reduction in the purchase of raw materials. This reduction in imports combined with the high cost of fuel, and its scarcity on account of reparations in kind, must at no distant date lead to a collapse. To mention some trifling examples: The stoneware industry suffers especially from the high price of fuel. A common egg-cup can still be bought in a shop for about 75 marks; new stock are charged at 475 marks a piece, and could not be sold at less than 600 marks retail. A very plain bedroom suite which could be bought last year for 6000 marks costs to-day no less than 260,000 marks in consequence of increased charges for wood, transport, and labour. The ever-rising prices of skins, which are influenced by the international skin and leather market, have so damaged the shoe industry that many factories are working short time—i.e., only a few days per week. More especially high prices are prejudicing the textile market. Here raw materials are already so costly that manufacturers are scarcely able to buy them, and the finished articles may assume prices which the mass of the population is quite unable to afford. Thus it will not be a matter for surprise that school doctors in the large towns report that they frequently examine children who have no underclothes whatever.

From the educational point of view, the prices of books are well known to you. The simplest books hardly ever cost less than 1000 marks, and as to music, simple piano scores, which could in pre-war times be bought for a few marks in popular editions, now fetch 50,000 marks and more. The prices for school copy-books for children are nowadays over 100 marks, against 5, 10, or 15 pfennige pre-war, so that, I am told, in the lower forms of some of the secondary schools the slate has once more come into use. But even a school slate is not to be had for less than several hundred marks and will probably soon cost 1000 marks.

A HOME FOR DRUG TREATMENT IN THE WEST OF ENGLAND.

Bay Mount, Paignton, has recently been opened as a home for the treatment of alcoholism, drug habit, and neurasthenia. The treatment consists in hypodermic injections and a combination of bitter tonics taken by the mouth. The coöperation of a psychologist has been secured for the employment of suggestion in suitable cases. Every case is treated with a view to a permanent cure. Treatment in alcoholic cases takes five or six weeks, in drug cases from six to eight weeks. The drugs are withdrawn gradually and attention is paid to painless cure. Neurasthenic cases of mild type in which insomnia, depression, irritability, and tremors are the main symptoms, require from five to ten weeks' treatment. Both male and female patients are taken and certain male cases can be treated as out-patients. Patients live an ordinary life, and are not under compulsion or restraint. Craving for alcohol is generally lost in five or six days, after which the patient is put on parole, and his promise accepted not to have any alcohol outside the premises. Indoor and outdoor games of all kinds are provided. Medical baths are obtainable at Torquay Spa. The home stands in its own grounds of three and a half acres of secluded gardens, containing a tennis court, croquet lawn, and putting green. The gardens supply the house with all its fruit and vegetables. Paignton is 20 minutes' tram-ride from Torquay, and can be reached by train from London in less than four hours, without a change. The climate is mild, and is remarkable for the amount of winter sunshine. Dr. D. E. Stanford Park is resident medical superintendent.

DEATHS UNDER CHLOROFORM IN CHILDBIRTH.

Two recent inquests emphasise the fact that parturition does not connote the immunity against danger from chloroform administration with which it has sometimes been credited.

The Paddington deputy coroner inquired on Dec. 27th last into the death of a woman of 40 to whom chloroform was being given for an obstetric operation. Death occurred suddenly 20 minutes after induction. Dr. C. T. Parsons, who found some fatty degeneration of the heart, expressed the opinion that more chloroform had been given than the heart could manage.

The City coroner held an inquest on Jan. 16th on the body of a woman, aged 28, who died in hospital whilst under the influence of chloroform given for the removal of a retained placenta. She had been attended at home by two certificated midwives, a nurse, and two doctors, and she reached the hospital in a state of collapse from post-partum hæmorrhage. Chloroform was administered and death took place from asphyxia due to aspiration of fluid from the stomach accelerated by loss of blood whilst under the influence of chloroform. The administrator stated that chloroform had been chosen as an anæsthetic to save time.

At the second inquest, the coroner, Dr. F. J. Waldo, referred to the recommendations made unanimously by the Home Office Committee of 1910 and asked the anæsthetist whether they had been carried out. This Committee, it may be recalled, was appointed to inquire into the question of deaths resulting from the administration of anæsthetics, its members being M. D. Chalmers (chairman), Malcolm Morris, H. A. Shephard, T. A. Bransdon, and W. H. Willcox. The recommendations, nine in number, were put in succession to the witness, who replied as follows to the more important:—

Recommendation 1.—Every death under an anæsthetic should be reported to the corner, who, after inquiry, should determine whether it is desirable to hold an inquest or not. *Carried out?*—No.

Recommendation 3.—No general respirable anæsthetic should be administered by any person who is not a registered medical or dental practitioner. *Carried out?*—No, anyone may still administer chloroform or any other anæsthetic.

Recommendation 8.—In the case of any death under an anæsthetic in a hospital or other similar public institution, there should be a scientific investigation into the actual cause of death conducted by the authorities of the institution. *Carried out?*—No, this has not so far been carried out. The only investigation still made is by a jury before a coroner or by a coroner sitting alone, who sometimes orders a post-mortem examination.

Recommendation 9.—A small standing scientific Committee on Anæsthetics should be instituted under the authority of the Home Office. *Carried out?*—No, not yet.

In summing up, Dr. Waldo called the jury's attention to the meagre results so far following on the Home Office recommendation. No. 3, the most important, had not been carried out. No. 9, the next most important, was eminently fitted for advancing knowledge. The functions of such a committee would be to collect and digest information from all sources, to report on any discovery of new anæsthetics or methods of administration, and to direct chemical, toxicological, or physiological researches to test new discoveries or elucidate doubtful points. Its appointment was a matter which deeply concerned the public at large. Happily, he went on to say, deaths under anæsthetics had been on the decrease from year to year so far as it was possible to judge from the present imperfect system of records. During the preceding calendar year he had only investigated five deaths, the lowest number he could remember. In nearly all the anæsthetic deaths investigated by him during the last 22½ years juries had returned verdicts of death accelerated by chloroform or by a mixture containing chloroform. Deaths were rarely reported to him where ether or gas and oxygen had been given, and he had only inquired into two or three deaths under intraspinal anæsthesia. The status of the anæsthetist nowadays was, Dr. Waldo concluded, on a much higher plane than was formerly the case.

The jury, in returning a verdict of "Death from misadventure," expressed their deep sense of the importance of the issues raised and of the need for further preventive measures.

A WELL-DOCUMENTED METHUSELAH.

To the Editor of THE LANCET.

SIR.—The death of William Kennedy of Holden has been registered with this department. His age is given as 125 years, the primary cause of death being "senility," and the contributory, "exhaustion." On investigating the dates, I got the following information from his son: "He was baptized on Sept. 25th, 1802, near Enniskillen, Ireland, by the Rev. John Richardson, Vicar, parish church of Ireland, and is the son of Thomas and Margaret Kennedy of Glenvannon. I personally copied it from the original in 1898. He had seven brothers and four sisters, and one of the latter was alive two years ago, and was senior to deceased. He shaved without glasses two weeks ago, and until lately could read without glasses. He recited long passages of Scripture within four days of his death, and passed away almost imperceptibly."

Trusting the foregoing information may be of interest to you. I am, Sir, yours faithfully,

DONALD MACKIE,
Deputy Registrar-General.

Bureau of Vital Statistics, Edmonton, Alta,
Jan. 5th, 1923.

IMPERIAL CADET ORGANISATION AND PREVENTIVE MEDICINE.

To the Editor of THE LANCET.

SIR,—In the daily round and common task, it falls to my lot to observe scholars and adolescents from the anthropometric viewpoint. One fact stands out clearly—the evil influence exerted by the Great War on the stamina of the 1905–8 age-groups, 1,600,000 lads. Rickets defect prevails in many children of the later groups. Overcrowding, faulty nutrition, absence of parental control, and State neglect have played their parts in this deplorable business.

Surely the time has arrived for the introduction of an universal cadet system, so that these 1905–8 age-groups may benefit by discipline, games, and ten days' annual holiday camp. In the mother country, Lord Haig's training area organisation, at present in skeleton form, will serve us well, if made incarnate by these lads. The Australasian cadet costume, modified to suit our climate, affords an object lesson in cheap and hygienic clothing. For instructional staff, there already exists ample talent in this country.

Preventive medicine will never come into its own until we attain to a carefully planned routine for the guidance and kindly control of all our youths. The scrapping of the continuation schools renders an all-embracing cadet system imperative and urgent. No new ministries are needed—the machinery is to hand. It rests with the members of our profession to insist upon its being set working, for we possess the confidence and affection of the nation in our exacting and dangerous calling, and our warnings will be heeded.—I am, Sir, yours faithfully,

R. J. E. HANSON,
Surgeon-Captain, R.N.V.R.; Hon. Secretary of the
Imperial Cadet Association.

71, Pall Mall, London, S.W. 1, Jan. 22nd, 1923.

COLONIAL HEALTH REPORTS.

Trinidad and Tobago.—The estimated population of the two islands at Dec. 31st, 1921, was 368,943. The white population is chiefly composed of English, French, Spanish, and Portuguese. The large majority of the inhabitants are natives of the West Indies of African descent, the balance being made up of East Indians, estimated at 128,533, and a small number of Chinese. The birth-rate in 1921 was 31·64 and the death-rate 24·02 per 1000. The number of deaths of children under 1 year of age was 1625. The death-rates from the principal diseases were: diarrhœa and enteritis, 1·61; malaria, 2·42; tuberculosis, 1·34; dysentery, 0·60; enteric fever, 0·65; and ankylostomiasis, 0·81 per 1000. Influenza was prevalent generally and was of mild type. There was no epidemic prevalence of any other disease. Venereal clinics on modern lines have been established in the out-patients' departments of the Colonial hospitals at Port of Spain and San Fernando. On the recommendation of the Central Board of Health drainage schemes for the control of malaria were begun in three country districts, and it is proposed to continue the development of these major anti-malarial measures. The intensive treatment of hookworm disease was continued during the year by the Rockefeller International Board of Health. The Central Board of Health coöperated by enforcing the establishment of latrines in advance of the treatment in the areas about to be operated in. The climate of Trinidad is tropical and may be divided into two distinct seasons: a dry one from January to the middle of May, with an average rainfall of about three inches per month, and a wet one from June to December, with an average of eight inches per month. The coolest months are December to April. The average temperature during the day is 84° and during the night 74°. The climate is healthy and by no means hurtful to Europeans, provided reasonable precautions are taken. Hurricanes are unknown.

Bechuanaland Protectorate, South Africa.—A Census taken in May, 1921, showed that the population then consisted of 150,185 natives, 1743 Europeans, and 1055 Asiatics and coloured persons. The year ended March 31st, 1922, was a mild one so far as the extent of endemic and general diseases was concerned. Of the chief endemic disease, malaria, no special outbreaks, or any of undue severity of type, had to be recorded. This may have been, in part, due to the drought of the previous year, which, for some reason, coincided with good living conditions. An outbreak of whooping-cough, affecting a large proportion of the infant and adolescent population, and accompanied by a high mortality, occurred among the Barolong at Matsiloye, in August. The year showed an increase in the returns of diseases and treatments, as compared with previous years, owing to the continued extension of the medical service which now provides for all the accessible portions of the territory comprised within the principal magistracies. A special feature of this extension has been the establishment of dispensaries for the free treatment of venereal diseases, but the task of bringing these diseases within even measureable distance of control necessarily requires time and patience. The long distances, immemorial customs, ignorance, and superstition tend to retard the work and obscure its issues. The number of patients treated in Protectorate hospitals was 11 Europeans and 66 natives, whilst outdoor treatment was accorded to 10 Europeans and 600 natives—a total of 687, with 13 deaths. The total rainfall in the year ended March 31st, 1922, was 17·100 inches, as against 24·785 inches in the preceding year. The monthly average maximum temperatures at the various magistracies ranged from 72·39° (July) to 93·25° (January) and the minimum 36·66° (July) to 65·59° (January). The Protectorate lies, roughly, between 2000 and 5000 feet above sea-level, and only a few people live at the cooler altitudes of from 4000 to 5000 feet. The portion of the country inhabited by the greater number of both Europeans and natives is adjacent to the only line of railway, which passes through the eastern side of the Protectorate for a distance of 403 miles; the average altitude of the stations and sidings along this section of line is 3418 feet.

PROHIBITION OF WHITE LEAD IN BELGIUM.

A BILL is being prepared by the Belgian Ministry of Labour which will prohibit the sale of white lead under certain conditions, determined in accordance with the conclusions reached at the Third International Labour Conference of the League of Nations. The draft convention adopted at this conference prohibited the use of white lead and sulphate of lead in the internal painting of buildings, with certain exceptions, six years from the date of the closure of the conference. The Municipal Council of Liège has adopted resolutions prohibiting the use of white lead in inside and outside painting work done for the municipality.

FOOD EDUCATION SOCIETY.

WE have received from Viscountess Rhondda an appeal for contributions to enable the Food Education Society, formerly known as the National Food Reform Association, to carry on its educational work in the interest of better diet and hygiene. Owing to shortage of funds there is a real danger that its beneficent activities may have to case. During 1922, over a hundred lectures and demonstrations were given by Miss Florence Petty, who starts the year with some 80 engagements; the continuous sale of literature at meetings, exhibitions, and through the post testifies to the widespread appreciation of the society's efforts. The scheme for helping schools, hospitals, and other institutions by means of periodic visits from cookery and house-keeping experts finds increasing acceptance. Contributions, in the form of subscriptions or donations, may be sent to Mr. Charles E. Hecht, Hon. Secretary, at the office of the society, 329, Vauxhall Bridge-road, London, S.W. 1.

Bandaging Diagrams.—A folder-card drawn up by Mr. J. M. Carvell, M.R.C.S., and published by Messrs. John Bale, Sons, and Danielsson (price 2*d.*), recounts the principles of bandaging and gives some seventy diagrams of bandages applied. It is just the thing to recall to the first-aid student as he travels by 'bus or train the instruction he has been given in his class.

A Lecture

ON

PROGRESSIVE AND MALIGNANT ENDOCARDITIS IN CHILDHOOD.

Delivered at the Children's Hospital, Great Ormond-street, London, on Feb. 1st, 1923,

BY F. JOHN POYNTON, M.D., F.R.C.P. LOND.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

I.—INTRODUCTION.

THOSE of you who have been in these wards for any length of time will have realised the frequency of rheumatic endocarditis in the young, and have doubtless heard me urging you to do more for these children than has been done in the last 20 years. What a splendid opportunity this country has lost of leading the van in such progress! I venture to quote a sentence from a letter to me from Dr. Haven Emerson, of New York, in May of this year, which puts the position clearly. He writes: "Whatever may be the final name or identification of the causative organism (he is writing of rheumatism), we know a plenty to release us for action."

It has released America for action, and to some effect—producing one of the greatest organisations in preventive medicine, the Association for the Prevention and Relief of Heart Disease, of which Dr. Emerson is chief. It is my belief that the fact that rheumatic endocarditis can be produced experimentally with micrococci isolated from rheumatic lesions is, for sufferers from heart disease, the greatest event since Harvey discovered the circulation of the blood. This Association is going to be a living proof of the sanity of that belief, for the view that rheumatic heart disease is infective underlies much of its work.

It can, then, be understood how proud and delighted I was to read this other sentence in his letter. "We owe you and Dr. Paine a lasting debt." This generous tribute from another country contrasts humorously with this sentence from an English review of our work in 1913. "The record of work that they have now put forth will doubtless remain as a valuable landmark in the course of discovery, but time alone will show whether the guide post that they have set up is pointing to the true goal or is only indicative of a side-track." Considerable events have occurred since we first tried to vitalise a scheme here. Vaccine therapy has been born, cancer research instituted, tuberculosis made notifiable, and venereal clinics founded. You can hardly wonder, then, that we dwelt in vain upon the tender age of the sufferers from infective cardiac disease, on the waste of money in adult hospitals upon chronic cardiac cases, on the frequency of cardiac disease in our large towns, and on the tragedy of the damaged struggling in unsuitable employments. Doubtless the problem will be undertaken, and in Liverpool, Bristol, Norwich, and Cardiff steady progress is already being made. London lags behind. I feel that the treatment of scarred hearts by drugs is a threadbare theme. The efficiency of sera and vaccines is not yet successfully elaborated. In the last 15 years I have never seen a case of malignant endocarditis recover under these methods; I have had them under care early, in the middle of their course, and late, and have been assisted by experts, so that I speak with some authority, although my experience may have been exceptionally sad.

You have seen much organic valvular disease in this hospital, but very probably you have not seen a single case of malignant endocarditis such as is found in adult wards. The obvious deduction is that malignant endocarditis is not rheumatic, but when you look deeper than the obvious, you will find yourselves in the midst of most interesting problems.

Is malignant endocarditis, as recognised in adults, rare in children? The answer must I think be, Yes. There are many causes of this fatal disease, some are quite obscure, some are well known, as, for example, the pneumococcal and staphylococcal forms. You also know the view that malignant endocarditis is often due to a secondary infection of previously damaged valves by streptococci. Of the frequency of its streptococcal origin I have no doubt. Has it, however, struck you how many children from five years and onwards are walking about in slums, running about in schools, and living in stuffy rooms with damaged cardiac valves? Children are prone to infections to sore throats, to septic wounds, to bad teeth and unhealthy gums, to adenoids and chronic ear and nose discharges; why, then, is malignant endocarditis, if a secondary infection, so rare? If you have ever cut and examined for yourselves thickened and healed valves you must have recognised the very poor attraction such indigestible tissue must have for micro-organisms. Have you been impressed with the frequency either in adults or children, with which *healed* scars whether of skin or pleuræ or peritoneum, or anywhere else, become septic or become the habitat of micrococci? I have not met with frequent examples of these occurrences.

I think the explanation of the problem of malignant endocarditis is much more complex than this, and I am here bringing forward cases showing how intimately study of the rheumatic infection is associated with that of malignant endocarditis.

I have lately been present at discussions upon a most fatal and comparatively frequent disease, recognised under the name of "subacute infective endocarditis," and have found that in these discussions rheumatic heart disease was ruled out. I confess that I felt disappointed—not because I was thereby debarred from airing my views on rheumatism, but because I believed that, directly or indirectly, light might be thrown on the problems which arise in "subacute infective endocarditis" from the pathology and history of rheumatic heart disease, particularly in the young. Experimentally it is possible to produce with cultures fatal acute rheumatic carditis, simple or malignant endocarditis, pericarditis or fatal dilatation with no peri- or endo-cardial lesions; but we are dealing here with the human side, and it is only necessary to point out that experimental evidence is available.

II.—MALIGNANT ENDOCARDITIS.

The following are illustrative cases.

CASE 1.—A boy, aged 10 years, who, when 9, had been under my observation with a condition which every one here to-day I am convinced would have called acute rheumatism. He developed fever, slight polyarthritis, pain, and active endocarditis, in which both the mitral and aortic valves were damaged, presenting a condition often seen here of mitral and aortic regurgitation. He recovered with these two valves damaged, but a year later again fell a victim to an acute illness with fever and polyarthritis. His heart was dilated, and the previous mitral and aortic disease was still in evidence. The polyarthritis rapidly subsided, but the temperature remained raised and the child was very ill, and now showed the signs of general pericarditis—a disaster seen many times in virulent rheumatism. The pericarditis, however, gradually subsided, but other symptoms now appeared—hæmaturia and enlargement of the spleen with tenderness, increasing fever, and pallor; after 18 weeks' illness death followed. The necropsy showed a healing pericarditis, but malignant aortic and mitral endocarditis. I use the term "malignant" in the unsatisfactory sense it is often used to describe large fungating vegetations, in which were myriads of strepto-diplococci. There were white infarcts in the kidney and spleen.

This case illustrates some of the essential problems of infective heart disease. There are still some who think that rheumatism in childhood is not a special disease, and many more who will not admit that it is a streptococcal infection. Here, then, is a child who had a condition indistinguishable from rheumatism in his first attack, and extremely like rheumatism in his second. I say extremely like, because the polyarthritis recovered and the pericarditis had also commenced to heal, but the endocarditis was progressive and streptococcal.

What was the cause of the endocarditis in the first attack? Was that streptococcal and not rheumatic? Apparently it behaved like a rheumatic endocarditis. What, again, was the cause of the pericarditis and polyarthritis in the second attack? We know from autopsy that the endocarditis was streptococcal—were the other lesions rheumatic? The case clearly shows some of the difficulties in the elucidation of malignant endocarditis, and the dilemma in which those who ignore the rheumatic infection must be placed. I call it a malignant rheumatism with progressive endocarditis, and can see no good reason for assuming that the polyarthritis and pericarditis which subsided were due to any different infection from that of the valves which did not subside. From a study of the morbid anatomy of rheumatic endocarditis I believe that the scars from the first attack were never sound scars, but had always contained within them necrotic areas which harboured the micrococci in a more or less latent phase. Those who served in the late war must have met with some such remarkable occurrence as this during that time: A man who had been severely wounded, and suffered amputation of a limb, came to hospital months later because the healed stump was either so painful, or (perhaps owing to very adverse circumstances of operation) so unsatisfactory that re-amputation or opening of the flaps was necessary. After this operation a virulent septicæmia suddenly developed, causing death. How was this event to be interpreted? We believed that there was latent infection in that stump, and that the opening up of the tissues and the particular phase of the man's resistance was such that the micrococcus became intensely virulent. Such a process I believe to be the basis of many cases of malignant endocarditis in man, for I believe that many adults who appear to have healed valves have unsound scars containing micrococci in a latent stage, and that either a fresh attack of rheumatism or of some other infection, or a lowering of the vitality by insanitary surroundings, by anæmia, or excessive nerve strain and worry, permit them again to become virulent, and, by their peculiar relation to the general circulation, to produce a fatal illness.

The essential point in my argument is, then, that I believe we cannot at present, from clinical observation, tell when a cardiac valve is soundly healed. We shall find in damaged valves small areas of necrotic tissue hemmed round by ill-formed connective tissue, but cannot think that we can detect them clinically in the present state of our knowledge. This is one of my reasons for urging the supervision of rheumatic children, because I hope we may thus discover some evidences of activity of the rheumatic infection which under present conditions we may miss. Supervision of young adults in whom malignant endocarditis is more frequent might very possibly lead us to ascertain much more about the predisposing causes which lead to such a catastrophe.

Assume, now, for the moment, that rheumatic endocarditis is a strepto-diplococcal infection, and that many cases of malignant endocarditis are strepto-diplococcal—I do not say rheumatic. Ought we to picture the resulting endocarditis as due entirely to these micrococci? They are the sparks that start the fire, but how much depends upon the material that is set on fire? That is a problem of great importance, more particularly when dealing with the streptococci, which constitute a group so difficult as to puzzle the most skilled bacteriologist.

It can be seen at once how this question arises in the case I have just described. Was the second illness malignant because the micrococci had been incubating in the child's tissues from the first attack, or because something had occurred to destroy his resistance? Or was it fresh infection in damaged tissues? Or, lastly, had the character of the streptococci altered in some mysterious way in the tissues and ceased to produce rheumatism? Experiment throws just a flash of light upon this question, for we found in a series of animals, inoculated from cultures taken in each case from the damaged valves of the previous animal, an increasing cardiac virulence. It seemed as though their passage through cardiac tissues made them more active in those lesions—but this is only a surmise. We surely may gain some light upon the other side of the question—the influence of injurious surroundings on the character of a cardiac infection—from the supervision of cardiac cases.

Case 2.—A boy, aged 7 years, whose sister had suffered from rheumatic fever and morbus cordis, was admitted to University College Hospital, London, in 1911. He had been suffering from fever, malaise, and polyarthritis on admission, but the polyarthritis had subsided in three days. Then a rheumatic erythema appeared, rapidly followed by endocarditis and pericarditis of extreme severity, with pleurisy. Death occurred after a month's illness. At post-mortem was found a copious blood-stained effusion in the pericardium, with the usual shaggy appearance of the heart. On the aortic valve were minute vegetations which you could have called rheumatic, but from the anterior mitral flap sprang a large recent vegetation, from which Dr. Graham Forbes isolated strepto-diplococci in pure culture, and which resembled the large fungating vegetation of a malignant endocarditis. This specimen, with the cultures and films of the micrococcus, was shown at the Pathological Meeting of the Medical Society of London in February, 1911.

This case again opens up interesting points. Granted that malignant endocarditis is usually an infection, acting in an already damaged valve, we all know this is not a necessity. Pneumococcal endocarditis, for example, is usually fatal in a first malignant attack. Presumably any other cardiac infection may end fatally in a first attack; at least the onus rests with those who claim exceptions to prove this point. Here we have in a child a first attack of streptococcal origin, having associated with it evidences of acute rheumatism—viz., a transient polyarthritis, an erythema multiforme, and a non-suppurative pericarditis, with a condition of the aortic valve not to be distinguished from a rheumatic endocarditis. Was it not probable, then, that the mitral lesion was a primary malignant endocarditis of that valve? If it was, further possibilities arise to which I shall allude later in this lecture.

III.—Progressive Endocarditis.

At this point I am going to turn to mitral stenosis in childhood, reminding you first that the only way to get a complete knowledge of this, the most important of all valvular lesions, is from a study of its origin in the child. At first sight no lesion might appear to be further removed from a malignant endocarditis than this. It is, however, a progressive lesion, for, although it may certainly arrest in an early stage, more often it grumbles on year after year, gradually becoming more apparent on cardiac examination, and then by clinical symptoms. Repeated attacks of chorea, recurrent rheumatic pains, and occasional arthritic swellings may give warning that the rheumatic infection is not dead.

During the early phase over some years there may be no cardiac symptoms, and if the other rheumatic manifestations are absent, one is faced with a primary cardiac rheumatism which may never come under care until the definite clinical symptoms of mitral stenosis have developed. Thus arise many of the cases of mysterious mitral stenosis. I want to emphasise this absence of symptoms in early mitral stenosis, because it is often said, and wonder is expressed, that patients with "subacute infective endocarditis" have had practically no symptoms over long periods. If the infection in these cases is not virulent, but obstinate as it is in mitral stenosis, there is no reason why there should be any symptoms of note. The lesions commence within the valve, the vegetations at first are small, the micrococci liberated into the circulation are neither massive in numbers nor very virulent, and we know that vast numbers of them can be destroyed by the tissues locally. The valve at first is not greatly deformed, and it is only in the later stages when with failing resistance and rising virulence the patient becomes thoroughly ill from toxæmia, or complications, that one can realise the truth.

In passing, I have the greatest objection to the term "subacute infective endocarditis" because it introduces the time element as a criterion of a disease and an infection. Let me add that when I say that vast numbers of micrococci are destroyed locally in malignant endocarditis, I am not making a general statement to fit in with my own views. Years ago at the Clinical Society I saw healed valves shown with large cretaceous vegetations that could only have been at one time a malignant endocarditis. Then in "Researches on Rheumatism" (p. 325), in a paper written 12 years ago, Dr. Paine and I wrote of malignant endocarditis thus: "The point of importance is that in many of the slow cases *there are well-marked attempts at cure in the vegetations*, and if this process is studied we find that the necrotic areas become less filled with clearly staining micrococci and numerous refringent granules become visible." It must not be thought that this disease is progressive in the narrow sense of the word. It is a disease which shows, just as does acute rheumatism, waves of activity and waves of comparative quiescence, but the total result is progressive, there are two steps forward and one back. We want some discovery to tell us how to act when the efforts of nature are causing the step back.

Above all, in considering malignant endocarditis it must be remembered that it is not the size of vegetations but the number and virulence of the micrococci which determine the rapidity of the cases. The rheumatic type usually produces a subacute and chronic form, the pneumococcal a virulent form.

My next case illustrates that a condition apparently so unlike malignant endocarditis as mitral stenosis may terminate as a malignant endocarditis.

CASE 3.—A girl, aged 11 years, had suffered from rheumatism since 5 years of age. I had seen her first at Great Ormond-street, and later at University College Hospital. In all, there had been five definite attacks, and mitral stenosis had resulted, with the usual thrill and presystolic murmur. In October, 1913, she came to my out-patient department at University College Hospital, with a six weeks' history of illness. There had been fever, pains in the limbs and joints, and sweating. On examination I found general pericarditis, but—what was more remarkable—Osler's spots on the pads of the index and ring fingers of the left hand, and a large hæmorrhagic patch in the left palm bordering on the wrist. This case made a great impression on me, for it was the first time I had seen "Osler's spots" in a child, and inquiry from her mother elicited the fact that she had frequently noticed them on one finger or another during the recent illness. The aortic valve was now damaged as well as the mitral. This child lived for 14 weeks with continuous pyrexia, and at the end of October had a cerebral embolism in the left middle cerebral artery. The necropsy showed numerous subserous petechiæ, infarcts in the spleen and kidneys, and a small aneurysm on the left middle cerebral artery. There was stenosis of the mitral, with a large vegetation on the anterior flap which had spread to the aortic valve and also on to the wall of the left auricle. Strepto-diplococci were obtained in pure culture from the vegetations.

I have seen other examples in childhood of the supervention of malignant endocarditis upon a mitral stenosis, and the particular interest of such cases to me lies in the probability that the valve at the time of the fatal illness was never thoroughly healed. The spread of endocarditis from the mitral to the aortic valve, so frequent in the young, suggests a threatening malignancy, and we have shown that later in life such cases may become malignant.

IV.—SIMPLE ENDOCARDITIS.

My next case is very recent; the diagnosis when the child left the hospital was not that of malignant endocarditis, but the case illustrates certain features in acute rheumatism which help us to realise how closely rheumatic carditis and malignant endocarditis may approach one another.

CASE 4.—A boy, aged 11, was in the hospital six months, and came under my care on Feb. 18th, 1922. He had been ill for two months before admission, beginning on Dec. 2nd, 1921, with a chill followed by a sore throat and weakness. The sore throat was said to have been a "quinsy which did not break." In January, 1922, he had pains all over him, and some pleurisy, and recently there had been another sore throat. On admission he had a large heart with a mitral systolic murmur. The liver extended 1½ inches below the costal arch, and both pulmonary bases were impaired. The diagnosis of rheumatic heart disease was made, and four days later pericarditis was detected. A fortnight later the friction had almost disappeared, and both the *aortic* and the *mitral valves* were now found to be damaged. A week later he had another sore throat, more fever, and some arthritis of the right shoulder. At the end of March nodules were appearing on the knuckles and elbows. In April he had another sore throat and fever, and in May another, the fifth since his first illness, with rheumatic arthritis in the left shoulder. Blood cultures were sterile, and neither salicylates nor vaccines appeared to influence the disease. In June and July he began to improve slowly, and we hoped that he would in spite of an aortic and mitral lesion with a badly damaged myocardium be able to undergo an operation for enucleation of the tonsils, which we had by force of circumstances been compelled to treat temporarily by local painting with iodine. Once more at the end of July, just as arrangements had been made, there was another sixth attack of tonsillitis, with arthritic pains, fever, cardiac dilatation, and epistaxis. A recurrence of pericardial friction was also detected. The parents now removed him from hospital.

This case was an unfortunate one. It was apparent that the pressing need was enucleation of the tonsils, but the first attack of carditis was so serious and the damage so extensive that I confess to have been afraid to expose the boy to the risk, with recent aortic and mitral lesions and a heart weakened by pericarditis. Each time we seemed to be getting him sufficiently well, he relapsed, and finally his parents preferred Christian Science, which may succeed if his tonsils make a final and successful effort.

These relapses have been well recognised in acute rheumatism; in fact, the late Dr. J. MacClagan believed the cause of rheumatism to be akin to malaria for this very reason. They are seen repeatedly on a minor scale, and from our point of view they are of interest, because they point to waves of virulence and periods of latency in the infection, and it is on this feature I have been dwelling with reference to malignant endocarditis. It is very difficult to separate such an illness from a malignant endocarditis, and had there not been the incessant sore throats it would have been still more difficult. If this patient survives, as he may do with a sadly damaged heart, he is just the case I should suspect might die later developing a frank malignant endocarditis.

This completes my illustrative cases: the first was a malignant endocarditis in a child with damaged valves; the second a primary malignant endocarditis attacking a previously healthy valve; the third a malignant endocarditis supervening upon an active mitral stenosis; the fourth a recurrent rheumatic carditis, approaching closely to a malignant type.

V.—CONCLUSIONS.

Malignant endocarditis in childhood shows the same features as in the adult, though as a rule it is more rapid in its course. There are fever, sweating, anæmia, purpura, Osler's spots, infarctions, optic neuritis and retinal hæmorrhage, drowsiness, aneurysms, diarrhœa, cerebral hæmorrhage or embolism, hæmaturia, enlargement of the spleen, cardiac bruits, and a continual excited action of the heart. I have seen in a child a femoral aneurysm as large as a cocoanut from an embolus in that vessel. This likeness to the adult cases is most significant when the close association with acute rheumatism is seen.

I hold that there is a rheumatic malignant endocarditis which may arise from the simple form or be primary in origin. Further, I believe that the mysterious cases of streptococcal origin in adults are either primary cardiac rheumatism of a malignant type or, if not actually rheumatic, more closely allied to the rheumatic infection than any other. In other words, they are due to a strain of that group, just as we get different strains in other great infections—e.g., typhoidal, pneumococcal, and meningococcal.

I hope, then, that these cases have illustrated my main thesis—namely, that a study of rheumatic heart disease is probably one of the best methods available at present for throwing light upon the malignant endocarditis met with not only in childhood, but also adult life. But it is not my wish to give the impression that I can only see malignant endocarditis in childhood through the spectacles of rheumatism. On the contrary, I have seen fatal cases associated with osteomyelitis of staphylococcal origin, and complicated with numerous metastatic abscesses; I have also seen them result from pneumococcal infection, and associated with pneumonia.

Naturally it will be asked why malignant endocarditis is rare in the child and rheumatic heart disease so common; to answer would require a much more profound knowledge of disease than I possess, but I believe it to be bound up with the problem of the differences between immature and mature tissues. The great infections in childhood tend either to be overcome, or to generalise and kill by wide dissemination—general tuberculosis, general rheumatism, general pneumococcal infection. In the adult the tendency is to local virulence—pulmonary tuberculosis, virulent pneumonia, malignant endocarditis. It may be that with the supervention of puberty some mysterious changes occur in the tissues that cause the streptococci which produce acute rheumatism in the young to alter their behaviour and produce the more obstinate lesions of the malignant type of endocarditis, but this is mere speculation, and I incline to the streptococci having a prolonged life in human tissues and to diminished resistance of these tissues.

VI.—Primary Cardiac Infection.

I will now dwell shortly on primary infection of the heart, meaning by this an infection attacking the heart so predominantly that any invasion of other tissues either does not occur, or is so slight as to be overlooked. For a tuberculous child to have a predominant meningitis is no rare event, and when it occurs we do not say it is not tuberculous because there is no other obvious sign of that disease. Again, chorea frequently occurs as a *solitary* manifestation, and we do not say it is not rheumatic on that account, because we realise that some years later the child may be seen with an obvious rheumatic polyarthritis and heart disease. It has taken many observers and many years to prove this latter fact. We are at present in much the same position with rheumatic heart disease, and it is continually stated that a case of endocarditis is not rheumatic because there is no history of rheumatism. Why should not many of these cases, nevertheless, be rheumatic in the sense that they are due to the same infective agent, only that in these instances the other manifestations have been suppressed or have been so evanescent as not to attract attention? We can only settle this point, as chorea was settled, by a great number of observations by many observers. If there is a primary cardiac rheumatism, why should it not conform to other great infections and be of all grades of severity from fulminating malignancy—through subacute forms—to the simple progressive mitral stenosis? There seems to be no reason to the contrary, and it would be surprising if rheumatic endocarditis was always simple in character.

In conclusion, I can see no reason to suppose that there is any mysterious hidden disease "rheumatism," existing apart from any manifestations—a curious idea prevalent, I believe, in this country—a disease which has no manifestations except those produced by a *secondary* invasion by streptococci. It is a pure assumption, which might be equally applied to the tubercle bacillus and tuberculosis. That in both instances there may be a constitutional tendency no one would deny, but the day is passed when we call tendencies diseases, and the day has not yet come when experimental evidence, showing that the essential lesions of a disease (the lesions which indeed constitute the disease as we know it) can be reproduced by micrococci, is to be put aside, and the manifestations of a disease are to be looked upon only as secondary results due to an added causal factor. If we are to find that there is a disease rheumatism bereft of carditis, polyarthritis, nodules, chorea, and so on, and when these occur are to call them complications, we are faced, in my opinion, with a new pathology of extreme complexity.

THE IMMEDIATE MICROSCOPIC DIAGNOSIS OF TUMOURS

AT THE TIME OF OPERATION.

By ERNEST H. SHAW, M.R.C.P. Lond.,
DIRECTOR OF CLINICAL PATHOLOGY AND PATHOLOGIST, ROYAL NORTHERN HOSPITAL; CONSULTING PATHOLOGIST, HORNSEY COTTAGE HOSPITAL.

It is now 12 years since I ventured to draw the attention of the medical profession to the value of the immediate microscopic diagnosis of tumours at the time of operation.[1] After an experience of the practice of the method which now extends over a period of 23 years, I have no hesitation in again urging its great value, in the hope of making its use more widely known and more appreciated.

The method of examination which I practise and for which I claim great advantages, is very simple and is given in detail at the end of this paper. The whole process, including freezing, cutting, mounting, staining, and examining of a section, can be accomplished, when the pathologist is well acquainted with histology and morbid anatomy, in the short space of five minutes or less. It will be seen, therefore, that the delay in the performance of an operation is very short and is amply compensated for by the information gained as to the exact nature of the tumour with which the surgeon has to deal. The accurate diagnosis of a tumour cannot always be made from clinical evidence alone, and the aid of the microscope is often required. In some parts of the body such as the mouth, nose, cervix, and skin, a piece of the suspicious lesion can be removed without a general anæsthetic and sections prepared by the slow paraffin method. In other situations, particularly the breast, a general anæsthetic is required in order that the surgeon may make an exploratory incision.

Operative Problems.

It is often found, and one may say it is generally the case, that when the tumour is exposed the naked-eye appearance makes the diagnosis fairly easy; but this is not always the experience of operators. What happens? In some cases the surgeon explores a swelling and finds a mass of tissue which is not obviously new growth. A close inspection and palpation are not sufficient to enable him to decide whether he is dealing with a malignant growth or an inflammatory mass. Say the lesion is in the breast, what is the surgeon to do under these circumstances? If the lump is malignant the extensive operation of amputation of the whole breast with removal of pectoral muscles and axillary glands is indicated, whereas a simple inflammatory condition of the breast requires but a simple local removal. The muscles and axilla need not be interfered with. I think all surgeons will agree that this is not an uncommon problem. In these cases the presence of a pathologist who possesses the requisite knowledge of morbid anatomy and histology, with his simple cutting apparatus, is of great service to the surgeon. In the absence of a pathologist a surgeon has to make up his mind to do one of three things: (1) remove a small piece of tissue for subsequent microscopic examination and close the wound; (2) remove the mass or breast locally; (3) amputate the whole breast and remove muscles and axillary glands. If the tissue or lump after subsequent microscopic examination proves to be malignant, a second operation must then be undertaken. This means anæsthetising again a patient who has suffered great mental anxiety while awaiting the pathologist's report. I have had many specimens sent to me for examination and report from cases falling in these divisions which have proved to be malignant. An immediate microscopic section at the first operation would have enabled the surgeon to settle the diagnosis straight away. An important point in such cases is the risk to the patient of the dissemination of malignant cells during the interval between the first and second operations after opening up the surrounding lymphatics by the surgeon's knife. This appears to be a real danger which I think all will admit. I have not had the opportunity of proving this by an actual example and should be greatly interested to hear whether any surgeon has met with such a case in practice.

---

[1] The Lancet, 1910, ii., 939.

Supposing the surgeon decides that the operation indicated under procedure (3) is the one to perform, and this is carried out. If the tumour proves to be malignant the operation is quite justified; on the other hand, if a careful examination of the specimen reveals the absence of a malignant growth an unnecessarily severe operation has been performed. I have examined many breasts removed in this manner for supposed malignant disease which showed only inflammatory changes and cysts. I think it is a great pity such mistakes should occur.

Illustrative Cases.

The following cases will serve to support my view that an immediate microscopic examination is of real value to the surgeon:—

A typical example of breast tumour of doubtful clinical nature; the patient under the care of Mr. Tom Bates; I was asked to attend the operation. A small tumour was felt in the breast, whether solid or cystic it was not possible to tell. An incision revealed a small solid hard mass, about three quarters of an inch in diameter. A fresh microscopic section showed spheroidal-celled carcinoma with well-formed fibrous matrix. The complete operation was performed, and the breast when removed was found to contain, in addition to the above growth, a large thin-walled simple cyst. There was one small soft gland in the axillary fat; this gland was found to be free from secondary growth.

The following two cases under the care of Sir Crisp English are instructive:—

In both patients a small firm freely movable tumour was felt; provisional clinical diagnosis, fibro-adenomata. In the first case the growth was excised and found to be well defined, flat, nodular, and about ¾ by ½ in. in its chief diameters. On section it was hard, white, and contained several minute cysts. A fresh microscopic section revealed the typical structure of columnar-celled carcinoma. After complete removal the breast was found riddled with small cysts and several large soft inflamed glands were seen in the axillary fat. A definite instance of carcinoma arising in part of a chronically inflamed breast. The tumour in the second case was very similar in size and appearance to the above. It proved to be a simple fibro-adenoma of the acinous variety and so no further operative steps were necessary.

The next case shows in a striking manner the value of obtaining immediate microscopic evidence of the true nature of a breast affection.

Clinically there was a retracted nipple with puckering of the adjacent skin, and below this a firm mass was felt. The surgeon had no doubt that the lesion was malignant, and made a few facetious remarks on meeting me at the patient's house. I was present at the request of the doctor in charge of the patient. However, the pathologist often gets his own back, and histological evidence was obtained in a short time as to the true nature of the trouble. The mass was simple inflammatory in character, carcinoma and tubercle were easily excluded. A small operation was then performed.

The following interesting case occurred a short time ago in the practice of Mr. Sampson Handley.

Several small nodules were present just beneath and apparently attached to the skin over the breast. The nodules suggested secondary deposits from a growth in the breast, but no tumour could be detected by palpation of that organ. The nodules were removed and examined at once. The microscope revealed small atheromatous and calcareous arteries, with much small round-celled infiltration of the walls and surrounding tissues, and an organising thrombus in one of the vessels. No evidence of new growth could be discovered and so nothing further was done.

The presence of atheromatous arteries in this situation is very interesting and quite new to me.

Cysts of the Breast.

Cystic changes in the breast are very common and in nearly all cases multiple. Clinically they are very often difficult to make out, for a small deep-seated cyst may form a hard swelling and fluctuation may be absent. The difficulty of deciding this point is proved by a reference to my tables of cases. Of 382 cases of breast swellings 113 proved to be cystic. The advantage gained by having fresh sections prepared and examined in such cases is strikingly shown by observing the number of breasts in which carcinoma was found at an early stage. From experience gained by observation I make it a rule carefully to examine the wall and adjoining tissues by cutting up the breast in thin slices and then preparing sections of the hardest part. In this way I have been able to detect early formation of carcinoma in eight cases. The new growth is usually found in the inflamed breast tissue outside the cyst wall, but sometimes the latter is involved. These results are sufficient to discourage the practice of tapping breast cysts and letting the person go away without further operation; if this is done one can never tell when a carcinomatous growth is missed and given a fresh lease of life. The fluid removed from these cysts gives no indication of the presence of carcinoma. Discussing this procedure some years ago with a well-known surgeon who practised it, I was told that one of his cases did return later, and that he discovered carcinoma in the wall of the cyst tapped some months previously.

Duct papilloma usually leads to bleeding into the cyst, and so the withdrawal of fluid by tapping is not likely to be followed by the departure of a patient without further interference. In the instances mentioned above where carcinoma was found in or outside the cyst wall, no bleeding had occurred and the fluid contents were either dark and clear or milky in appearance.

Frequent Occurrence of Multiple Cysts.

Although in some breasts there is apparently one cyst only, if one slices through the organ in nearly all cases other small cysts are to be found. A common condition is multiple cysts ranging in size from about 1¾ inches to ¼ inch in diameter. Between the cysts the breast tissue is usually hard or "knotty," and microscopic examination of these patches sometimes reveals the presence of carcinoma. The question arises in the case of a cystic breast as to how much of the organ should be removed. The general cystic breast must, of course, be taken away entirely—i.e., dissected from beneath the skin, the latter with the nipple being left behind—it is not necessary to remove any skin, and as women value the nipple it should also be left. Where there is apparently only one cyst, and the breast tissue around looks natural, a local removal may be undertaken, but, as I have pointed out above, there is every possibility of there being other cysts present in other parts of the breast; if these are left behind further trouble is to be expected, for they may enlarge and necessitate a further operation, and are also potential sites for the development of carcinoma. I would therefore feel inclined to advocate the complete enucleation of the gland as for the definite multiple cyst cases. This may seem a drastic policy to pursue, and it is often disregarded, but one always feels rather anxious as to the future development when it is neglected. This, however, is a point worthy of a full discussion by surgeons and pathologists; so many matters in the personal and mental conditions of patients have to be taken into consideration, and surgeons are divided in opinion on the subject.

The above examples will, I hope, serve to support my claim that the immediate microscopic method is of real value—by this method a correct diagnosis can be made at the time of operation, and thus supported the surgeon can pursue the right line of treatment with feelings of the greatest confidence. This method of investigation should also appeal to the general practitioners, who from the nature of their work are frequently called upon to treat early cases. I have dealt rather fully with breast problems for two main reasons, first because they so well illustrate the difficulties of diagnosis, and secondly because they form such a large proportion of the cases I have had to deal with in my practice. During the past 23 years

I have attended as pathologist to assist the surgeon in making a diagnosis in 540 cases, and a reference to the list appended will show that of this number 382 were clinically doubtful tumours of the breast.

I may, perhaps, be permitted to observe that these cases have occurred in the practice of a large number of surgeons, most of whom are well known. This is a striking commentary on the difficulty and occasional impossibility experienced by able surgeons in making a correct diagnosis at times on clinical evidence alone, and a sufficient proof that the method advocated here is sound in principle.

Selection of Piece of Tissue.

This very important point needs careful attention by the surgeon and pathologist. Such an observation may seem superfluous, but in my experience it is not always easy to determine whether the incision into a buried mass has quite reached the tumour proper. This is especially marked in breast tumours when a small nodule of carcinoma is surrounded with dense inflammatory tissue. I have had to ask for a second piece to be cut out in such cases when the first piece examined has shown a structure inflammatory in nature and yet not quite like ordinary mastitis. A case I saw lately illustrates this point very well—a large fatty breast with a growth buried in the deeper part, the nodule being about three quarters of an inch in diameter. An incision was made and passed through the side of the growth, the lateral portions retracted at once and the surrounding breast tissue bulged into the wound, completely hiding the real tumour. The effusion of blood which goes on at the same moment increases the difficulty of distinguishing the different tissues properly, and if the operator is not extremely careful a piece of the bulging tissue is removed and the growth itself missed. The first piece removed was taken from the "bulging" tissue and a second piece lower down showed the structure of carcinoma. A pathologist thoroughly familiar with the naked-eye appearances of morbid tissue can make a shrewd guess on carefully "blotting" the piece removed as to whether the right tissue has been given him for examination. In all cases of growth or ulceration the periphery or edge should be selected for examination, and care should be taken to include a portion of the normal tissue. It is particularly important to follow these precautions in tongue lesions and ulceration of the cervix. In growths of the jaws and other bones any part of the tumour will usually suffice.

Mouth.—In this region it is often easy to cut out a piece at the edge of a suspicious ulcer or swelling while the patient is in one's consulting room. I have often done this myself. In other cases this is not possible or advisable; the presence of a pathologist in the operating room is then of great assistance to the surgeon. So much inflammatory thickening occurs about growths in the mouth that a small piece may not include a portion of the tumour, and a mistake in diagnosis is easily made. This point must be borne in mind by the surgeon who sometimes snips or peels off a tiny piece of the edge of an ulcer for purposes of examination. I recorded an instance in my previous paper illustrating this. The advantages gained by the presence of a pathologist at the operation are—failing a definite report on the first piece examined other and larger pieces may be cut out if the clinical condition warrants a further investigation. The following case is of interest:—

Papillomatous growths were present in the cheek and lip of a man, and another on the tongue. Several glands were felt in the neck. The growths from the cheek and lip were examined and found to be innocent papillomata. A piece from the tongue lesion showed early carcinoma developing in the deeper part. Mr. Sampson Handley then removed half the tongue and cleared out the glands. The latter were free from secondary growth.

In another patient a small ulcer was present on the inside of the cheek. Its nature was doubtful and a small piece was removed for examination. A fresh section showed inflammatory changes and so nothing further was done.

Jaw.—The following jaw cases may be recorded:—

A growth involved the right upper jaw of a girl aged 15 years. A small piece examined at the time of operation showed typical sarcoma of the spindle-celled variety with also some myeloid cells and spicules of bone. Mr. E. B. Waggett then removed the superior maxilla.

A female patient under the care of Mr. W. D. Harmer had a suspicious lesion of the maxillary antrum. Microscopic examination of the tissue scraped out showed simple inflammatory changes and two small myxomatous poylpi. No further operation was needed.

A young man developed a swelling in the symphysis of the lower jaw, a piece of the growth which was solid and white showed the structure of squamous-celled carcinoma which had evidently originated from the deeper part of the gum. Mr. Harold Wilson removed the symphysis and cleared out the lymphatic glands below the jaw. These glands did not reveal any growth on subsequent examination of paraffin sections.

Larynx.—The uncertainty in making a definite diagnosis from pieces of growth removed from the larynx is well known, and is due to the difficulty of removing a wedge of growth through the glottis, particularly in the cases of papillomatous masses on the vocal cords. Where investigation of the lesion necessitates thyrotomy the preparation of a section is of great value. I have recorded cases illustrating this in my previous paper.

Gall-bladder.—The following case shows in a striking manner the value of coöperation between the surgeon and pathologist. It occurred in the practice of my late chief, Mr. C. B. Lockwood.

The patient had symptoms of gall-bladder trouble and an exploratory operation was contemplated. Before going on with this, however, the surgeon removed a piece of tissue from a small swelling over one of the lower ribs, and microscopic sections were prepared. These showed the structure of columnar-celled carcinoma. The diagnosis was then made of primary carcinoma of the gall-bladder with a secondary deposit in the chest wall. An advanced case, obviously unsuitable for any further interference.

Uterus.—In uterine cases frozen sections can be prepared from material removed with the curette and from pieces cut out of the cervix; an immediate diagnosis made, and if malignant a radical operation performed forthwith. Under certain circumstances, for domestic or personal reasons, it is a great boon to the patient to have the diagnosis settled immediately and for the operation to proceed under the one anæsthetic. In cervical growths at an early stage several pieces can be examined, the smaller and earlier the growth the more risk one runs of missing the important spot when one piece only is removed at a preliminary sitting. The soft material obtained from the body of the uterus is not easy to preserve in thin slices, but with practice it can be done.

In the list of cases which accompany this article it will be seen that carcinoma was demonstrated in 5 cases out of 15 curetted. Fortunately for the pathologist carcinomatous tissue hangs together sufficiently well to enable him to proceed with the necessary manipulations required to mount and stain the sections. Wedge-shaped pieces removed from the cervix are easily examined. Out of 8 cases I found carcinoma in 7.

In a patient operated upon by Dr. Cuthbert Lockyer, soft friable fragments were curetted from the body of the uterus and fresh sections showed the structure of columnar-celled carcinoma. In another patient Mr. Lockwood curetted tissue from the interior of the cervix, which proved to be columnar-celled carcinoma. My note describes the specimen after removal as a large, soft, white and hæmorrhagic growth in the upper part of the cervix, and many large fibroids were present in the wall.

I was present at an operation by Mr. Percy Furnival on a patient whose uterus had been removed some months previously for carcinoma of the cervix, and in whom some growth had apparently recurred, as several small nodules were discovered in the scar at the upper end of the vagina. The patient wished for the operation to be carried out in her own house, and it was decided to have microscopic sections examined at the time of the operation. The little nodules were removed, and the sections prepared and microscoped at once. They showed the structure of simple granulation tissue. The granulations evidently arose as the result of irritation around the stitches put in at the former operation. The innocent nature of the lesion having been proved no further interference by the surgeon was necessary, and the anxiety of the patient and relatives was thus allayed.

Vagina.—Primary carcinoma of the vagina is an uncommon condition and the following case is worth recording :—

A small soft red mass projected into the lumen from the lower end of the vaginal wall, it was circular in outline and had not invaded the adjacent tissues. The late Sir Charles Ryall removed a piece of the growth and microscopic examination revealed the structure of squamous-celled carcinoma. A wide local removal of the tumour was then performed.

Foot.—The following case may be quoted.

Mr. Sampson Handley removed a piece from the edge of a growth occurring in the skin of the sole of the foot. An immediate microscopic section showed the structure of a papilloma. As so often happens is such growths, a part of this tumour looked suspiciously like carcinoma in an early stage, but one came to the conclusion that it was as yet in the simple condition. A local removal only was therefore performed.

In another patient under the care of Mr. L. E. Barrington-Ward a soft fungating mass was present on the inside of the left foot. A small piece of the tissue was examined microscopically which showed the structure of a spindle-celled sarcoma, so amputation of the limb was proceeded with at once.

I find that some surgeons consider frozen sections of fresh tissues unreliable and difficult to "spot." I take this opportunity of pointing out that this is incorrect. The sections prepared in a few minutes will be found to show the structure of tumours and tissues quite as plainly as those cut and stained by the paraffin method. The mechanical processes involved in freezing, cutting, mounting, and staining of fresh sections are very simple and may be acquired by anyone after a little practice. The interpretation of the pictures presented under the powers of a microscope, however, is a different matter ; here the pathologist is put on his mettle.

Evolution of Pathology.

Just as a surgeon himself requires years of experience for the successful practice of his craft, so it is necessary in the case of a pathologist. The latter must investigate every kind of morbid lesion and of normal tissues, so that by familiarity with their naked-eye and microscopic appearances he is able to make up his mind quickly and act. He must be able to give a definite opinion as to whether the case he is dealing with is malignant or not. The surgeon expects a quick and definite report, on which the fate of an important organ of the body, or even a limb, often depends. I have made it a rule to have paraffin sections prepared of all my cases, and am pleased to be able to record that in every instance the pictures seen in the permanent sections have agreed exactly with those made immediately at the operation—surely a striking proof of the reliability of this method.

In a few instances I have not been able to place a growth in its exact group—i.e., carcinoma or sarcoma —but in none of them has there been difficulty in stating whether the lesion was malignant or innocent. In one case of stomach ulcer the fresh section showed simple inflammatory changes, and this was verified by the paraffin section. Later the clinical condition progressed in a malignant manner. The explanation of this failure to spot malignant growth microscopically is the fact that carcinoma arising in chronic ulcers of the stomach does not at first involve the whole edge. Therefore the piece removed may easily come from an innocent part. This case proves that it is not safe to rely on a section from one part of an ulcer, and is a vindication of the present-day practice of complete excision of gastric ulcers whenever possible.

Many years ago morbid anatomy formed the whole bulk of the science of pathology, which was greatly helped and put on a sound footing by the introduction of histological methods. Thirty years ago the pathological work at my old hospital consisted of the examination of post-mortem and operation material by the surgical and medical registrars. Microscopic sections were made by clerks, and submitted to the registrars, who duly reported on them. All sections were prepared by the freezing method after preliminary hardening in alcohol or Müller's fluid. Bacteriology then came along with rapid strides and the post of pathologist was instituted. Since that time specialisation has taken place to an advanced degree, and now we have the bacteriologist, morbid anatomist, clinical pathologist, chemical pathologist, and so on. This evolution in pathology appears to have had the effect of limiting the extensive study of morbid anatomy and histology to quite a small number of pathologists.

The acquisition of a wide knowledge of tumours and diseased tissues both to the naked eye and under the microscope requires long and constant observation of a mass of material such as can be acquired in the post-mortem room, museum, and pathological department of a large hospital. To this must be added a sound knowledge of clinical medicine and surgery. Embryology also plays an important part in helping one to elucidate the mystery of some tumours. A complete knowledge of all the above branches of pathology is obviously not within the reach of one man, but for the work advocated in this paper I wish to advise the morbid anatomist of the future to follow the line set out above. He will be well repaid by the great pleasure given him by the interesting pictures seen on the table and under the microscope.

I have seen the statement made that "there is nothing fresh to be seen in morbid anatomy and histology." I do not envy the man who made that remark. My own experience in the study of morbid anatomy began in 1884 at St. Bartholomew's Hospital Museum, and morbid histology in 1892. Since that time it has continued at Cambridge, two other London hospitals, most of the London hospital museums, and the institution to which I am now attached. Yet rarely a week goes by in which I do not come across something new to me—surely a sufficient answer to such a foolish statement.

Pathological Report During Operation.

In some instances my services have been retained under rather peculiar circumstances. The patient has heard that a pathological report could be obtained during the course of an operation, and has asked for this to be done. It has occurred to me that a wider knowledge of the method under review among general practitioners and the public will have the effect of inducing patients to consult their doctors at an early stage of malignant disease in greater numbers than at present occurs. No doubt the general public has been largely educated to realise the importance of early diagnosis, and doctors are consulted early much more commonly now than was the case 20 years ago. But one still occasionally sees a breast containing a large mass of carcinoma which is ulcerating, and sometimes actually fungating through the skin. I think the delay in such cases is mainly due to the fact that many women look upon the loss of a breast with feelings almost of horror, and put off a visit to their medical attendant as long as possible. If women could be induced to seek advice directly they notice a lump in the breast the mortality from cancer would be greatly reduced. They could be assured that only in the event of an adverse verdict by the pathologist would a big operation be performed. Again, in view of the known facts that cancer arises in the great majority of cases in a breast already altered by inflammatory action, the small operation of local removal would prevent the formation of cancer in a great many women by getting rid of the precancerous focus.

I feel sure, therefore, that prompt and accurate diagnosis by means of the microscope may be a valuable and powerful agent in the fight against cancer.

From this standpoint, in early and doubtful cases, the surgeon is able to take up a firm and reasonable attitude which must have considerable weight with patients in inducing them to submit to early treatment, save them a great deal of anxiety and distress, and incidentally reduce the incidence and mortality of cancer.

Suggestion for a National Pathological Museum.

I should like to add a few words in favour of a scheme which has been in my mind for many years—viz., the establishment of a national pathological museum, to contain examples of every disease of which examples can be obtained, especially microscopic sections of the different tissues. All specimens should be fully described and accompanied by clinical histories, so that pathologists might turn to them for guidance in every instance where they come across a tumour which is new to them, and thus be enabled to place it in its proper group and give a prognosis. At present a pathologist is often unable to give precise information as to what course the case showing an unusual type of tumour is likely to take. Sometimes he can get this information from a brother pathologist, who happens to have met with a similar case, but very often he cannot do this. Then, again, pathologists often hold different views as to the nature of certain tumours and their probable course—i.e.,. malignant or innocent. Definite information on these points would therefore be obtainable in the records attached to the specimens in the proposed museum. The most important part in such a museum would be taken by microscopic sections; photographs or drawings should accompany each specimen, and a complete index should be made to facilitate rapid reference—something on the same lines as the "finger-print" records department of Scotland Yard. The museum could also be extended so as to include all varieties of bacteria. Such a museum would be analogous to the national collection of type cultures recently inaugurated by the Medical Research Council at the Lister Institute.

I am fully conscious of the difficulties to be surmounted in its formation, the main difficulty being that of finance, but it ought to be done. The investigation of the nature and cause of cancer would be helped enormously by the creation of such a storehouse of valuable material and information. In my own experience I often come across a section which does not fall into the routine groups, and after a period of puzzling and uncertainty I manage to recognise it by comparison with a similar specimen in my collection. At other times the nebulous picture of a similar specimen seen years before will not materialise and I am left helpless. I have then to do the best under the circumstances. In yet another case the microscopic structure of a tumour appears quite new to me. How helpful and comforting it would be to compare the section with others in the proposed National Museum! The above sketchy and disjointed remarks will, I hope, serve to draw attention to the project which I have so often thought about. It would take many years to build up such a structure, but the Museum of the Royal College of Surgeons of England would form a splendid nucleus.

Tabular List of Cases: Explanatory Note.

A note of explanation is necessary in several of the headings in the list of cases which follows.

Under mastitis are placed 41 cases entered in my earlier records as simply mastitis. Some of the specimens were indurated patches of breast tissue with no gross cysts, others contained tiny cysts visible to the naked eye. I had not realised at that time, or at any rate, had not considered it worth noting, that almost all breasts affected with chronic mastitis contain cysts ranging from a microscopic size to an inch or two in diameter. Cysts with papillomata projecting into the cavity, but not filling it, are separated from those cases in which the growths formed a compact mass entirely filling the cyst. In such specimens the tumour is often apparently a solid growth not definitely separable from carcinoma to the naked eye. In some of the cases of chronic abscess *Staphylococcus aureus* was isolated by cultivation. The two cases of lipoma occurred in the fat over the axillary tail of the breast and simulated breast tumours. The encysted remains of a silk ligature appeared as a nodule in the skin scar after removal of the breast for carcinoma.

Method of Cutting Frozen Section of Fresh Tissues.

The method may be divided into two parts.

1. *Arrangement of Apparatus.*—The microtome is placed on a firm table and all the instruments arranged in a convenient manner. A mental survey of the freezing, cutting, mounting, and staining of a section is then made to ensure that everything is present and in its proper place and that no time will be wasted when once the process is begun.

2. *Preparation of Microscopic Section.*—

(*a*) The selected piece of tissue received from the surgeon is placed on the disc of the freezing microtome and is surrounded with gum solution.

(*b*) The tissue and gum are frozen and sections made by a razor on a carrier.

(*c*) The sections are transferred to a dish of cold water, and after separating them with a glass rod a suitable section is lifted out.

(*d*) The section is dipped for a moment into pure methylated spirit.

(*e*) The section is placed into another larger dish of cold water, and the currents set up by the spirit in the water cause the section to spread out flat.

(*f*) A glass slide is dipped in the water under the section, and the latter is lifted out as the slide is slowly drawn up out of the water again.

(*g*) The water is drained off the slide and a few drops of diluted stain (Löffler's methylene-blue, about 25 per cent.) are allowed to fall directly on to the section.

(*h*) A thin cover-glass is placed on the stain and section after several seconds; it is lightly pressed down so as to drive out excess of stain and flatten the section; the stain is blotted off, and the specimen is ready for examination under the microscope.

The above method is essentially the same as that which I originated in 1899. Two alterations were made some years ago: (1) Substitution of the ethyl chloride spray for the old ether apparatus—by this means a piece of tissue may be frozen on any flat piece of roughened glass, metal, or even wood; and (2) diluted stain instead of the full strength, which acted too quickly and gave very dense pictures.

Quite a small table will do to arrange the various instruments on, and this should be placed opposite a window if possible. I have had to fix up my apparatus in all kinds of odd places, such as the landing at the top of a flight of stairs, a board placed across an ordinary bath, the corner of an operating room, a rickety table in a small cottage, on a bed, &c. Most often one can commandeer a bedroom after the patient has been taken out to the operating room. Sunlight from a window is the best, but sometimes one has to trap a beam from an overhead lamp. A paraffin lamp in a house far away in the country caused me the greatest trouble. I have recently seen a new form of illumination in which an electric bulb is fitted to the substage reflector of the microscope; the current is supplied by a small portable battery. This ought to be very convenient. All my apparatus, including a folding microscope, is carried in a small bag.

THE CAUSES OF DEATH IN CHRONIC VALVULAR DISEASE OF THE HEART.

BY JOHN COWAN, M.D., D.SC. GLASG.,
PHYSICIAN, ROYAL INFIRMARY, GLASGOW;
AND
J. K. RENNIE, *M.C.*, M.B., CH.B. GLASG.,
DISPENSARY PHYSICIAN, ROYAL INFIRMARY.

THERE is a curious paucity of information with regard to the immediate causes of death in chronic valvular disease of the heart. We have been unable to find any literature upon the point, though the lesions themselves, their physical signs, their degree, and their complications are discussed in detail in innumerable papers. Allusion is made to the conditions which may induce failure: the activity of some new factor, in the heart itself or in some other organ, producing a disturbance of the cardiac action; the effects of acute inflammation of the valves or pericardium; the results of failure of the general or the cardiac nutrition; the influence of an abnormal rhythm of the heart, excessive exertion, renal disease, mental shocks, &c.; but no figures are given to indicate the relative importance of the various factors. But, if our prognosis is to be even approximately accurate and our treatment rational, the relative importance of these factors must be known, so that we may devote our attention to those which are most common, and by preventing or delaying their onset, postpone indefinitely the advent of the end.

This paper is an attempt to throw some light upon the problem. We had at first intended to collect a large number of clinical records, but a little consideration showed us that such an investigation would be useless on account of the difficulty, in chronic valvular disease, of recognising the presence of a fresh subacute endocarditis. We have, in consequence, examined those records alone which were followed by a post-mortem examination. The series thus numbers only 100, but it was collected in one set of wards by the same observers. In these 100 cases valvular disease of some kind was found to be present upon post-mortem examination. In 19 cases the valvular lesions were purely acute, while in 81 they were, in part at any rate, chronic (see table).

Cases of chronic valvular disease without acute endocarditis, 42.

Pure Acute Endocarditis.

The first group of cases of acute endocarditis may be briefly reviewed. Four patients were suffering from chorea, and two from acute rheumatism, the endocarditis being merely a part of a general infection. In two cases it was a complication of pneumonia. In one it was a part of a general sepsis, occurring post partum in a woman suffering from phthisis. In eight cases it arose insidiously, associated in three cases with a pulmonary catarrh, and in one following closely upon an attack of encephalitis lethargica. In two cases no useful history was available. There remain for consideration 81 cases, all of which showed a chronic valvular lesion of some description.

Chronic Valvular Disease.

In 39 of the 81 cases of chronic valvular disease an *acute* or *subacute* endocarditis was found to be also present. In one case no history of the fatal illness was available. In the other cases the onset of symptoms was more or less abrupt in 13, and insidious in 25. In the first group the endocarditis followed acute pneumonia in two patients. In one, a woman aged 56, the earliest symptom was a "shock," due to embolism, on the morning of the day on which she died. In one, a man aged 37, the first symptoms were noticed one morning when he rose from bed, and, rapidly becoming extreme, led to his death five weeks later. Symptoms followed attacks of acute rheumatism in seven patients, arthritis of obscure origin in one, and the extraction of a carious tooth in the last. In the second group the onset of symptoms was insidious and progressive.

The association of acute endocarditis with such acute infections as pneumonia and post-partum sepsis is, of course, well known, but it is apt to be forgotten that it may follow sepsis in almost any organ of the body. In this series the fatal illness was probably due, in individual cases, to infection from a very offensive atrophic rhinitis, an otitis media, tonsillar infections, cholecystitis, a chronic gastric ulcer, a chronic dermatitis, and pulmonary and uterine infections. In one case a cancerous ulcer of the stomach, a tuberculous focus in the lung, and sepsis in the urinary tracts, offered a choice. It is, too, worthy of note that only nine of these 39 cases showed organs that were not affected by pathological lesions quite independent of those which were the results of the cardiac disease. The vast majority, of course, showed sepsis in the tonsils and around the teeth.

The immediate cause of death in acute endocarditis is very varied. In some cases the endocarditis is merely a part of a general infection. In others infarcts may cause death. In the majority, however, the cause of death is cardiac failure on account of the associated myocarditis. The frequency of cerebral lesions in acute endocarditis seems to have been underestimated. In the whole series, 19 cases of pure acute endocarditis and 39 cases of acute endocarditis engrafted upon a chronic valvular lesion, 58 in all, 13 cases showed gross cerebral disease, softening in 6, meningitis in 4, hæmorrhage in 3.

Chronic Valvular Disease Without Acute Endocarditis.

There remain for consideration 42 cases of chronic valvular disease in which acute endocarditis was *not* present. In two cases the history of the fatal illness was imperfect, and the cause of failure unknown. One patient, a man, aged 62, had been suffering from shortness of breath upon exertion for many months. The aortic valve was incompetent, the pericardium adherent, the lungs emphysematous, and the kidneys fibroid. The other, a man, aged 42, had disease of the aortic and mitral valves and fibroid kidneys. On admission into hospital he did not appear to be seriously ill, but acute œdema of the lungs ensued shortly afterwards, and he died within two hours. In six cases death occurred as the result of causes other than cardiac. One patient died from acute meningitis associated with a cerebral abscess, the sequel of a chronic otitis media. One died during an attack of acute rheumatism, one from purpura hæmorrhagica, one in uræmia, the result of an exacerbation of a chronic nephritis of seven years' standing; two died from pneumonia, associated in one case with aortic disease and phthisis, and in the other, a mitral case, with gonorrhœa

Eleven patients dated the commencement of their cardiac symptoms to some definite extrinsic cause. A patient with aortic disease stated that he had never been well since an attack of influenza. Another aortic patient, an alcoholic who had suffered from syphilis and had made a good recovery from an hepatic abscess, suffered from his first symptoms after a cold; and a mitral patient gave a similar story. A mitral patient died from cardiac failure which followed a prolonged attack of vomiting due to a duodenal ulcer. An aortic patient stated that his cardiac symptoms arose after he had sustained a compound fracture of his leg. A mitral patient dated the onset of symptoms to her second attack of rheumatism two years prior to her admission to hospital, while her distress had been greatly aggravated by dancing for many hours one evening. Another patient was never well after her last confinement four years previously, the symptoms being exaggerated by heavy work necessitated by a drunken spree of her husband. A mitral case, of 20 years' standing, ascribed the onset of her symptoms to starvation and overwork. An aortic case broke down after a skating party; a mitral case after one severe exertion. The last case illustrates the strain which is thrown upon the heart by acute bronchitis. The patient, a foreman with a firm of horse dealers, took a shipload of horses to Canada for sale. On Sept. 21st he ran the horses in the show ring without distress. On the voyage home bad weather was encountered and his cabin was flooded on Sept. 27th. Bronchitis ensued, and *two days later his legs became œdematous.* On his admission into hospital cardiac failure was extreme, but though he improved considerably he never regained his health, and died a year later.

In the remaining cases, 23 in number, it is evident that for some time before the fatal illness some symptoms of cardiac insufficiency had been present, though they were not sufficiently severe to incommode the patient greatly. In 13 cases pulmonary symptoms were urgent at the end. Infarcts were found in the lungs in five cases, accompanied in one by pneumonia, and in another by gangrene. Bronchitis was present in eight cases, in two of which pneumonia preceded the end. But most of these patients had multiple lesions in the other organs. The pericardium was adherent in four patients, and acutely inflamed in another. The kidneys were fibroid in six cases, and showed infarcts in one more. One patient had a cirrhotic liver, one a tuberculous tumour of the colon, another suffered from paralysis agitans. In no instance was the heart the only damaged organ in the body. In four patients a "shock" was the first symptom of importance, the result of hæmorrhage in one case, and of embolism in two. In the fourth, where the left arm became suddenly weak while the patient was walking on the street seven weeks before her death, and another shock occurred six weeks later, no gross lesion of the brain was discovered at autopsy, the brain being rather small and notably œdematous. In four cases, two mitral and two aortic, death ensued after a progressive cardiac failure for which no particular cause could be found. In three of these patients infarcts were present in the lungs. In the other pericarditis occurred before death, and the kidneys proved to be fibroid.

Paroxysmal Tachycardia.

The incidence of disturbance of the cardiac rhythm was rather striking, 21 of our cases showing this phenomenon in some form. In one case death ensued as the result of recurring attacks of paroxysmal tachycardia.

The patient was a labourer, aged 38, who had aortic valvular disease, probably of syphilitic origin, an atheromatous aorta, renal calculi, and cirrhotic kidneys. His earliest complaint was of attacks of palpitation, which at first were generally nocturnal. They occurred about once a week and lasted for an hour or two. But as time went on they became more frequent and of longer duration, and he became short of breath upon exertion, and so weak that he was forced to take to bed. When first seen he was very ill, in full orthopnœa with laboured cyclic respirations. His pulse was shotty and regular and numbered 88. In ten days improvement was distinct and he was able to lie down in bed, breathing easily. But four days later an attack supervened, the pulse numbering 152–180. It lasted for eight hours, and all his old distress at once recurred. Some improvement followed, but not so great as after the first attack. A few days later another attack occurred, and, though it only lasted for an hour, greatly intensified his discomfort. In the evening another attack supervened, the pulse running about 200. The cyanosis became extreme, the dyspnœa urgent, and after three hours his heart ceased to beat.

We have seen several other cases of this description.

A married woman, aged 27, who had a mitral lesion of rheumatic origin, dated the commencement of her cardiac symptoms to attacks of palpitation. The attacks recurred, œdema made its appearance, and she was forced after some months to take to bed. On admission into hospital the lungs were congested and the feet œdematous, and the urine contained much albumin. The pulse was small and weak, quite regular and numbered 80. A short paroxysm a few days after admission, though it only lasted five minutes, greatly intensified her distress. Two days later another paroxysm ensued, the pulse running about 150–170. The breathing was frequent, and at short intervals attacks of intense breathlessness occurred, lasting for several minutes and notably increasing her discomfort. After a few hours the pulse became imperceptible, the extremities cold, and the urinary output less. She died suddenly after the attack had lasted for 56 hours.

Another patient, aged 53, had a mitral lesion and chronic bronchitis. She contracted an acute bronchitis and her cough became very troublesome and accompanied by vomiting, so severe as to interfere with her nutrition. When first seen she was very weak and ill, the countenance livid and congested, the extremities œdematous, the liver large and tender, the abdomen swollen with ascites, and the urine loaded with albumin. She had to sit bolt upright in bed. The pulse was small and feeble and numbered about 200. The paroxysm passed off, and she made some improvement, the vomiting ceasing and the pulse running about the normal rate and improving in quality. But the attacks of cough recurred, the face becoming enormously swollen and extremely livid during their continuance, while the jugular veins dilated to many times their normal size. The pulse became tiny and uncountable and very frequent, but it resumed its former characters as soon as the cough ceased. A few days later it was noticed that the tachycardia after an attack of coughing continued and her discomforts were not relieved. In the night the normal rhythm returned and for the first time a few extrasystoles were recorded. But the respite was short, for next day the tachycardia returned, the pulse numbering about 230 ; her weakness steadily increased and she died after the tachycardia had lasted for 47 hours.

The mechanism of cardiac failure in these cases is clearly revealed by graphic methods. In the majority, at any rate, of these cases the new rate of the pulse is due to the inception of a new *rhythm*, the stimuli arising in the vicinity of the auriculo-ventricular node instead of at the sino-auricular node, and exciting the auricles and ventricles to contraction simultaneously instead of in sequence. As the ventricle is in contraction at the time of the auricular contraction, and the auriculo-ventricular valves are in consequence shut, the ventricular output is lessened, and the pulse loses in volume and in force. The auricular contractions, too, can only drive the blood backwards into the veins instead of forwards into the ventricles ; venous stasis is thus initiated, which, if the paroxysm is of long duration, rapidly becomes serious, the lungs and liver becoming engorged and œdema making its appearance in the feet. It must also be borne in mind that a similar state of affairs occurs whenever the pulse-rate rises to 150 or over, even though the rhythm is unaltered, for at this rate diastole is so short that auricular systole occurs *before* the preceding ventricular contraction has ceased, and stasis in consequence ensues. We do not yet know the exact causes of paroxysmal tachycardia. The sudden commencement and cessation of the attacks suggests a nervous, or a functional, cause. But it seems probable that some underlying myocardial lesion in the vicinity of the auriculo-ventricular node makes this area hypersensitive to nervous influences. A comparable auriculo-ventricular rhythm, *nodal rhythm*, has been found to be associated with acute inflammatory lesions in these parts, but the altered rhythm in these cases is continuous and not paroxysmal.

Many patients suffer from paroxysmal tachycardia for many years without serious result if their hearts are clinically structurally sound. But the onset of attacks in patients with hearts already strained by valvular disease, particularly if the muscle is also involved, adds greatly to the danger. The complication, however, is by no means constant.

Heart-Block.

In one case death ensued in a patient who had full heart-block. Heart-block, however, is not necessarily accompanied by symptoms of cardiac failure, though their occurrence is the rule. It is generally the result of a myocardial lesion which happens to hit the auriculo-ventricular bundle. In the majority of these patients the myocardium generally is severely damaged, but this is by no means necessary, and if the lesion is small the heart may be able to do its work reasonably well even for years. Sir William Gairdner, for example, had complete heart-block for at least four years before his death, during which time he was able to live fairly comfortably without any signs of cardiac failure. One of W. T. Ritchie's patients lived for ten years. But in the majority of these patients a widespread myocardial lesion is present, and death ensues rapidly on account of the extent of the muscular damage. Heart-block, of itself, does not interfere with the cardiac work to any measure comparable with the interference produced by paroxysmal tachycardia.

The striking phenomena of disturbance of the cardiac rhythm have perhaps led us to attach too much importance to this condition as a cause of cardiac failure. In nodal rhythm, of course, whether paroxysmal or continuous, the onset of failure may be very abrupt as the direct sequel of the change of rhythm, and the consequent simultaneous contraction of auricles and ventricles. In heart-block and in extra-systole a synchronous contraction of these chambers may also occur, but only occasionally, and the forward progress of the blood is but little hindered. Heart-block, as we have seen, is not necessarily accompanied by grave cardiac failure. Extra-systoles have no evil significance. In auricular fibrillation the cardiac work is always hindered, for, as the auricular contractions are in abeyance, the normal filling of the ventricles is incomplete, while their contraction, irrespective of their content, leads rapidly to arterial anæmia. The nervous control, too, is in abeyance, and the ventricular activities are no longer accurately correlated to the needs of the tissues. But even in fibrillation the cardiac work may be accomplished without much difficulty and one of our patients, a miner, worked at the pit-head for six of the nine years that his auricles were fibrillating. In auricular flutter evidences of cardiac insufficiency soon make their appearance if the ventricular contractions are frequent, but may be absent if, as is sometimes the case, the ventricular rate is about normal.

In this series of 42 cases disturbance of the cardiac rhythm was not infrequent. Full heart-block and paroxysmal nodal rhythm were present in one case each, extra-systoles were recorded in four, and auricular fibrillation in 15. But in another 15 cases the records show that the rhythm throughout was perfectly normal. In six more no irregularities are noted. It is also clear that in some cases the disturbance of rhythm is merely a by-product of a widespread myocardial lesion, which in itself is producing serious failure. The relationship may be clear from clinical observation alone, and may sometimes be inferred from post-mortem findings.

Alteration in Heart Muscle.

The most important cause of cardiac failure is that due to alterations in the muscle of the heart. One is apt to forget that the condition of the systemic muscles is repeated in the muscle of the heart, and that the flabby muscle of the legs which prevents exercise is associated with a cardiac muscle of like nature. Granular and fatty changes, atrophy and fibrosis, occur in the heart, as elsewhere, from general and local causes. They may be due to anæmia of local or of general origin ; infections, whether local or general ; local and general intoxications. Of all possible causes those which affect the cardiac valves and the cardiac arteries are those which affect most constantly and in greatest degree the cardiac muscle, but general causes invariably produce some local result.

The figures which we submit correspond with our theory. Of these 81 cases of chronic valvular disease the cause of failure was in two cases unknown. In six cases death ensued from causes quite distinct from the cardiac disease. In 11 cases cardiac failure followed the activity of factors outwith the heart. Of the other 62 cases, in 49 the heart itself seemed to be the prime factor in the failure, and *in 39 of these an acute endocarditis was present at death.* The commonest cause of cardiac failure in chronic valvular disease seems thus to be an acute re-infection of the cardiac valves. Acute endocarditis is most common in rheumatic patients, and least common in syphilitic patients. Of our 58 cases of acute endocarditis, 19 purely acute and 39 associated with chronic lesions, 32 were rheumatic and only one syphilitic. One patient had suffered from both diseases. The immediate cause of death in cases of chronic valvular disease is varied. In some a general sepsis is present, in some embolic lesions in the organs occasion death, in some the valvular fault progresses beyond the point where compensation can be effected. But in probably the majority the cause of death is muscular weakness from the associated myocarditis. If subsequent investigations prove that our conclusions are correct, which we have no reason to doubt, the treatment of chronic valvular disease must be greatly altered.

It is manifestly necessary to restrict physical exertion in cases of acute endocarditis during the progress of the acute infection, as well as in those chronic cases in which symptoms of cardiac failure are already manifest. But our figures show that in chronic valvular disease death usually occurs as a result of the activity of factors arising without the heart, of which over-exertion is the least common and infection the most common. So, if we are to obtain the maximum success in the treatment of our patients, we must encourage them to the utmost activity that their cardiac disability permits, and endeavour in every way to keep them fit. The details of the process will necessarily vary, but if the principle is accepted the detail is easy to envisage and to pursue in the individual case.

The second indication is to eradicate as rapidly and as efficiently as possible every source of sepsis in the individual. A wide outlook is necessary, for the sources of sepsis are numerous and varied. Mouth, throat, nose, ears, gastro-intestinal tract, bladder, uterus, gall-bladder, urinary tracts, must all be examined, and any infection radically treated. And if success follows our endeavours our patients will lead more happy, more healthy, and longer lives.

OBSERVATIONS UPON CARDIAC RHEUMATISM OF CHILDHOOD.

By MARTIN O. RAVEN, M.B., Ch.B. Oxf., M.R.C.S. Eng.,
MEDICAL OFFICER OF HORSFALL WARDS, BROADSTAIRS.

The following notes relate to 24 cases which have during the last 14 months received treatment, in a seaside medical ward, for rheumatic disease of childhood, with reference to the condition of their hearts. The view taken of rheumatism has been that it is a chronic infection, comparable to tuberculosis, attacks of arthritis and chorea being merely symptoms of the underlying disease, and the scheme of treatment has accordingly been based on the assumption that where there have been recent symptoms of active disease, it will take time, rest, and fresh air to effect a cure.

The cases are divided into four classes: 1. Those showing damage to the heart so extensive as to make the survival of the patient impossible or extremely problematical (five cases). 2. Those showing signs of endocarditis, but in which there is every hope that an active life may result (four cases). 3. Those in which the damage to the heart has been slight, and the endocardium spared, and in which, if the infection is cured, a normal individual should result (eight cases). 4. Those who have had rheumatism, but no signs of heart disease (seven cases).

The average stay of the cases has been four and a half months, the actual periods of treatment varying from a few weeks to 14 months (treatment uncompleted).

1. *Extensive Damage to the Heart.*

Of this class, one case was removed and was lost sight of; two died within two months of admission with all the symptoms of heart failure, following upon extreme myocardial disease and multiple endocardial lesions, and with pyrexia and intense anæmia. Both had had quite inadequate rest, following on repeated attacks of arthritis, previous to admission. The other two cases are still under observation, having been kept continuously at rest for 12 and 8 months respectively. On admission each had anæmia and symptoms of heart failure, following upon repeated attacks of arthritis. The first child had aortic regurgitation, and, with mitral regurgitation and mitral stenosis (presystolic murmur), hypertrophy and dilatation of the right heart; the pulse was between 130 and 140. The second child had an enormous heart from hypertrophy, following upon chronic adhesive pericarditis, together with signs of mitral endocarditis; the right auricle was very greatly dilated, and the heart beat tumultuously and always over 120. As a result of practically continuous recumbency, both cases have made excellent progress. The damage to their hearts is, of course, permanent, but the anæmia has disappeared, and the pulses, though very excitable, are often counted at about 84. The improvement is such that one would be tempted to hope that the rheumatic infection had been stamped out, but for the fact that during the last two months each child has had an acute pyrexial attack, taking the form in the first case of an acute tonsillitis, and of præcordial pain in the second, making it seem probable that further attacks of rheumatic origin —tonsillitis and pericarditis—have occurred. In spite, therefore, of the benefit accruing from prolonged treatment, the latent existence of the original infection must still be suspected, and beyond this there is still the question of the ultimate capacity of these damaged hearts to support lives sufficiently active to be useful.

It is obvious that, were there adequate provision for the treatment of every case of early rheumatic infection, hearts of this type would not be met with, but until the disease is made notifiable, and institutions are provided for their observation and treatment, there seems no possibility of control of rheumatic heart disease. I may also remark here that, in contrast with tuberculosis and syphilis, where bacteriological examination and serological tests give great assistance both in diagnosis and control of treatment, there is no known laboratory method by which the virulence of rheumatic infection, or even its existence, may be gauged, and we are entirely dependent upon clinical symptoms and signs, the correct interpretation of which is by no means certain. This general position indicates the great need for bacteriological and serological research in rheumatic disease; a laboratory devoted to examination of rheumatic patients from a pathological aspect would have no lack of material to draw upon.

2. *Endocarditis with Hope of Active Life.*

These cases are perhaps the most interesting. They all four presented on admission signs of damage to the mitral valve, as indicated by a diastolic bruit audible at a point just internal to the apex of the heart, and usually heard just before the second sound: this murmur probably indicates the presence of an active, quiescent, or healed vegetation on the mitral valve, and I have seen it develop into a proper presystolic murmur of mitral stenosis in the case of a boy who was insufficiently rested for a period of 12 months following the original attack. The most important fact about this diastolic bruit is that if the patient is put to rest early enough and for long enough, it may disappear altogether. This has happened in three of the four cases I am describing here. All these were admitted with anæmia, slight pyrexia, rapid, excitable pulses, and cardiac dilatation; all had mitral regurgitant murmurs also; one had chorea.

The disappearance of the diastolic bruit took place slowly (in one case it took six months), and with its disappearance, the rapid pulse became normal, the anæmia vanished, and in one case the heart shows to-day no abnormal signs at all. The other two cases, though apparently quite well in other respects, have a hypertrophied heart and a systolic murmur respectively. In the fourth case, still under recumbent treatment, the diastolic murmur is quite unchanged. Whether the disappearance of this bruit indicates that the mitral valve is now quite normal only time can show. Mitral stenosis is a progressive lesion, and we come across many people later in life whose hearts show presystolic murmurs and who have had no symptoms for years while the valve must have been narrowing.

3. *Slight Damage, without Endocarditis.*

Into this class I have put those cardiac cases showing no evidence of endocarditis. Several of them, however, had dilatation of the heart, probably indicating recent rheumatic myocarditis, and most of them had the systolic murmur of mitral regurgitation. With complete rest for from four to eight months, these murmurs have completely disappeared in three out of eight cases, and the signs of cardiac dilatation have decreased. A variation in the cardiac dullness from day to day is an important sign that more rest is required, or that a child is being allowed to get up too soon.

4. *Rheumatism with No Signs of Heart Disease.*

These cases were those who had had in the past attacks of arthritis, but whose hearts were quite normal on examination. Some had had chorea. They were kept at rest for a fortnight, and then allowed to live a quiet life under observation for six weeks or more, and were then allowed to return home. One hopes that in these cases even a short fresh-air existence may have obviated the likelihood of further attacks of the disease.

Treatment.

Recumbency, fresh air, and warmth have been the chief aims. The worst cases have been kept strictly recumbent against bed-rests for from 8 to 14 months: the others have been allowed to get up little by little, as the symptoms subsided, beginning at a quarter of an hour a day and working up gradually to a full day before discharge; then they have always been sent back to the hospital or physician that sent them for further observation.

Prognosis.

It is difficult, in view of the obscurity of the ætiology of the disease, and the absence of laboratory aid, to determine the existence or virulence of infection in any given case. The clinical indications are many, but some are uncertain in their import. A *normal temperature*, for instance, is no indication that infection is stamped out: possibly the rectal temperature, as has been suggested, would be more useful, but it has not hitherto been practicable. *Chorea* also is a most uncertain symptom: well described as a nervous symptom in a rheumatic child, it is no indication of the virulence of the infection. This statement is borne out by the case of a child who had made excellent progress from the point of view of the heart; her chorea was quite in abeyance, when, on being visited by an anxious mother one day, all her choreic movements returned; not only this, but three children in adjacent beds acquired the symptoms also for a few days. But the progress made by the heart was quite unchanged throughout the attack.

The chief indications of definite improvement with regard to the combating of the infection seem to be, first, the disappearance of the anæmia, and secondly, the alteration in the abnormal signs of the heart. Of the latter, I would like again to lay stress especially on three: (i.) Rapidity and excitability of the apex beat and pulse; (ii.) the diastolic bruit above referred to; (iii.) cardiac dullness, especially when varying from day to day, or on a slight additional degree of bodily exertion.

Conclusion.

Although the number of children under observation has been small, there can be no doubt, from the progress they have made, of the desirability of prolonged recumbency in every case of cardiac rheumatism, and that the earlier this treatment is initiated, the less prolonged it is likely to have to be. Compared with a policy of physical and emotional rest, fresh air, and warmth, such influences as climate cannot be taken into much account; similarly, treatment by drugs, useful though they undoubtedly are—particularly salicylates, digitalis, and opium in appropriate cases—is properly regarded only as accessory to a general management on these lines. But in the case of poor folk, at least, this policy can only be attempted if institutions are devoted to the observation and treatment of the disease; and rheumatic carditis, owing to its insidious mode of onset, will never be prevented from permanently undermining the health of children, unless it is by means of notification brought under the eyes of responsible medical officers in its early stages.

Clinical and Laboratory Notes.

A NOTE ON
ANTHRAX INFECTION BY SHAVING BRUSHES.

By F. A. KNOTT, M.D. LOND., D.P.H.,

DIRECTOR OF THE LABORATORIES, CLINICAL RESEARCH ASSOCIATION.

RECENTLY, whilst I was examining a shaving brush which belonged to a sailor who, shortly after rejoining his ship, had developed a typical anthrax pustule, a possible fallacy came to my notice. The man had bought and used the brush while on leave, and its hairs contained virulent anthrax bacilli. A number of brushes from the same manufacturing source were tested, with negative results in all, yet no other likely source of infection could be discovered. Did the brush infect the patient, or did the patient on the last occasion of shaving infect the brush? As far as I know, the point was never fully cleared up. The *free* hairs of his brush gave a strong growth of anthrax, whereas those *embedded* in the handle were sterile. It is commonly held, in such circumstances, that the brush was probably infected *after* manufacture, and it is officially advised that only by examination of the stump hairs is reliable indication of the manufacturers' use of infected hair obtained.

Nevertheless this inconclusive case prompted a brief experiment. By melting the fixative out of the handles of a considerable number of cheaper shaving brushes bought at random in London, one was able to determine its melting point. In most instances a temperature of 145° C. was reached before this substance was sufficiently fluid to be of the least use in resetting the hairs in the handle. The required level was never lower than 130° C.

To test the point more fully, I set out, with the assistance of Mr. J. McLean, to deal with a number of experimental brushes by the following method:—

(*a*) To take the place of the handle the lower 1½ inches of a common glass test-tube was cut off and sterilised. Into ten of these, fixative taken from actual brushes was placed and just melted (140° C.) on a hot plate. Previously a series of short bundles of autoclaved shaving-brush hairs had been heavily infected at the lower ends with a thick suspension of living anthrax spores. These bundles of hair were thrust into the just molten fixative in the test-tubes, the tubes immediately removed from the hot plate, and the fixative allowed to set. Next morning these experimental "brushes" were broken up and the stumps incubated in nutrient broth. In no case did *B. anthracis* develop. A control "brush" was made, agar being used instead of fixative; from this anthrax developed next day quite readily.

(*b*) A number of actual brushes, from which the fixative had been completely melted out and the stump hairs loosened as far as possible, were next autoclaved and placed, base upwards, in a rack. The bottom of the handles having been removed, on to the lower ends of stump hairs so exposed 0·1 c.cm. of a suspension of resistant anthrax spores was dropped, and allowed to remain three minutes. Fixative (temperature 140° C.) just liquefied was next run into each handle, enveloping the base hairs and coming up to that level actually adopted by the manufacturers. These brushes were allowed to stand over night, and next day the stumps were aseptically broken up, extracted, and incubated at 37° C. in broth. At the end of 72 hours in no case had anthrax developed.

The only conclusion to be drawn is that the process of fixing the stump hairs of these brushes with a hot glue-like substance often effectively sterilises the portions of hair so fixed. If the fixative has a sufficiently high melting point, say 140° C., to resist boiling water, any bacteria or spores present in the hair before manufacture will frequently not appear in cultures made from the stump. If anthrax or other organisms *do* develop from these embedded stumps one can safely assume that they were originally present in the hair. But when the stumps remain sterile one cannot apparently conclude that the hairs were sterile in their original state—i.e., before manufacture of the brush.

The observation is made since an idea appears to be prevalent that the correct way to examine a shaving brush bacteriologically is to seek for anthrax in the stump. The presence of the organism in this site is admittedly almost conclusive evidence of the manufacturer's use of infected hair, but where the stump does not contain anthrax, and the free hairs do, it cannot with equal certainty be assumed that the hair originally employed was not anthrax-infected.

A CASE OF EXTRA-UTERINE PREGNANCY.

By A. McMurray, F.R.C.S. Edin.,
HONORARY ASSISTANT SURGEON, CHESTER ROYAL INFIRMARY.

The following is a rather unusual case of extra-uterine pregnancy:—

The patient was seen in the morning by Dr. A. Leigh, in consultation with Dr. G. A. Paulin, of Malpas, and was operated on by Mr. C. Dobie at the Royal Infirmary, Chester, the same afternoon. She had had previous pregnancies, and the present pregnancy was of about eight months. At the third month she had a slight show, otherwise during the whole eight months she enjoyed excellent health. The evening before she had felt the fœtal movements more marked, with pain in the right side. During the night pain was more acute and she felt very faint. At operation an almost full-term child was found floating about in an abdomen full of blood. The placenta was well confined to the right broad ligament. The membranes were extremely thin and only adherent in one small spot to the omentum. The uterus was the size of a two and a half months' pregnancy. Both mother and child died.

It is somewhat exceptional for a woman who does heavy household work to progress to full term without showing any symptoms or signs.

A CASE OF
RETROPERITONEAL FIBROMA
ARISING FROM THE ANTERIOR COMMON LIGAMENT.

By W. H. Ogilvie, M.Ch. Oxf., F.R.C.S. Eng.

The interest in the following case is in the rarity of the condition. The presence in a woman of 55 of a large mass in the abdomen, quite fixed and of almost stony hardness, made malignant disease the only reasonable diagnosis. On the other hand, there was no point in the history, symptoms, or pre-operative findings, to indicate the organ involved. Operation was undertaken purely for purposes of exploration.

The patient, a thin married woman, looking more than her age of 55 years, came up to surgical out-patients complaining of a throbbing sensation in the upper abdomen, which she had noticed for three months. This was the only thing of which she complained. There had been no vomiting, loss of weight, or pain, nor had she noticed any lump. All her bodily functions were normal.

Condition on Examination.—A prominence was immediately visible, occupying the left upper quadrant of the abdomen. This proved on palpation to be a hard solid mass oughly oval in shape, firmly fixed to the posterior abdominal wall. It reached inwards to the mid-line, downwards 2 inches below the umbilicus, while above it appeared to pass under the costal margin. It formed no prominence in the loin, did not move on respiration, and could not be moved passively. On percussion, the splenic dullness appeared to be continued into that of the lump; over the most prominent part there was a band of resonance. Urine normal; fæces gave a weak guaiac reaction, but no blood spectrum; Wassermann reaction strongly positive. X ray examination showed the stomach displaced downwards and outwards by a large mass in the region of the lesser omentum, suggesting a pancreatic cyst.

Operation.—Laparotomy (May 25th, 1922) through a left paramedian incision. The stomach, splenic flexure, and descending colon were seen to be carried forward on a large retroperitoneal mass, over whose summit ran the inferior mesenteric vein. The left kidney could be felt behind the upper pole of the swelling. An incision was made outside the descending colon, and the peritoneum and vessels displaced inwards as far as the aorta. A smooth, oval tumour, 2½ by 4 inches, was thus exposed, surrounded by a distinct capsule, and firmly attached to the bodies of the second and third lumbar vertebræ. Three of the lumbar arteries entered the mass, and the aorta was pushed slightly to the right. The lumbar arteries were ligatured at their origin, the tumour separated by the knife from the anterior common ligament from which it appeared to spring, and shelled fairly easily from its capsule. The wound was sewn up, a drain being left in the extraperitoneal tissues for 48 hours. Microscopic section showed the tumour to be a fibroma, with much necrosis.

Recovery was uneventful, the patient leaving the hospital perfectly well.

I am indebted to Mr. R. P. Rowlands for permission to publish this case.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Late Results of Encephalitis Lethargica.

The meeting of the section for the Study of Disease in Children of the Royal Society of Medicine, held on Jan. 26th, was devoted to a discussion of the late results in sleeping sickness, with an exhibition of cases illustrating various features of the disease. Dr. **Eric Pritchard**, the President of the section, occupied the chair.

Demonstration of Cases.

Dr. **R. C. Jewesbury** showed two cases. The first patient, aged 4 years, was normal to the end of his first year. Then he had an illness which was accompanied by a progressive weakness of limbs, and he became unable to sit up unassisted, or even to hold up his head. Three months after the illness began he was brought to hospital, and his temperature ranged between 104° and 105° F. He had marked hypotonia, tendon reflexes were absent, and there was slight internal strabismus. He developed tetany of the hands. The cerebro-spinal fluid appeared normal, and the Wassermann was negative. There remained a marked spasticity of limbs, he could neither sit up by himself nor stand, the reflexes were all exaggerated, and the plantar response on both sides was extensor. His mentality was very clear. The other patient, a girl, aged 10, was thought to have had an attack of meningitis in 1918, and after it she lost power in the limbs, and was unable to speak for five months. She was left with a very definite incoördination, and at the time of her illness the muscular tone was increased. When seen by the exhibitor there was but little unusual in the nervous system to be made out. The chief sequel was ataxy, which was still very pronounced; she also had tremor of the intention type. Though until her illness she was bright, she was now mentally backward, and was attending a special school.

Dr. **H. C. Cameron** showed three cases, and referred to a brother of one of them who had no after-effects. In one of his cases the first idea was that the illness was botulism, but later it was recognised as sleeping sickness. The case was now spastic and mentally backward. Other two cases had made a fair recovery, but when the hands were held out they behaved like those of a case of chorea. At night they had a restless phase and at times there were bouts of noisy breathing, with flushed face and cheeks puffed out.

Dr. **F. J. Poynton** showed eight of his 14 cases. These he grouped into four classes. In the first (three cases) there had apparently been complete recovery, though the diagnosis was very definite. The second group consisted of those who had recovered, but self-control was deficient: they were emotional, or kleptomaniac, or immoral in some other way. This was, he said, a very important class, as, owing to the disease, there were children who were liable to commit various offences. In the third group, in addition to mental impairment, the children had choreiform or athetoid movements. Those in the fourth group were of the Parkinsonian type; like paralysis agitans, they had tremor, rigidity, a toneless voice, slow speech, mask-like face, salivation, and increased reflexes. He had five of these cases, and all were inmates of asylums.

Dr. **CROWLE** showed two cases of the Parkinsonian type. The disease was not recognised, and they came under her care two years afterwards. One was a girl, aged 17, sent home from work because she was biting the inside of her lips and could not be checked. Some considered she had a peculiar form of influenza, others that she was the subject of hysteria. Her temperature was up, and she had attacks of rapid breathing and some diplopia, and was said to have been unconscious a week. The illness was ushered in by some days of insomnia. Excessive salivation was long a trouble. Mentally she was quite alert, but her movements were unnaturally slow. The second patient, a girl aged 21, who had her illness in 1920, was supposed to have dementia præcox. Her condition had never been recognised as an illness, she had not been in bed because of it, and even during her insomnia she continued to go to her work, but became very sleepy over it. She took a holiday, but continued to get up daily and to fall asleep over whatever she might be doing. Three months after returning to her work (clerking) she noticed she was very slow over her figures, and her muscular responses were also very sluggish. She was not mentally dull. After six months the sleepiness gradually lessened. She now showed the mask-like face and had some tremor of the left leg, with salivation and hesitation in speech.

Dr. E. A. **COCKAYNE** showed a girl, aged 12, whose illness began with diplopia and weakness of the left arm. She now had continuous rhythmical movements of the upper lip on the left side; this quickened when she was tired, and during sleep. Since the illness her disposition had definitely changed for the worse, and while at school she had periods of extreme sleepiness, during which she was indifferent to all that went on around her.

Dr. C. P. **SYMONDS** showed a boy whose history it was difficult to ascertain. The mother said he became very drowsy, and as he later developed twitching movements he was admitted to an infirmary as a case of chorea. He remained six months, and then was noticed to have nocturnal restlessness, and now was of the Parkinsonian type, and subsequent changes so affected his mentality that he was now an inmate of an asylum. He was now sleeping well.

Dr. C. **WORSTER-DROUGHT** exhibited a boy, aged 12, who in June, 1920, had twitching of the mouth and left leg, and, a few hours later, drooping of eyelids and lassitude. When admitted he was profoundly lethargic, and showed katatonia and bilateral ptosis. The cerebro-spinal fluid showed two lymphocytes per c.mm.; weak positive globular reaction (Noguchi), negative Wassermann, and a good reduction in Fehling's solution. On June 23rd he developed a tremor of the left arm, and occasional clenching of the left hand associated with transient loss of consciousness. For about 18 months he slowly improved, but during the past 12 months there had been a gradual deterioration.

Discussion.

The **PRESIDENT** said some writers on this subject appeared to be very pessimistic as to the outlook in these cases. One Scandinavian writer said practically in all cases the illness left something behind. In a collection of cases made in Indiana, numbering 300, 25 per cent. ended fatally, 25 per cent. had only insignificant after-effects, and 50 per cent. had serious sequelæ. Certainly in earlier days there were many failures to diagnose the condition. It was almost impossible to diagnose sleeping sickness in a baby; plenty of sleep was accepted as a sign of good health, yet the later appearance of some such babies suggested they were victims of a mild form of the disease.

Prof. **ARTHUR HALL** (Sheffield) said the symptoms of the disease described as occurring in children were found in adults too, but differently balanced. He mentioned the case of a medical man who had periodic attacks of hyperpnœa, followed by long periods of apnœa. The after-effects of the disease were sometimes appalling. One case he saw was that of a boy who apparently had myasthenia gravis. Five years later he had apparently recovered, but was left with a spasm of the face and mouth, and every few seconds his jaw dropped. The moral effects in children were often of a very serious kind. He gave some instances.

Dr. **PARKES WEBER** thought that in examining these cases more care should be taken in excluding mental abnormality, so as to avoid surprises and difficulties when the patients sought work. He referred to a case which presented a remarkable example of bradykynesia (delayed movement); the movements were so slow as to resemble the slowed movements shown for purposes of analysis at the kinema. He had seen a similar lethargy in responding to questions.

Dr. F. C. **SHRUBSHALL** spoke of the help in tracing the histories of these children which could be afforded by the school service in London. This organisation possessed records of 60 children who were supposed to have had encephalitis lethargica. These children showed apathy, and failed to get on at school; some were moral delinquents. But he insisted that the application of educational methods early would obviate many of these children having to be sent to an asylum. Before declaring that a child was a subject of permanent mental defect, he should be under prolonged observation.

Dr. H. C. **CAMERON** agreed that the abnormality of conduct seen in these children did not differ in type from the abnormality noticed to ensue from faulty parental management; it amounted to a manifestation of the strong desire to make a sensation and attract attention to itself. The change of temperament brought about by the disease was a very serious matter.

Dr. A. S. **MACNALTY** said that in their efforts at the Ministry of Health to follow up the cases of the disease which were notified they had not found one with the Parkinsonian syndrome. A book had recently been published incorporating the experience of Prof. Pierre Marie and Dr. Gabrielle Levy, stating that out of 129 cases, 70 had the Parkinsonian syndrome. It would be interesting to know whether the comparatively phlegmatic population of Scandinavia produced more instances of that syndrome than did the more excitable Latin races. He was glad Dr. Shrubshall had some faith in education in mitigating the mental sequelæ; but the prognosis in the severe cases was not yet properly known; it certainly was very bad in the Parkinsonian cases. At present the prognoses given should be very guarded.

Dr. C. P. **SYMONDS** remarked on the small proportion of cases coming up with sequelæ in which the diagnosis was made at the time of the illness, mostly because it had been of only mild intensity, yet the after-results were sometimes very grave. The latent period might last as long as two years, and the virus might have been smouldering in the patient all the time. In a woman aged 38, who had a mild initial illness and severe Parkinsonian symptoms which proved fatal, sections through the corpus striatum showed some perivascular cupping, and a marked hyaline degeneration of the small arterioles, which had gone on in some instances to calcification. That supported Dr. Buzzard's view that the sequelæ were due to progressive degenerative and obliterative changes in the vessels, and consequent anæmia of the nervous tissues.

Dr. D. **MACALPINE** said he had seen over 30 cases. Of these, 10 had a latent period of at least six months (between the original attack and the first sequel).

The periods varied up to three years nine months, the latter being the case of a woman aged 39, who had an illness in 1918 characterised by insomnia, paresis of accommodation, and paralysis of one side of the face. In three months she said she was all right, and returned to her work as a saleswoman. She kept well until last August, then had blurring of sight, insomnia, and two months later had the Parkinson syndrome. Voitz and Ramsay Hunt considered that the lesion was in the globus pallidus, but another authority placed it in the substantia nigra. He, the speaker, was at present working on a case which died of the Parkinson condition 18 months after the attack, and it was already clear that the main lesion in that case was in the substantia nigra, though there were other changes in the corpus striatum.

SECTION OF OTOLOGY.

A meeting of this section of the Royal Society of Medicine was held on Jan. 19th, Dr. **Logan Turner** (Edinburgh) occupying the chair.

Labyrinthitis Complicating Middle-Ear Suppuration.

Dr. **Logan Turner** and Mr. **J. S. Fraser** submitted a contribution on this subject. It consisted of a classified presentation of the result of 15 years of work in the special department at Edinburgh Royal Infirmary—1907–1921. In the early part of that period the examination of the static labyrinth was in a more or less experimental stage; and it was possible the earlier observations were not as accurate as the later ones. They were dealing only with middle-ear suppuration and labyrinthitis as a complication of tuberculous disease. During the 15 years they examined 8864 cases of middle-ear suppuration, 2172 being acute, 6692 chronic. The secondary labyrinthine cases numbered 117, or 1·3 per cent. In 7 cases the labyrinth disease was bilateral, and altogether they had under care 10,653 suppurating ears. Of the total, 1·1 per cent. had labyrinth infection secondary to middle-ear suppuration. Of the 117 cases 75 were males, 42 females. Most of the labyrinthitis cases occurred in the first four decades of life. The 117 cases were divided into (1) acute and subacute middle-ear suppuration, and (2) chronic cases. One acute case had circumscribed labyrinthitis, as verified post mortem by microscopical examination; there were 3 of diffuse acute serous labyrinthitis, 4 of chronic latent labyrinthitis complicating the acute condition. In the 100 chronic cases there were 26 of circumscribed labyrinthitis, 14 of the acute manifest disease, 46 of the latent form, and cured cases 14. The duration of the discharge in the chronic cases seemed to have no bearing, but the relationship of cholesteatoma was interesting. Of 100 cases of labyrinth infection, cholesteatoma was present in 57, absent in 36, and in 7 there were no data on the point. Of the circumscribed labyrinthitis cases, cholesteatoma was present in 65 per cent., and in 69 per cent. of the acute purulent ones. Polypus was present in 31 of the chronic cases, half of them had cholesteatoma. The authors warned against snaring polypi without a previous careful examination of the labyrinth. In only 12 of the 117 cases had facial paralysis been found, but in the tuberculous ear cases 45 per cent. had this complication. Pathological changes were found in the outer wall of the labyrinth in 53 per cent., fistula in the lateral canal in 46. Cholesteatoma was found in 35 of the 59 cases, and it was absent in 24. Of the 117 cases 72 came into hospital without any intracranial complication, 45 being admitted with such. Of the 72, 11 were complicated by acute middle-ear trouble and 61 of the chronic. The 45 admitted with intracranial complication were divided into two groups: (*a*) those in which such complication was traceable to the labyrinth (24 cases); and (*b*) cases associated with labyrinth affection, but not directly traceable to it (21 cases). Of the 61 cases with complicated chronic middle-ear suppuration, 19 were circumscribed labyrinthitis, and 18 of these had the radical mastoid operation performed, and all recovered. In a total of 31 labyrinth operations, there were no deaths. Of the 24 cases which were regarded as secondary to labyrinth complication 20 were cases of meningitis, 4 were cerebellar abscess. There were operations on 20 cases of meningitis. Two were moribund when seen and died shortly after admission; 15 had labyrinthectomy done, and 3 the mastoid operation. There were 20 recoveries. Of 1720 mastoid operations done in the period under review, there were only 6 cases of post-operative labyrinthitis—i.e., 0·3 per cent.—so that the operative risk was very low.

Mr. **Fraser** showed, by means of the epidiascope, fine micro-photographs of a large number of cases, giving a short clinical summary of each.—Mr. **Albert A. Gray** (Glasgow) highly praised the beauty of Mr. Fraser's slides.

Mr. **Sydney Scott** had seen only one case in which the whole labyrinth had been replaced by bone tissue, and as the case came from a Poor-law infirmary there was an absence of history. He supposed such a condition was due to infection. He spoke of a type of case sometimes occurring in patients with cholesteatoma or granulations, but with no sign of internal ear disease or of labyrinthitis, and in whom, a month after the operation, a small granulation on the inner wall was seen. If this spot were touched, violent vertigo, forced movements, and nystagmus ensued. Probably that was because the layers of bone which formed outside the canal became so thin and soft that pressure was transmitted to the labyrinthine fluid. That sign did not cause him to conclude that the labyrinth must be opened. Usually the condition gradually subsided if left alone. The cases under discussion must be diagnosed early, and it was a condition with which the general practitioner should be better acquainted.

Mr. **G. J. Jenkins** confirmed Mr. Scott's description of cases occasionally met with a month after operation in which violent vertigo followed the touching of a small granulation on the inner wall.

The authors of the paper briefly replied.

Vertigo with Fixation of Ossicles.

Sir **James Dundas-Grant** showed a case of this condition which was cured by the operation of ossiculectomy. The patient, a male aged 24, had such severe attacks of giddiness that he fell. He had chronic suppuration in the left ear, which was dealt with satisfactorily by a modified mastoid operation; but the vertiginous attacks persisted and could be excited by even slight pressure on the *right* (the opposite) tragus. The right malleus was found tied down to the promontory by cicatrices. After removal of the ossicles the vertigo almost disappeared, and pressure on the tragus no longer induced it.

Parotid Fistula Following Mastoid Operations.

Mr. **Norman Patterson** showed a girl, aged 12, who had had right otorrhœa, on and off, since infancy. When seen she had a purulent discharge from the right ear, and her posterior meatal wall bulged. She had posterior perforation and tenderness over the mastoid. Mr. Patterson at once did a complete mastoidectomy and found cholesteatoma in the middle ear. The lateral sinus appeared healthy. Two days later he reopened the wound and removed blood-clot and sloughs. The internal jugular vein was ligatured. For a week the oscillating temperature rose to 104° F. Five months later a swelling was seen in the operation scar and this burst. It was found subsequently to be coming from the parotid. It was now intended to cauterise the fistula.

Unusual Condition after Radical Mastoid Operation.

Mr. **Scott** showed a case in which he performed the radical mastoid operation for cholesteatoma and chronic suppurative otitis, and found bony ankylosis of the body of the incus to the tegmen and aditus. In the general run of such cases there was no incus. It was necessary at the operation to cut away the tegmen, as there was a true synostosis with the incus, the latter being perfect in every detail.

HUNTERIAN SOCIETY.

GASTRIC AND DUODENAL ULCER.

THIS Society met on Monday evening, Jan. 29th, for the first time in its career, in the salon of the Mansion House, by courteous invitation of the Lord Mayor. The chair was occupied by Dr. FORTESCUE FOX, the President of the Society, and there was a large attendance.

Sir BERKELEY MOYNIHAN delivered the Hunterian Lecture on Gastric and Duodenal Ulcer. He said that the surgeon was apt to form conclusions rather from dramatic occurrences than from the daily placid routine. A review of past work served to correct impressions, often vague, sometimes very treacherous, or to confirm a faith which had grown almost imperceptibly. He had passed in review his surgical work on gastric and duodenal ulcer in the last ten years. The literature on the subject was formidable in bulk, but its value was not in proportion to its volume. Much of it had to be taken on trust, and he felt that no further progress could be made until, when talking of gastric ulcer, one could be sure that a gastric ulcer was actually present. Gastric ulcer was said to be of two kinds—acute and chronic. The chronic was an ulcer with a deep crater, steep and overhanging edges, in which there were present not only the evidences of destruction, but also evidences of defence, sometimes very stubborn defence. It was a cause, but not the only cause, of recurring symptoms; for in operating on patients in the intervals between attacks the open crater of an ulcer could still be seen. Possibly the thoroughly callous ulcer did not produce symptoms until the acute process was set up at its edge, or when, in connexion with acute ulcer, there was evidence of reinfection in the development of acute ulcer round the edge of the chronic ulcer, or when the scar of an old ulcer broke down and a new ulcer developed. An acute ulcer was generally a terminal event; it was evidence of acute infection, or of a toxæmia which expressed itself in the stomach by an impediment to the vascular supply, and the consequent impoverishment of a certain area of the gastric mucosa.

Chronic Ulcer of the Stomach and Duodenum.

He proposed to devote his address to a consideration of chronic ulcer. During the last ten years he had operated upon 718 cases of chronic ulcer of the stomach and duodenum. There were 531 cases of duodenal ulcer (433 males, 98 females). His last death in a case of duodenal ulcer occurred in 1912. There had been over 500 cases in since, without a death. Of the cases of gastric ulcer, there had been 164 (83 males, 81 females); gastric ulcer with duodenal ulcer, 23 cases. Thus, in 187 cases of gastric ulcer, duodenal ulcer had been present in 12·3 per cent. So far as was known, of the total number of patients operated upon, six had developed jejunal ulcer. Into the literature there was creeping the word "juxtapyloric" in connexion with ulcers of the stomach and duodenum. Such a word was unnecessary; it was only a peg upon which to hang a half-truth. Ulcer was either in the stomach, or in the duodenum, or in both, and no one having a real acquaintance with the living subject could have any difficulty in saying, in the overwhelming majority of cases, whether an ulcer was in the stomach or in the duodenum. In only three of the 718 cases was there doubt as to whether the ulcer was gastric or duodenal. Pyloric stenosis was almost always duodenal, and pyloric ulcer was, for academic purposes, unknown. Concerning gastric ulcer, the first thing desired to be known was as to the possibility of making a clinical diagnosis. Gastric ulcer was a rare disease, and he did not think the diagnosis of any abdominal conditions was so apt to be wrong as the diagnosis of gastric ulcer. If that was true, most of the treatment which had been applied to supposed gastric ulcer was being applied to a whole series of different diseases.

Symptoms.—As to the symptoms of gastric ulcer, the pain was characterised by its extreme punctuality. Where there were caprice and irregularity in the onset of the pain in reference to meals, the clinical history should be distrusted from the first. In gastric and duodenal ulcer the diagnosis depended on the rhythm. The rhythm of gastric ulcer was, that the patient was comfortable after a meal for a time, time varying according to the position of the ulcer. Then pain came on, and it passed off before the next meal was taken. Thus the rhythm was—food, comfort, pain, comfort. With duodenal ulcer the rhythm was not quadruple, but triple—food, comfort, pain, until food was taken again. In a search through the records it was found that three-fifths of the cases of gastric ulcer had pain appearing within one and a half hours of taking food, and that four-fifths of the cases of duodenal ulcer had pain appearing over two hours after the taking of food. Vomiting and other symptoms were quite infrequent in gastric ulcer, even when considerable obstruction was present. Often the patient had never vomited; he was able to gauge the capacity of the stomach, and took only such quantity as would pass readily into the duodenum. The cardinal happening, hæmatemesis, was the most treacherous thing of all. Even to-day students at hospital had the idea that hæmatemesis meant gastric ulcer, whereas this symptom usually meant cirrhosis of liver or splenic disease.

Diagnosis.—As to diagnosis, when the old physicians spoke of gastric ulcer they were usually thinking of duodenal ulcer. Even after the closest scrutiny of a clinical history had been made, no clinical diagnosis of gastric ulcer should be accepted. It was safer not to diagnose gastric ulcer unless one was supported by the ancillary methods. Of these the best was radiology. He found that the niche (which was demonstrated by photographs) indicated the presence of a crater, and the notch showed spasm; both these were unmistakable signs of gastric ulcer. In Sir Berkeley Moynihan's own series of gastric ulcer cases the orthotonic, the hypotonic, and the hypertonic stomach occurred in exactly equal numbers. In duodenal ulcer the stomach was orthotonic in 44 per cent., hypotonic in 24 per cent., hypertonic in 32 per cent.

The next important ancillary method was the fractional analysis of stomach contents. He had 420 charts taken on the old test-meal method, and he obtained from them so little information that he abandoned it. For a little more than a year the fractional meal method had been employed, and Dr. Bell, of Melbourne, had been doing this. The results were as follows:—

108 Cases of Ulcer.

	GASTRIC (total cases 38).			DUODENAL (total cases 70).		
	Cases.	Per cent.		Cases.	Per cent.

Medical versus Surgical Treatment.

Assuming that the diagnosis which had been made was accurate, what was to be done ? He never offered advice to a patient ; he imagined himself in the patient's place, and asked what he would wish to be told. He felt that his position was that of a physician who was doomed to practise surgery. One of the things evident to the surgeon was the gross ineffectiveness of medical treatment for these conditions. If we considered the processes which must take place before gastric ulcer could heal, it was obvious that it was impossible for the hospitals to undertake the medical treatment of it, and private patients would not put up with the wearisome prolixity of treatment. As soon as medical treatment had been well started, the symptoms rapidly abated, but it was another matter to cause their disappearance. The treatment must go on for a long period. In treating medically, a search should be made for the foci of infection. The commonest of these were in the mouth or the accessory sinuses. The patient was then dieted and alkaline treatment begun. But why alkaline treatment ? In 50 per cent. of cases of gastric ulcer there was diminished acidity, in only 50 per cent. hyperchlorhydria. He had not heard it argued that the giving of alkali provoked increased acidity. And why were alkalis given in both gastric and duodenal ulcer, in which the chemical conditions were dissimilar ?

In the 718 cases referred to, Sir Berkeley Moynihan had removed the appendix 307 times, the gall-bladder 23 times. In over 50 of the patients the appendix, or the gall-bladder, or both, had been previously removed. In at least two or three cases in which the appendix was removed, the disease of that part appeared to have antedated the ulcer, or the conditions in and about the appendix were so gross that they could be regarded as probably causal lesions. Medical treatment gave no clue as to the infections in operation in the abdomen. If it was essential to get rid of oral sepsis before beginning treatment of gastric ulcer, it was equally necessary to get rid of other infections, the chief of which were inside the abdomen ; and the relapses which so frequently occurred might be due to the fact that there had been treated only one aspect of a large disease. Prof. Matthew Stewart went through the post-mortem records of the last ten years in Leeds—the period covered by the present statistics—and found that during that time 75 patients had died in Leeds Infirmary from hæmorrhage or perforation in connexion with a gastric ulcer. There were 61 cases of perforation, 60 of them in chronic ulcers. There were 14 cases of hæmorrhage, 13 of them in chronic ulcers.

With regard to duodenal ulcer, they had had 129 deaths from hæmorrhage or perforation in that period. There were 117 cases of perforation. In 12 of of them there was acute ulcer, in 4 it was a chronic ulcer existing at the same time, which had perforated. There were 12 cases of hæmorrhage causing death from duodenal ulcer, and in every case the ulcer was a chronic one. It was impossible to be sure how many of the cases had undergone treatment, and the complete clinical history could not be obtained in all ; but the majority had had medical treatment several times.

With regard to the question of carcinomatous degeneration of a chronic gastric ulcer, that was very controversial. It was still true that two out of three patients on whom he operated for cancer of the stomach gave a history which might be accepted as that of gastric ulcer. The pathologist found carcinoma already present in 18·5 per cent. of the cases, and the general average of carcinoma for the whole hospital was 11·5 per cent. In addition to ulcers which were apparently simple, there were ulcers which showed one edge upraised, thickened, and soft, and in such carcinoma was found. He had one specimen of a chronic ulcer showing scirrhus carcinoma at one edge, columnar carcinoma at the other. If the ulcer began as a carcinoma, which kind was there first ? It might be said that duodenal ulcer never became malignant. Upon two patients he did gastrectomy for chronic gastric ulcer, and they died of either carcinoma of the stomach or a recurrence in the liver. He did not think there existed evidence that medical treatment had cured gastric ulcer. And the dangers of medical treatment were formidable, much greater than those attending operation ; the physician should now realise that medical treatment was far less effective than surgical treatment to-day.

As to the best surgery, opinion was still divided. Gastro-enterostomy gave good results in a certain number of cases, but the results were not yet good enough. The mortality from this operation was larger than that of gastrectomy. There was no place to-day for gastro-enterostomy for the cure of gastric ulcer. It was true the operation was simple, it was so simple that it was practised by the inexpert surgeon. Balfour's operation of cauterising the ulcer and then doing gastro-enterostomy gave him (Balfour) good results in certain cases. Sir Berkeley Moynihan himself did only two operations. If the ulcer could be got away, he did gastrectomy. If the position of the ulcer was so inaccessible, its size so great, and its adhesions so profound that the patient could not stand removal of the stomach, he did gastro-enterostomy and jejunostomy, and fed the patient entirely through the jejunostomy tube. The slow healing of the ulcer was watched by means of X rays. The only operation which would survive was that which would relieve the patient of his immediate troubles, and afford the greatest warrant against any late results due to either physiological effects, or to the mechanical effects of the operation. He had had only four unfavourable results from gastrectomy.

Finally, he had an inspiring word for operators. The surgeon must have courageous faith, using meticulous care, for, in the last resort, the operation was a test of the spirit, and there were few things a man could not conquer if his heart was set on victory.

Sir Berkeley Moynihan showed a number of slides of micro-photographs showing the depths to which ulcers had penetrated, and skiagrams demonstrating the nitch and notch he spoke of as diagnostic X ray evidences.

Discussion.

Dr. **BELL** said the interpretation of the curves of fractional gastric analysis had not yet been fully worked out ; there was need of more knowledge on normal curves. The most notorious type of curve was that due to duodenal ulcer ; it was a rapidly-rising curve with continued secretion. Statistics based upon medical diagnosis were found to be very fallacious. The dependable curve was that of pernicious anæmia, which was found to be invariably accompanied by hyperchlorhydria. The classification of the six types mentioned by Sir Berkeley Moynihan was only arbitrary. It was difficult to get negative occult blood reactions during the treatment of gastric ulcer. After symptoms had disappeared and X rays showed no further nitch, there were still traces of occult blood in the fæces.

Mr. **HERBERT CARSON** thought the large question raised by Sir Berkeley Moynihan was whether the cases under discussion should be regarded as medical or surgical. The idea that these cases should never be turned over to the surgeon until they had been given a long course of medical treatment led people astray. Acute ulcer was a very different thing from chronic ulcer, and surgical treatment might well be confined to the latter. The surgical procedure tended to be more drastic in getting rid of the ulcer, because of the unsatisfactory results obtained from a less drastic procedure. Another reason was the bugbear of malignant degeneration. As to this the surgeon was more confident than was the pathologist. The chief tendency was to call a case simple when it was malignant, rather than the other way about. Because of these mistakes, it seemed to be safer to do some form of gastrectomy. He had given up the Balfour operation. The " sleeve " operation had given good results in his hands.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

AT a meeting of this Society held on Jan. 19th at 1, Upper Montague-street, London, W.C., Prof. T. EUSTACE HILL, the President, being in the chair, a paper was read by Prof. E. MELLANBY on

DIET, AN IMPORTANT FACTOR IN PREVENTIVE MEDICINE.

He said that much ill-health and mortality were due to bad methods of feeding. The study of diet might throw light on the epidemiology of many diseases not now understood. He was of opinion that much of the decline in infantile and other mortality was due to improvement in diet, and not merely to better environmental conditions such as housing. Most of the foods forming the staple diet of the working classes were deficient in fat-soluble vitamin; their tastes were not always a good guide as to what food was the best. For instance, the starchy foods and sugars which children desired were not the food they most needed. In the diet of adults cereals and butchers' meat, which usually took a great place, were supplemented by potatoes, pulses, lard, vegetable margarine, jam, and tea, coffee, and cocoa. These constituted the staple diet. Milk, cheese, eggs, and green vegetables were neglected. The diet was deficient in calcium, which, with the lack of the fat-soluble vitamin, accounted for a great deal of ill-health.

Pre-Natal Influence.

The influence of diet in pregnant women had not been much worked at, and Prof. Mellanby described some recent experiments that he had carried out with a pointer bitch. When she was deprived of the fat-soluble vitamin in an otherwise perfect diet during the last four weeks of pregnancy, all her puppies died within 11 weeks of birth. When she had this diet from the beginning of a subsequent pregnancy she aborted within eight weeks. And in a third pregnancy, when cod-liver oil was added to her diet she bore a healthy litter of seven, all of which throve well. The female had a great power of sacrificing her own tissues for the benefit of the developing fœtus, but there was a limit to this power, and therefore the diet in pregnancy was most important. It might be an important factor in the high pre-natal mortality which was so little understood.

Deficiency Diseases.

The speaker, discussing the relation of rickets to diet, instanced the islanders of Lewis, who lived under extremely insanitary conditions and yet were free from the disease and had perfect teeth. Their diet was rich in oily fish, milk, and eggs. Lantern-slides were shown demonstrating the action of the fat-soluble vitamin in rickets. Mrs. Mellanby's work in connexion with the teeth of puppies was also referred to, the dentine as well as the enamel being affected by deficiency of the vitamin. Ordinary inspection of children's teeth did not reveal this deficiency, except when they actually developed caries, but microscopical examination of the teeth from about 300 children showed that 84·5 per cent. were hypoplastic. He suggested that diet was the solution of the problem of defective teeth. He then quoted McCollum's work on rats, which showed that in respect of growth and fertility, butter could not exert its beneficial influence in the absence of calcium salts. For that reason milk was much better in that respect than butter. The outbreak of keratomalacia (xerophthalmia) in Denmark during the butter scarcity caused by the war was referred to, and its extirpation when an adequate ration of this fat was arranged for by the Danish Government. This was a unique case of the prevention of disease by official action in regard to diet. Stress was also laid upon successful treatment of infantile marasmus by a diet containing the requisite vitamins. The speaker said that rickets and marasmus were both completely preventable by proper diet. At the present time in London it was difficult to find florid cases of rickets for demonstration, and this he attributed to the work of infant welfare centres in regard to diet. It was the diet reform accompanying the child welfare movement that he regarded as primarily responsible for the great decline in infantile mortality. Prof. Mellanby contrasted the action of cereals and of the fat-soluble vitamins, with especial reference to the antagonism of bread and fat in the diet of puppies. An excess of bread tended to a fat, lethargic condition, while the influence of vitamin-containing fat *plus* calcium made for activity and rapid metabolism. The more bread that was taken the greater the amount of the fat-soluble vitamin required to maintain health.

In conclusion, Prof. Mellanby made the following practical suggestions: The consumption of cod-liver oil should be greatly increased. Teaspoonful doses were sufficient. It was the cheapest source of the vitamin on the market. More milk ought to be consumed. The eating of green vegetables, especially raw salads, should be encouraged. He would like to see calcium carbonate added to butter, say about 2 per cent. The difference this made was most striking. Adult diet should be regulated so as to contain more fat-soluble vitamin and calcium.

After concluding his paper, the speaker was asked to discuss the recent work on the action of sunlight in preventing and curing rickets. He stated that the Lister Institute experiments had shown that while the exhibition of sunlight on the uncovered body had a similar action to the administration of the fat-soluble vitamin, provided that the vitamin was merely deficient in amount in the body, and not entirely absent, yet if there were none of the vitamin at all the sunlight failed to produce this effect.

Discussion.

The PRESIDENT, in thanking Prof. Mellanby for his paper, said that it was now time for medical officers of health to act upon the new discoveries in dietetics. The description of the nutritional condition of adults in the industrial classes was only too true. Great improvement had taken place in the health of young children in Durham county coincidently with the increased consumption of dried milk; but there was a great deal of rickets amongst the school-children and adults. In view of the stress laid upon the calcium constituent of the diet, he asked whether there was any evidence of rickets being less prevalent in districts with a hard water-supply.

Dr. J. WHEATLEY (M.O.H., Shropshire) said that this was a matter in which it was important to teach the people to act for themselves. No line of action in improving the public health was more promising, and the Government should promote propaganda on the subject. In this matter the propaganda was more difficult than the research. The calcium deficiency in our diet he attributed to the fractioning of many articles of food. It was abundant in milk, but this was not intended as a food for adults, and we needed other foods rich in calcium. He raised the question whether calcium in mineral form could take the place of calcium in organic combination.

Dr. W. J. HOWARTH (M.O.H., London) raised the question to what extent tuberculosis was to be regarded as a deficiency disease. He instanced its parallelism with rickets in three respects—viz.: (1) The curative effect of sunlight in surgical tuberculosis; (2) the effect of cod-liver oil, which had for decades been regarded as a specific in the disease; and (3) the correlation between the mortality from tuberculosis in this country and the consumption of certain foodstuffs during the past century. He also questioned whether the mortality from influenza in 1918–19 was connected with the lack of fats in the national diet at that time. He thought that consideration should be given to the question whether the sale of margarine containing no animal fat should be prohibited or its constitution declared.

Mr. R. D. PEDLEY stated his opinion that Mrs. Mellanby's work would simplify the great problem which the care of children's teeth presented. It was now enacted that dental as well as medical treatment was to be provided for children in public elementary schools, and dietetic prevention would make a great saving.

Dr. T. S. **McIntosh** (M.O.H., Hendon) said that more information was needed on the effect of boiling, pasteurising, and drying on the vitamin content of milk.

Dr. T. **Evans** (M.O.H., Swansea) mentioned that in certain rural parts of Wales, where there has been much deterioration in the teeth, there has also occurred to a great extent an abandonment of the agricultural practice of liming the soil.

Dr. W. W. **Jameson** (M.O.H., Finchley) remarked on the number of breast-fed children who afterwards did badly; he almost thought that the artificially fed had done best. He suggested that this was due to lack of vitamins in the tissues of the mothers.

In the course of his reply Prof. **Mellanby**, dealing with the influence of lime salts in water, instanced the extremely bad teeth to be found in Sheffield, where the water was very soft. He did not think it was a vital factor. Oil rich in the vitamin could be obtained from the liver of other fish than the cod, and the oil from the muscular tissue of herrings was very good. He believed that improvement in diet was the most promising way to deal with tuberculosis in this country. Refined cod-liver oil was as good as the crude, but the refining was a wasteful process, because the rejected stearin was just as rich in vitamin as the refined oil. He himself used the unrefined oil.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

This section met in the Royal College of Physicians of Ireland on Jan. 12th, Dr. T. **Hennessy**, the President, being in the chair.

Dr. **Horace Law** read a paper on

Hospital Finance.

He pointed out that it was not the custom for hospitals to have balance-sheets like a company, showing their capital expenditure as well as their yearly receipts and expenses; the costs of sites and buildings were written off and forgotten. In spite of the deficit incurred during the war, the hospitals of Dublin were not in serious debt. For many years past, however, the annual income did not balance the expenditure and was supplemented by bequests which were used as income. Dr. Law sketched the development of the Board of Representatives of the Associated Dublin Hospitals. This board had been engaged chiefly in studying the means of increasing income. The ideal method was for the people to subscribe small weekly sums, when well, so that the hospitals might care for them when sick. An agreement with one of the branches of the Irish Transport and General Workers Union had been made embodying this principle. A system of payments by urban and rural sanitary authorities for necessitous patients coming from their areas was in force in connexion with about 60 of these bodies. Arrangements had also been made with the National Health Insurance Commissioners whereby the approved societies might include hospital benefit as one of their extra benefits. Under the schemes of the board of representatives the patient had free choice of hospital, the payments being made by the board to each hospital in proportion to the work done in treating patients. Dr. Law, while acknowledging the economy and increased efficiency which would result from amalgamation of hospitals, thought this end at present impossible of achievement. Further, he pointed out that the smaller hospitals permitted of the patient being individualised, with the result that the patient subsequently took an interest in "his hospital." The great increase in all hospital expenses was dealt with and it was pointed out that the nursing staffs were now being treated with greater justice.

Sir **Joseph Glynn** said that in Ireland it should be an easy matter to make a new start in connexion with the hospitals. State control would kill the hospitals, and should only be accepted as the last possible expedient. There were now two ways in which this question could be approached: (1) The rate in aid, through the county councils, had the disadvantage that if any one of the 26 counties stood out there would be difficulties, and in any case a pool board would have to be set up to distribute the money; (2) the grant in aid was the scheme used in connexion with child welfare schemes at present working in Ireland and was favoured by the speaker. Incidentally, he was of opinion that some of the hospitals in Dublin could make claims on this scheme; certainly the Children's Hospital could. The hospitals treated the sick people of the State, and trained doctors and nurses for the coming generation. The service which the hospitals were doing to the State was quite beyond any aid which they got from the State. He was of opinion that for every £1 raised £1 should be given by the State, up to 50 per cent. of the annual expenditure of the hospitals. The annual accounts of the hospitals should be given to a public auditor to be certified. Such a scheme would give the officials of the hospitals a chance to devote their time to hospital work, instead of spending time in raising money for them. The Government would probably welcome any really solid proposal.

Sir **John Moore** said that one point not mentioned was the proposal of granting a fund to provide equipment for the hospitals; this expensive item was hardly a proper charge on the voluntary subscription lists of the hospitals. It should be met by the State.

Sir **James Craig** said that he had opposed State aid, where State aid meant State control, as he felt that the hospitals would never be managed in the same way under State control as they were now managed. There was no doubt that the hospitals were in a serious condition. As to lotteries, no matter how careful control was exercised, they could not tell how much fraud went on in connexion with these. He said he would not allow these lotteries to go on unless a Bill was brought in by some private member legalising lotteries in connexion with charitable institutions. Regarding child welfare, there was no reason why each hospital should not have a member of the staff in the out-patient department doing work in connexion with this scheme, which was capable of very great extension.

Dr. R. J. **Rowlette** said that some years ago the hospitals came to the conclusion that they were admitting, and treating free of charge, patients who were well able to pay for their maintenance, and they therefore decided that all patients should contribute as far as they were able to the funds. In some cases this idea had been overdone. Treatment should be given to patients free, if they were unable to pay for it. If the hospitals relied too much on payment from patients, they would injure both the patients and the hospitals. Some patients who were unable to pay for their maintenance in hospital were now shy of asking to be admitted without paying, and if they paid, their families at home starved. The hospital governors found it easier to get money from the patients than to ask for it from the public. Now that the patients paid, the voluntary subscriptions had fallen off. He did not see how a hospital which would be dependent mainly on Government grants could resist State control. He would prefer voluntary control, though he would have no objection to Government supervision. There was one question which had not arisen here yet, but which would later on, in connexion with payment from the patients, namely that of payment of hospital staffs. If the hospitals were not charitable institutions, there would be no claim on the doctors to give their skill and time free to these institutions. He hoped that the question of amalgamation of the smaller hospitals in Dublin would not be lost sight of.

The **President** said that the Dublin hospitals were worthy of support from the public and also of a grant from the State. Very few of the hospitals in

Ireland were fully equipped; some of the country hospitals had been closed, with the direst consequences. In Cliffden, co. Galway, some people were 70 miles from the county hospital, and had to be sent to it by sea. In most of the workhouse hospitals the sanitary accommodation was not at all up to date, and he would not like to see the people in Ireland wholly dependent on the city hospitals. Patients admitted to hospitals should come under three classes: (1) free or indigent patients; (2) tariff patients; (3) paying patients.

Dr. **LAW**, in reply, said that the question of payment for accident cases had not been discussed. Hospitals had been established specially for this type of patient, and they should be freely admitted. He agreed with Dr. Rowlette that the hospitals were abusing payment of patients. It should not be forgotten that the hospitals were first of all charitable institutions. There were free beds in all the hospitals, but in some they were very difficult to find. At the hospital to which he was attached they had appointed a paid almoner to deal mainly with the out-patients. This work had been most successful. He was of opinion that lotteries were quite wrong, as he believed that if money was to be got for the hospitals, it must be got by clean methods.

MANCHESTER PATHOLOGICAL SOCIETY.

A MEETING of this Society was held on Jan. 17th, with Prof. **SHAW DUNN**, the President, in the chair.

Mr. E. F. **GUY** read a paper on the

Fractional Test-Meal and the Information obtained from it in Ulceration of the Stomach and Duodenum.

The paper was based on an analysis of 60 cases from a surgical clinic in 36 of which the presence of an ulcer had been confirmed at operation. He had found a hyperacid resting juice in duodenal ulcer, with a continued high acidity persisting after emptying of the stomach. On the motor side there was "hurry," emptying in less than the normal two and a quarter hours. In gastric ulcer, particularly ulcer of the body of the stomach, the acidity was generally low and emptying was delayed. Blood might be present in both duodenal and gastric ulcer. With pyloric ulceration stasis was a prominent feature, with an acidity which rose to a high level during the digestion of the meal. The resting juice in this category was low, and the after secretion not commonly very acid. Mr. Guy showed charts of cases before and after operation, demonstrating that the amount of reduction of acidity was not constant but depended on the character of the gastric secretion before operation. Even after pylorectomy the acidity might remain high, and emptying was often very hurried.

Mr. **GEOFFREY JEFFERSON**, on whose cases these tests had been carried out, said that he thought these charts showed in concrete form facts of which medicine had before been clinically aware. For instance, the commonly excellent results following gastro-enterostomy were explained by the improvement in the rate of emptying of the stomach, and the acid secretion accompanying ulcer in this situation was not of a character likely to lead frequently to after trouble. In duodenal ulcer the relatively high acidity which remained after gastro-enterostomy no doubt accounted for the troubles which sometimes followed, including secondary ulceration. The method, he said, yielded valuable information in cases where operation had not given a perfect result.

Exhibition of Cases and Specimens.

Dr. T. M. **BRIDE** showed four specimens of sarcoma of the choroid, two pigmented and two non-pigmented. He estimated their frequency as 1 in 3000 cases examined and asked for information from the members on the late results of these cases.

Dr. **CORSAR STURROCK** mentioned two cases where death occurred from secondary manifestations in the liver within two years after enucleation of the eyeball.

The **PRESIDENT** and Dr. **BOSDIN LEECH** described the case of a boy, aged 3, who had dullness of the left chest and dyspnœa of a stridulous kind. This continued for two and a half months, the temperature remaining normal, until the child died rather suddenly. Examination by Prof. Shaw Dunn revealed a minute piece of fish bone embedded in the right side of the larynx. There was perichondritis and absorption of cartilage cells. The afebrile course of the consequent bronchopneumonia was, they thought, remarkable.

Dr. **ARNOLD JONES** showed a case of cavernous hæmangioma of the vocal cord in a man 45 years of age. He removed the growth successfully by the indirect method. Dr. Jones remarked on the rarity of the condition, there being apparently not more than 73 recorded cases.

Mr. E. E. **HUGHES** showed some calculi found by chance in the bladder of a man of 65 at necropsy. Three of the calculi were of a curiously accurate mathematical shape, one consisting of a small round ball from which six long cone-shaped spikes projected.

Dr. **HILLYARD HOLMES** presented the kidneys from a case presenting signs which led to the diagnosis of "essential hæmaturia." Urinary bleeding was severe and the patient died in a uræmic state. At autopsy small granular kidneys were found, and Dr. Holmes remarked on this fact as being a likely explanation for many cases of so-called "essential hæmaturia." Dr. Holmes showed also a ruptured aneurysm of the middle cerebral artery in a non-syphilitic man of 38. —Prof. **SHAW DUNN** said that aneurysms were a commoner cause of cerebral hæmorrhage in young people than was generally recognised. They might occur in childhood, and he commented on the peculiar frangibility of the cerebral vessels as a class.

MIDLAND MEDICAL SOCIETY.

A MEETING was held in the Medical Institute, Birmingham, on Jan. 17th, Dr. C. E. **PURSLOW**, the President, being in the chair.

Exhibition of Cases and Specimens.

Mr. J. B. **LEATHER** showed a child of 12 who had lost a considerable part of both hands and one foot, as the result of syphilitic disease of the bone. The case was discussed by Mr. H. H. **SAMPSON**, who said that he had seen similar loss of tissue as the result of obliterative endarteritis.—Mr. L. **ROSE** thought that Raynaud's disease could not be excluded.

Dr. A. P. **THOMSON** gave the history of an obscure case of prolonged pyrexia, and showed a temperature chart (prepared in the manner suggested by Prof. Arthur Hall, of Sheffield) to illustrate the characteristics of the continued fever. The history was that of a previously healthy woman, aged 39, who, eight months ago, was seized with an illness which since had run a curiously intermittent course, corresponding with the intermissions of her temperature. While under observation in the hospital she had had bilateral effusion of blood in both pleural cavities, and the spleen and liver for a time had been enlarged and hard. Physical examination and all ordinary clinical methods had yielded nothing on which to base a diagnosis. The most suggestive feature was the relapsing nature of the fever. Dr. Thomson thought the case in all probability was one of Hodgkin's disease showing the Pel-Ebstein syndrome.—Dr. J. W. **RUSSELL**, for comparison, showed a chart of a case of Pel-Ebstein syndrome, which had died under his care.—Dr. **ALFRED PINEY** mentioned that Von Siegler described two cases of undoubted Hodgkin's disease, in which effusions of blood had occurred in the pleura and peritoneum, and he stated that in these cases it had been found that the effused blood showed a marked eosinophilia.—Dr. G. H. **MELSON** considered that in spite of negative blood cultures septicæmia could not yet be excluded.

Mr. **SEYMOUR BARLING** read a paper on Chronic Duodenal Ileus, and gave clinical histories of seven cases. In two of these the condition was caused by narrowing the duodenal lumen by the invasion of the wall of the bowel by growth or inflammation, whilst the symptoms of the other five were due to obstruction at the crossing of the mesenteric root and the superior mesenteric vessels. After pointing out the similarity in the symptoms of these two groups of cases, the relationship of the condition to the ætiology of acute gastro-duodenal ileus was considered. Diagnosis of the chronic condition could be made in a certain number of cases by a consideration of the clinical and radioscopic picture, but its mimicry of the symptoms produced by chronic appendicitis and gall-stones and chronic duodenal and gastric ulcer was often very close. The disease must be regarded as a clinical entity to be considered whenever a case of chronic indigestion was being investigated, and when laparotomy was performed in such cases the routine examination must include the third part of the duodenum and the site of crossing of the vessels.

The paper was discussed by Mr. L. A. DINGLEY, who showed a specimen of the condition which he had recently met with, and described two similar cases.

Dr. T. L. HARDY described the results of gastric analysis by the fractional test-meal method in some of Mr. Barling's cases. He stated that occasionally the diagnosis might be inferred from the chemical examination alone.

Mr. W. BILLINGTON considered that the slighter degrees of the condition were not rare, and stated that in his opinion the mobility of the right kidney was occasionally responsible for it.

BATH CLINICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING was held on Jan. 5th at the Royal United Hospital, Mr. W. G. MUMFORD, the President, being in the chair.

Mr. F. FRASER showed: 1. A case of old osteomyelitis in which the growth of the tibia had ceased, with the result that the fibula had outgrown and distorted the leg considerably. The orthopædic proceedings necessary to correct the deformity were described. 2. A child sent in as an acute abdomen; the case proved to be a double pneumonia and an acute pneumococcal peritonitis with complete recovery. 3. A case and specimen of abdomino-perineal removal of the rectum and sigmoid. The patient a month after the operation was remarkably well.

Dr. R. G. GORDON showed a case of malignant disease of the right testicle growing up the canal, and a photograph and X ray of nodes in an early case of rheumatoid arthritis.

Mr. A. L. FULLER showed a specimen of a left broad ligament dermoid with torsion of the omentum and separation of the tumour from the uterus by torsion.

Dr. W. P. KENNEDY showed an X ray plate of the cervical spine showing fracture of the body of the third cervical vertebra.

Dr. V. COATES showed a plate of the sella turcica in a case of acromegaly.

Dr. RAY EDRIDGE read a paper entitled

Romance and the Pharmacopœia.

The subject of the paper was the career of Dr. Thomas Dover (1660–1742), famous for his powder and notorious for his piracy on the Spanish Main. Dover's voyage round the world in his expedition captained by Woodes-Rogers is chronicled in the journal of the latter worthy and makes extraordinary reading when we consider the heads of the expedition were respectable members of society in their own country. Not the least interesting episode was the rescue of Alexander Selkirk from Juan Fernandez. Dover's quarrels with his fellow practitioners were endless. His science may have been questionable, particularly his predilection for quicksilver, "the greatest gift of God in the whole materia medica," but his popularity was considerable, and although his detractors' very names are dusty and forgotten, Dover himself still lives in the Pharmacopœia by reason of his powder.

Reviews and Notices of Books.

ŒUVRES DE PASTEUR.

Collected by PASTEUR VALLERY-RADOT. Vol. I.: Dissymétrie moléculaire. Pp. 480. Fr.50. Vol. II.: Fermentations et générations dites spontanées. Pp. 664. Fr.65. Paris: Masson et Cie. 1922.

THIS stately edition of the complete works of Pasteur forms a notable item in the celebration of the hundredth anniversary of his birth. Under the pious care of his grandson it will extend to seven volumes, of which the first two are now published. Volume I. contains some 45 memoirs of varying length and importance—some are brief notes—dealing with his early studies in crystallography and dating mostly from 1847–1857; there are as well a number of reports of committees of the Academy of Science on Pasteur's papers and similar varia, including the statement made by Lord Wrottesley when he was awarded the Rumford medal of the Royal Society of London in 1856. As is well known, Pasteur occupied the rest of his life in biological studies, always with a hankering after his early love. He went as far as to say, "I am convinced that life as we see it is a function of the dissymmetry of the universe or of the results which that entails," and as late as 1878 engaged in a project of putting together his classical work in chemical crystallography in the light of subsequent advances in knowledge. He wrote a preface and an introduction, which are here reproduced, but the book was drowned in his work on pathogenic bacteria, and never appeared. Volume II. reproduces about 30 papers written between 1857 and 1863 on alcoholic, lactic, and butyric fermentations, a series of 11 on spontaneous generation of 1860–1866, and a mass of "remarks," "replies," &c., on publications by Bastian and others on the same subject belonging to the period 1871–1879. Subsequent volumes will collect his studies on vinegar and wine, on silkworm disease, on beer, on infectious diseases, and on miscellaneous subjects.

The tale is told that when America went dry some of those who knew where to look went to the works of Pasteur for inspiration and practical help in their troubles—and not without reward. Let us hope that they found some of the pageantry of Pasteur's pilgrimage in their search for amateur alcohol. For a world of leisure with some room for quiet contemplation contains few more elevating experiences than to be absorbed for a while in the history of a great mind. And Pasteur's mind was materially productive as well; the mass of his writings is enormous, and it will indeed want leisure to apprehend their significance. Parts of the present volumes can easily be passed over; the controversies are not really intelligible in the absence of his opponents' writings, and Pasteur had not appreciated that to establish the truth of his own view he had to show only that he was right, not that the other man was wrong; he seems, indeed, to have shouldered the burden of rebuking sin without any great reluctance.

The editor has added a number of notes, almost exclusively of a bibliographical character. It would have added immensely to the value and interest of the collection if he could have got together a commentary on the substance of the papers, indicating where they stand in the history of the progress of knowledge. No one nowadays can have without guidance an expert appreciation of the detail of all the diverse topics with which Pasteur at one time or another concerned himself. A commentary would want a band of commentators, but the gain to the ordinary reader would be enormous. There happens to be in the last number of *Science Progress* (January, 1923, p. 386) an illuminating article by Mr. W. T. Astbury on the analysis of the molecular structure of crystals by X rays, in which the author points out that the methods of crystal analysis developed so wonderfully by Sir William Bragg and others in the last ten years fully confirms Pasteur's prophecies of 60 years ago and shows how far his fundamental work may be carried. The past, indeed, is of no interest in itself; without reference to the present we cannot even understand it.

ESSENTIALS OF CHEMICAL PHYSIOLOGY.

For the Use of Students. Eleventh edition. By W. D. HALLIBURTON, M.D., LL.D., F.R.C.S., Professor of Physiology in King's College, London. London: Longmans, Green and Co. 1922. Pp. 343. 8*s.* 6*d.*

WE cannot presume to introduce to our readers a book in its eleventh edition, on which so many of them have been brought up. This edition is thoroughly up to date and sound in every particular. Chemical physiology, called nowadays biochemistry or physiological chemistry, is really what the medical student wants; it is a branch of physiology in fact, and not of chemistry; it is physiology from the chemical standpoint, not the reverse. Accordingly, the book contains such theoretical matter as is desirable in approaching physiology from the chemical aspect. The practical exercises, printed in larger type, are well chosen to illustrate the subject in its close relation to the requirements of medical teaching, the applications of physical chemistry being neither forgotten nor given undue prominence. We have no suggestions or criticisms to offer; the book is good.

PRAKTISCHES LEHRBUCH DER TUBERKULOSE.

Second edition. By Prof. G. DEYCKE, Hauptarzt der Inneren Abteilung und Direktor des Allgemeinen Krankhauses in Lübeck. Berlin: Julius Springer. 1922. Pp. 301. 12*s.*

THE table of contents of this book gives the false impression that it follows the stereotyped lines of the conventional and orthodox text-book. First there is the inevitable historical review, followed by an account of the characteristics of acid-fast bacteria. There follows an account of tuberculosis as a national scourge, and statistics are given to show the extent of its ravages. Much other stock and standard information is given, and given lucidly and instructively. But the outstanding feature of this book, the thread running through the whole of it, is its advocacy of the system of partial antigens or partigens associated with the names of Profs. G. Deycke and H. Much. It is illustrative of the author's faith in this system that he recommends it even in renal tuberculosis—that hitherto uninvaded sphere of the surgeon. It is interesting to note that Prof. Deycke considers the spread of infection from one kidney to the other is by the blood-stream, although other authorities trace infection of the second kidney to ascent of tubercle bacilli from the bladder up the second ureter.

As regards treatment, the author claims that nephrectomy is being displaced by specific treatment, and in this field partigen treatment is definitely superior to plain tuberculin treatment. Indeed, it seems to be renal tuberculosis more than any other localisation of tuberculosis which has proved the value of partigen treatment. The author recommends nephrectomy only when there are signs of extensive suppuration, and even in such cases he considers specific treatment a necessary adjuvant. His statistics are not as rosy as his general conclusions. On p. 170 he tabulates the results of partigen treatment in 1761 cases of tuberculosis, chiefly pulmonary. There are 40 cases of urino-genital tuberculosis, only 6 of which rank among the "cures." This table does not show how many of these cases represent infection of the kidneys cured by partigen treatment, but on p. 258 the author refers to one severe case of renal and vesical tuberculosis in which a single course of partigen treatment effected a cure which was still maintained five years later.

Those interested in partigen treatment should consult this book, which gives a first-hand account of its rationale and technique. The author's enthusiasm for it is great, and it is not marred by that praise of self and abuse of others which too often produces prejudice against tuberculin therapy.

THE TREATMENT OF ACUTE INFECTIOUS DISEASES.

Second edition, revised. By FRANK SHERMAN MEARA, M.D., Ph.D., Professor of Clinical Medicine in the Cornell University Medical College. New York: The Macmillan Company. Pp. 806. 31*s.* 6*d.*

Prof. Meara's book has many original features. It is an exhaustive treatise on the therapeutics of the infectious diseases and at the same time is admirably designed for rapid reference. At the cost of a considerable amount of repetition in the description of methods of treatment applicable to more than one disease, the chapter on each fever is presented as a complete whole, with a minimum of cross references, and, moreover, a full summary of contents is appended. This lavishness, though convenient, is a little overdone. Thus in the section on "Grip," the same prescription appears twice written out in full, once in the chapter itself, and once in the summary.

Beginning with a short summary of the main principles of the treatment of fever, Prof. Meara next deals at some length with the question of dietetics. His recommendations are suggestive, and cannot fail to be of use to the practitioner. The infective conditions included in the book number no less than 44, and include diseases which are not, as a rule, classed among the infectious diseases in this country. For instance, tonsillitis, tracheitis, and pleurisy, as well as pneumonia and rheumatic fever, are discussed in detail. The serum treatment of pneumonia is described at length, and full directions are given for dealing with the various complications of the disease. For the diet in typhoid fever Prof. Meara strongly advocates the free use of carbohydrates, and considers milk-sugar the most suitable form in which to give them to make up any deficiency. He also believes firmly in hydrotherapeutic measures and the use of the cold bath. He obviously has little enthusiasm for vaccines in this fever, but speaks not unfavourably of their intravenous administration in doses of from 25 to 50 millions. Prof. Meara appears to lay as much stress upon the dangers of circulatory failure in scarlet fever as in diphtheria. The vasomotor stimulants on which he most relies are camphor and caffeine, the latter particularly in emergencies, and he appears to depend on digitalis more than many in this country would be inclined to do. He has a good word for adrenalin, but regards alcohol as useless in circulatory failure; this attitude seems to be very general among American physicians. He is an enthusiastic supporter of open-air treatment; in his view cold air playing on the face has a reflex stimulant effect, and this treatment can be trusted to raise the blood pressure more effectively than any drug will do. The dosage of antitoxin is fully discussed, and the author's recommendations are much the same as those of the Board of Health of New York. For mild cases 3000 to 5000, for more severe 5000 to 6000, and for malignant 15,000 to 20,000 units are advised, these doses to be repeated if necessary. A short section on intubation, contributed by Dr. Miner C. Hill, while sufficient for students, is hardly full enough to satisfy those who have had real difficulties with retained tubes. The chapter on cerebro-spinal fever is excellent; we note that W. Herrick's method of supplementing intrathecal by intravenous injections is advised.

Prof. Meara's book is of great practical value, the different methods of treatment being most judicially discussed, while the author has the courage to give his readers a definite lead. The numerous prescriptions will be found useful, no drug being mentioned without the appropriate dose being indicated. The reader will find much more in these pages than therapeutics. The full consideration of that subject entails the discussion of many pharmacological and pathological questions, and, as all the complications of the individual diseases are also fully dealt with, there is a mass of varied information which makes the volume very easy, and always interesting, reading.

FOOD, HEALTH, AND GROWTH.

A Discussion of the Nutrition of Children. By L. EMMETT HOLT, M.D., LL.D., President Child Health Organisation; formerly Professor of Diseases of Children in the College of Physicians and Surgeons, Columbia University, New York. London and New York: Macmillan Company. 1922. Pp. 273. 7*s.* 6*d.*

ALTHOUGH there are already so many good books, and not a few bad ones, dealing with this subject, the present little volume will, we feel confident, make and maintain for itself a place in the literature. Written for the general reader, it gives none the less the results of the latest researches in an excellently clear manner, and will be found really interesting reading. It is a thoroughly sound and wise book by one who knows all that matters about his subject. Many writers on this and kindred subjects would do well to imitate this author's method of presenting dietetic facts without innumerable tables which few have the industry to consult properly. The author gives tables of caloric values of common foods in an appendix.

HEREDITY AND INSANITY.

Vererbung und Seelenleben. By Dr. H. HOFFMANN, Privatdozent, Tübingen University Neurological Clinic. Berlin: Julius Springer. 1922. Pp. 258.

THIS is an attempt to examine heredity and familial incidence in various forms of insanity and nervous disease. The book has three prominent characteristics. First, and most valuable, is its analectic and bibliographical method: the widespread literature of the subject is well collected. Secondly, a compliment is paid to E. Kretschmer's work, in that his preoccupation with "schizothymic" and "cyclothymic" types of mentality, both normal and pathological, is endorsed and imitated. In the third place, too great persistence is shown in submitting the material to Mendelian analysis, for data of human inheritance are usually much too inexact to warrant such a procedure, or at least to afford reliable inferences therefrom. Many pedigrees are collated at length. The student of pathological heredity should not fail to look through this book, or he may miss some interesting war-time foreign papers on this subject.

JOURNALS.

JOURNAL OF PATHOLOGY AND BACTERIOLOGY. Vol. XXVI., No. 1. Pp. 1–136. January, 1923.—The Relation of Vitamin C to Bacterial Infection, by G. M. Findlay (Edinburgh). Guinea-pigs with an inadequate amount of antiscorbutic in their food and suffering from a chronic form of scurvy are less resistant than normal animals to experimental pneumococci, streptococci, &c., which the author attributes in part to the degenerative changes found in the bone-marrow.—Complement Fixation in Liver Fluke Infection, by N. H. Fairley and F. E. Williams (Melbourne). Infection of sheep with *Fasciola hepatica* may be diagnosed in about three-quarters of the cases by serological tests against extracts of flukes.—The Pathology of Schistosomiasis in Man, by H. R. Dew (Melbourne). Working with material collected in Egypt the author describes the similarities and differences between infections with *S. hæmatobium* and *S. mansoni*.—A Case of Symmetrical Cortical Necrosis of the Kidneys in an Adult Man, by J. Bamforth (London). This well-known but rare condition has hitherto been found only in women.—The Development of Deeply Pigmented Bodies as a Further Stage in Fatty Change in Cell Degeneration, by E. Emrys-Roberts and H. A. Haig (Cardiff).—A Differential Medium for Streptococci, by H. W. Crowe (Harrogate). An illustrated summary of the diagnostic features of different varieties of streptococci grown on the author's "chocolate" medium.—The Desiccation of Serum and Other Proteid Solutions, by P. Hartley, A. J. Eagleton, and C. C. Okell (London). Normal and immune sera can readily be dried and preserved with little if any loss of their specific properties. The satisfactory character of the dried complement is further attested in another paper by C. H. Browning and E. M. Dunlop (Glasgow).—The Relation between Appendicitis, *Oxyuris vermicularis*, and Local Eosinophilia in the Appendix, by the late E. H. Eastwood (Sheffield). *Oxyuris* is often found in the appendix, but it has nothing to do with appendicitis. In an interesting *quantitative* examination of the local leucocyte reaction in appendicitis the author shows that there is at first a sharp increase of neutrophiles, reaching its maximum on the second or third day and subsiding in about 10 days, at which point the eosinophiles reach their maximum and remain far above normal for a month or more.—Foreign Body Tubercles on the Serous Coat of the Stomach Caused by the Escape of Particles of Oat Seed, by T. Shennan (Aberdeen).—Herpetic Encephalitis in Rabbits, by C. Da Fano (London). A long account, with many illustrations and a bibliography of 67 items, of the changes in the brains of rabbits infected with the virus of labial herpes by Dr. J. R. Perdrau. The changes are very analogous to those found in natural and experimental lethargic encephalitis. The "minute bodies" are fully described and figured and cautiously identified with the virus.—Tomato Extract as a Culture Medium, by C. E. Jenkins (Manchester). The meat of ordinary culture media may be replaced by tinned tomatoes.—On Making Dilutions of Antisera, by J. S. C. Douglas (Sheffield). It is necessary to wash out a pipette an extraordinary number of times before one can be sure that all traces of serum have been removed.—The Serum Constituents responsible for the Sachs-Georgi and Wassermann Reactions, by T. J. Mackie (Cape Town). The two reactions depend on protein fractions which can be separated from one another, and are therefore independent.—Alterations in the Characters of *Streptococus mucosus* and Pneumococcus *in vivo*, by C. H. Browning and R. Gulbransen (Glasgow). The slimy character of *S. mucosus* is largely lost in mice. Very minute doses of highly virulent pneumococci may give rise to chronic septicæmia in mice lasting several weeks.—The Influence of *B. coli* on the Growth of *B. typhosus* in Brilliant Green Media in Typhoid Carriers, by R. P. Smith (Glasgow). The stools of typhoid carriers may contain strains of *B. coli* which inhibit the growth of the typhoid bacillus in a very definite way.—A Case of Plasma-Cell Myeloma. by A. F. B. Shaw (Newcastle). A solitary tumour of the humerus without Bence-Jones albuminuria.—The Effect on the Liver of Coal Tar Applied to the Skin of Rabbits, by J. Davidson (Edinburgh). In acute cases degeneration and necrosis succeeded in chronic poisoning by cirrhosis and nodular regeneration.—Peroxide Formation by Bacteria, by J. W. McLeod, J. Gordon, and L. N. Pyrah (Leeds). *Bacillus bulgaricus* and *B. acidophilus* produce hydrogen peroxide.—Inhibition of Opsonic Activity in Tuberculosis and a Modified Opsonic Technique, by S. L. Cummins and C. M. Acland (Cardiff). Using the percentage of active leucocytes as an index the authors describe "zones of inhibition" which are revealed by working with different dilutions of serum.—A Method of Performing the Wassermann Reaction Without the Use of Alien Complement, by A. Gough (Leeds).—Observations on Tularæmia, by J. C. G. Ledingham (London). The minute organism is difficult to cultivate and the strain is best carried on by guinea-pig passage, in doing which three members of the staff of the National Collection of Type Cultures have already become infected. When it can be detected in the tissues of animals it is present in enormous numbers and an emulsion of the spleen of infected mice can be used for diagnosis in man by agglutination.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 3, 1923.

ALCOHOL AND INSANITY.

THE danger of mistaking proof of mere antecedence for proof of causal influence is strikingly shown in the exaggerated beliefs that have long been current with regard to the rôle of alcohol in the causation of insanity. Alcoholic excess is tolerably widespread in the community, and is therefore likely to be of common occurrence in persons who become insane; it is, moreover, a condition which is fairly easily ascertained in a patient's history. It accordingly bulks very largely amongst the alleged causes of insanity in asylum tables; and through the uncritical acceptance of the data in these tables as evidence of causal relation and not of simple coincidence, alcoholic intemperance has come to be considered as a peculiarly important ætiological factor in insanity, whatever be the clinical form of the disease. Thus we find it confidently laid down in text-books of psychiatry that alcohol stands in the first rank as a factor in the production of insanity, and statistical precision has been given to a similar though less extravagant view in official reports which assert that intemperance is the assigned cause of mental disease in 22·7 per cent. of the cases of male patients and in 9·4 per cent. of the cases of female patients admitted to asylums in England and Wales. These estimates have not, of course, escaped criticism. Sir FREDERICK MOTT, in particular, has drawn attention to the unreliability of the asylum evidence in their support, and to the extent to which it is vitiated by the personal equation of the medical officers who record, and of the friends who furnish, the details of the patients' histories and habits. And he has reinforced this destructive criticism by the remarkable results of pathological research at Claybury Asylum and Charing Cross Hospital, which showed that the morbid conditions characteristic of chronic alcoholism were relatively rare in the bodies of the insane, and when met with were almost always found in cases which in life had presented the clinical features of the distinctively alcoholic psychoses, such as Korsakow's disease and alcoholic dementia, while, on the other hand, the cases of advanced cirrhosis of the liver amongst hospital patients rarely exhibited any mental symptoms. And other investigators, approaching the question from a different angle, were led to adopt a similar attitude of scepticism, when they observed that a comparison of alcoholism and insanity in respect of their regional distribution in this country showed a complete absence of correspondence between these two phenomena. They found, moreover, that the proportion of cases of insanity ascribed to intemperance was in many instances conspicuously high in areas where there was least chronic alcoholism, though it is presumably the chronic intoxication which should mainly produce disease of mind. Such cases were notably frequent where the insanity rate was lowest, though an added alcoholic influence might be expected to raise that rate.

From such facts it was difficult to draw any other inference than that the influence of alcoholism as a cause of certifiable insanity was very much less than had been alleged, and that it was limited to the relatively small group of disease forms exhibiting characteristically alcoholic features in the clinical picture—that is to say, delirium tremens, Korsakow's disease, Eifersuchtwahn, and alcoholic dementia. This conclusion has been confirmed in a very striking way by the evidence obtained during the war in this and other countries where restrictive liquor legislation and shortage of the food materials used in brewing and distilling brought about a rapid and extreme reduction of alcoholism. In a letter published in THE LANCET of Sept. 23rd, 1922, Dr. W. C. SULLIVAN, medical superintendent of Broadmoor State Asylum, pointed out that under the influence of these conditions, intemperance, as measured by convictions for drunkenness, deaths from chronic alcoholism and from cirrhosis of the liver, and cases of attempted suicide, had decreased by about 80 per cent. from 1913 to 1918, but that, despite this enormous reduction of alcoholism, the number of first admissions of women to asylums in England and Wales showed no decline, but on the contrary a slight increase. The facts regarding the male population pointed to a similar conclusion, but here the disturbing influence of the withdrawal of large numbers of men of military age from civilian life might have been suggested to be a factor qualifying the value of the statistical comparison. The evidence which has recently become available from the enemy countries is in striking agreement with these facts of English experience. Thus in a very fully documented paper [1] J. PERETTI (Düsseldorf) gives figures showing that in the large asylums and clinics in Prussia there was in 1918 as compared with 1913 a decrease in the number of alcoholic patients amounting to 87 per cent. in the case of males and to 78 per cent. in the case of females. The distribution of this decrease over the several forms of alcoholic psychoses was as follows: In males a decrease of 93 per cent. in delirium tremens, of 87 per cent. in the allied conditions of acute alcoholic hallucinosis, of 90 per cent. in chronic alcoholic degeneration, and of 68 per cent. in pathological drunkenness (Rauschzustände); in females, a decrease of 89 per cent. in delirium tremens, 83 per cent. in hallucinosis, 76 per cent. in alcoholic dementia, and 69 per cent. in pathological drunkenness. But this enormous diminution in the definitely alcoholic psychoses was not associated with any corresponding effect on the frequency of the ordinary forms of insanity. To test this point PERETTI compared the movement of the two classes of psychoses as shown by the returns published in the Prussian official statistics from 1913 to 1916—the latest date for which information was available. He found that, while there was a decrease in 1916 of 26 per cent. in the number of admissions for non-alcoholic psychoses in men—apparently due in large part to the decrease of the male civilian population through the demands of military service—the reduction in admissions for alcoholic disorders amounted to 73 per cent.—that is to say, was nearly three times as much as the diminution in the ordinary forms of insanity. And in women, where the disturbing influence of army service was absent, the figures showed a complete parallel with the results recorded in England, a decrease in the alcoholic psychoses of 56 per cent. being accompanied by an actual though slight (1·4 per cent.) increase in the non-alcoholic types of insanity. K. BONHOEFFER (Berlin), W. SCHNEIDER (Cologne), and other observers, dealing with statistical material from individual provinces in Germany, have arrived at the same results; while WAGNER-JAUREGG has recorded evidence to the same effect from Austria.

---

[1] Allgemeine Zeitschrift für Psychiatrie, 1921–22.

Thus it will be seen that the results of the mass experiment of the war have completely confirmed the view that intemperance is not to be regarded as an important factor in the general causation of mental disease, and that, in fact, the only insanity produced by alcohol is alcoholic insanity—that is to say, those definite and well-recognised forms of mental disorder which present the specific clinical characteristics indicative of their alcoholic origin. In other forms of insanity, in paranoia, for instance, or in dementia præcox, there may, of course, in many cases be a history of hard drinking; but the only legitimate inference from the fact is, not that alcohol produced the mental disorder, but merely that it failed to prevent its development. These considerations, it should be noted, apply only to the connexion of alcoholic excess and insanity in the individual drinker; they do not touch the question of the possible rôle of parental alcoholism in the causation of degenerative mental disorders in the offspring. In regard to this there is positive evidence of considerable cogency, reinforced indirectly by the results of animal experiment and pathological observation. Through this indirect mode of action alcohol may make a very serious contribution to the burden of insanity; and even if this were not the case, the part which it takes in the causation of crime and of suicide and in the production and aggravation of physical disease would be sufficient to constitute intemperance a grave danger to the well-being of the community. But it is not necessary to load the indictment against an admitted evil by exaggerating its pernicious influence, as is done when alcohol is asserted, in its immediate action, to be one of the chief factors in the causation of mental disease. We may have long to wait for much positive knowledge regarding the ætiology of insanity, but the obscurity of the problem is diminished by the dissipation of erroneous doctrine.

◆

THE GENERAL MEDICAL COUNCIL AND THE D.P.H.

THE new resolutions and rules drawn up by the General Medical Council for Diplomas in Public Health have now been embodied in the regulations for obtaining this diploma, and will come into force on Jan. 1st, 1924. They involve far-reaching alterations both in the curriculum and in the time at which this diploma can be obtained, and these are likely to influence very adversely the number of candidates entering for it. The first most notable alteration is that no candidate can be admitted to Part II. of the examination until he can produce evidence of having been in possession of a registrable qualification in medicine, surgery, and midwifery during not less than two years, and of having completed the curriculum for the diploma extending over a period of 12 calendar months subsequent to the attainment of a registrable qualification. The second important change is that the candidate must produce evidence of having been engaged during a period of not less than six months in acquiring a practical knowledge of the duties, routine and special, of public health administration under the supervision of a medical officer of health, and of having received from such officer or other competent medical officer during not less than three hours on each of 60 working days practical instruction in those duties and also those relating to (*a*) maternity and child welfare service, (*b*) health service for children of school age, (*c*) venereal diseases service, (*d*) tuberculosis service, (*e*) industrial hygiene, and (*f*) inspection and control of food, including meat and milk. This certificate must be obtained from a medical officer of health who devotes his whole time to public work, or from a medical officer of health of a sanitary area having a population of not less than 50,000, or, in Ireland, from the medical superintendent officer of health of a county or county borough having a population of not less than 50,000.

It is probable that the effect of the first of these changes, whereby a period of at least two years must elapse after qualification, of which only one need have been devoted to the study of public health (since the curriculum is fixed at 12 calendar months), will be to limit this diploma practically to those proposing to enter the public health services. It may be presumed that this was the intention of the General Medical Council, since it is difficult to see any other reason for this rule. Even if we assume that it is hoped that the extra year will be spent in hospital appointments or in special studies connected with public health matters, the regulations do not enforce anything of the sort, and the candidate may use this year in any way he desires. If it be supposed that the intention is to secure a highly-trained and specialised type of medical practitioner for the public health services, the regulation may deprive these services of some men of outstanding ability but limited means, who may be unable to devote two extra years, after the long course necessary for qualification, in order to take a diploma, with only the chance of securing some whole-time appointment afterwards. An even more serious aspect of these changes, in our opinion, is the hardship imposed on at least three classes of medical men for whom a special knowledge of public health and hygiene is a useful, indeed a necessary, possession. The first class comprises officers in the Royal Army Medical Corps. Both in peace and in war time their duties demand a thoroughly practical knowledge of these matters, and although they will doubtless receive from the army authorities instruction in hygiene and preventive measures, they are now to be deprived of the possibility of attending the curriculum and obtaining the diploma, which many have been able to secure. Hitherto, work done under a sanitary staff officer of the Royal Army Medical Corps, having charge of an Army Corps, District or Division, has been recognised by the General Medical Council. By the new regulations, such work will no longer count as part of the curriculum. A second example of hardship would be the case of a newly-qualified practitioner taking up medical duties in a colony in a tropical or subtropical region the "tour of service" of which is four years. Unable by the regulations to take the diploma before starting his duties, and anxious to try for it on his first leave, he may perhaps be granted an extra six months' study leave in addition to his ordinary health leave of eight months, making 14 months in all. Allowing two months for his journey home and back to duty, he would have to devote the whole of the remaining 12 months to the curriculum, leaving no time for real holiday, which his health would in all probability demand. A further disadvantage is that the habit of study and the facility for examination are often materially altered by an interval devoted to ordinary duties, and it would probably require some determination and strength of character to face the work entailed after four years' service, perhaps in an unhealthy and unfavourable climate. Thirdly, Indian and Colonial students qualifying in this country are also likely to be inconvenienced by the extra year demanded after qualification. This is certainly regrettable: the home country has always taken a prominent part in the development of the science of public health, and it is much to be desired that students from all parts of the Empire should be encouraged to pursue their studies in hygiene here as well as in their native lands.

Still further difficulties are placed in the way of Indian and Colonial aspirants for this diploma by the second regulation, to which we have drawn attention. It would seem that instruction given by a sanitary officer in India, in the British Dominions, and the Colonies will not be accepted, since the Committee of Management of the Examining Board in England of the Royal Colleges of Physicians and Surgeons has been informed that the whole course of training under a medical officer of health, to cover all the subjects mentioned in this paragraph, must be carried out under one and the same officer in one and the same area. The list of subjects is such that it is unlikely they can be studied together elsewhere than in this country. We venture to hope that representations may be made to the General Medical Council with a view to some modifications in these regulations, so that the hardships and restrictions to which we have drawn attention may be removed.

THE PREVENTION OF HEART DISEASE.

As progress is made in our knowledge concerning the causes of disease, the importance of adopting effective preventive measures becomes more and more evident. In the case of tuberculosis this has already received ample recognition, but in heart disease we are still inclined to devote most of our attention to remedial treatment. Not only in simple rheumatic cases but also in malignant endocarditis, a disease in which so many different lines of treatment have met with so little success, must we look to prevention as the most likely source to yield more satisfactory results. Three articles on heart disease appear in the present number of The Lancet. They deal with very different aspects of the subject; but all three point to the same conclusion—the fundamental importance of preventive measures.

The statistics of Drs. J. Cowan and J. K. Rennie show that out of 49 fatal cases of chronic valvular disease, in which the cause of death appeared to be primarily cardiac, in 39 an acute endocarditis was found at autopsy. From these figures it would appear that myocarditis, associated with acute reinfection of the cardiac valves, is one of the commonest causes of death in such cases. The writers suggest that, in order to prevent reinfection of valves which are the seat of chronic endocarditis, it is not sufficient merely to eradicate any source of sepsis, but that an effort should be made to keep the patient continually fit, by submitting him to what practically amounts to a very mild form of continuous athletic training. Dr. F. J. Poynton would carry the argument a step further. He records an extremely interesting series of cases which appear to form connecting links between simple and malignant endocarditis. He maintains that, in one type of the latter disease, the causative organism is either identical with, or closely allied to, that which is responsible for rheumatic infection, and that such cases are examples not of superadded infection on a previously damaged valve, but rather of the reawakening in a more virulent form of organisms which for a time have remained dormant. In this connexion there arise two extremely difficult problems. How far are we justified in classifying all cases of acute endocarditis of obscure origin as rheumatic? And in such cases how are we to ascertain when the healing process is complete? In the present state of our knowledge the answer to the first of these questions can hardly be conclusive. For even an associated polyarthritis, although closely resembling true rheumatism, is not necessarily rheumatic, whereas when endocarditis is the only sign, the evaluation of its significance is still more difficult. From the practical aspect of treatment the second question is of even greater importance. Clinical manifestations, such as the disappearance of an apical diastolic murmur referred to in Dr. M. O. Raven's paper, may be highly suggestive that healing has taken place, but in many cases the evidence is insufficient to justify us in coming to a definite conclusion. This state of uncertainty is by no means satisfactory. The problem is one of far-reaching practical importance and calls for further investigation. From the economic standpoint rheumatic heart disease is one of the most important causes of wastage in man-power, owing to the frequency with which it gives rise to total or partial incapacity during the productive years of life.

There may be some who will not admit the existence of a rheumatic malignant endocarditis, but even so the frequency with which organisms attack valves previously damaged by rheumatism, and the large percentage of cases of chronic valvular disease in which reinfection or reawakening of infection, as the case may be, is directly responsible for the fatal issue, cannot but give us cause to hope that some effective preventive measures against simple rheumatic carditis will lead to a considerable diminution in the incidence of the more serious condition. Complete and prolonged rest is the essential element in preventive treatment. The required duration of this rest can only be ascertained by a large series of careful clinical observations. That there should be available greater facilities both for treatment and for observation of such early cases is an urgent necessity at the present time.

THE AFTER-EFFECTS OF EPIDEMIC ENCEPHALITIS.

In the course of the initial investigations carried out in 1918 by the Local Government Board and the Medical Research Council into epidemic encephalitis, certain manifestations, such as an alteration in the mental condition, residual cranial nerve palsies, athetoid movements, and paresis were observed in a limited number of patients who, in other respects, had recovered from their attacks of illness; a guarded opinion was expressed as to the possible risk of after-effects in the disease.[1] Unfortunately, this warning has been fully justified and accentuated in the progress of time by further observations. In the representative examples of juvenile cases, exhibited at a meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine on Jan. 26th, and reported in our present issue, the crippling and serious effects that may ensue on acute epidemic encephalitis were demonstrated and the subsequent discussion emphasised that the "new disease" brings in its train sequelæ both of neurological and medico-legal importance. At the same time a work by Dr. Gabrielle Lévy[2] reaches us, embodying her researches in the service of Prof. Pierre Marie at the Salpêtrière. Dr. Lévy has investigated 129 cases of after-effects,

[2] Lévy, G.: Contribution à l'étude des manifestations tardives de l'encéphalite épidémique. Paris: Vigot Frères. 1922, Pp. 314.

77 of which occurred in females. All ages were considered from three cases below 10 years of age to two cases above 60 years. Seventy cases exhibited the condition known as symptomatic paralysis agitans or the Parkinsonian syndrome; this, therefore, was the preponderating type in the series. Forty-three cases were classified as "excito-motor"; cases in this group showed choreiform movements, myoclonus and hiccup, bradykinesia and localised movements of the face. One case exhibited the remarkable spasm of torsion resembling spasmodic torticollis; ten cases of the respiratory form were collected, one case of hemiplegia, and four cases of post-encephalitic obesity. Dr. Lévy gives an excellent description of the types and a detailed account of the associated signs and symptoms which she has studied and sub-classified with care. Sixty-eight cases are recorded in detail. In a pathological section, the author has investigated four fatal cases of the Parkinsonian syndrome and finds that inflammatory lesions may be still active, especially in the mesencephalon and in the neighbourhood of old lesions due to acute encephalitis. This discovery accords with the work of Levaditi, Harvier, Netter, and Durand concerning the prolonged persistence of the virus of encephalitis.

The manifestations of the after-effects of epidemic encephalitis may be grouped: (*a*) into those appearing in the course of the original acute malady and persisting after partial or complete disappearance of all other symptoms; and (*b*) those which ensue after the original acute malady has apparently terminated, or, in some cases, has passed unrecognised. Such effects are declared after a latent period of extreme variability ranging from some weeks to over two years. In one or two cases reported by Dr. Lévy the after-effects cleared temporarily but reappeared some months later. No definite opinion, therefore, can be expressed until after the lapse of some years as to whether an attack of acute encephalitis, however mild in appearance, may or may not result in serious sequelæ. The great frequency of the Parkinsonian syndrome is a marked feature in the continental literature; it is difficult to affirm at present whether this preponderance also obtains in this country, owing to the fact, as stated by Dr. C. P. Symonds at the discussion, that the acute illness passes unrecognised and un-notified in many cases. Once declared, however, the late manifestations cannot be overlooked. Fewer instances of disease are more pathetic than the juvenile cases of paralysis agitans, now familiar to the neurologist, since 1919; and alike in children and adults the Parkinsonian syndrome must be regarded as the gravest of sequelæ. At all ages mental symptoms complicate the clinical picture, and we do not yet know whether the syndrome merges into the classical chronic disease, previously solely observed in elderly adults. Prof. Marie and Dr. Lévy, whilst admitting many points of resemblance, lay stress on certain points of distinction of which the slow evolution of the malady and the age of the patient in paralysis agitans, perhaps, are the more important. Souques, however, at the Congress conducted by the Société de Neurologie de Paris in June, 1921, maintained the identity of the two forms of disease. With regard to the excito-motor sequelæ, Dr. Lévy points out the rhythmical character of many of the movements, the marked incidence of hypertonus, the distinctions between bradykinesia and myoclonus, and the inhibitory influence of sleep upon these phenomena. The duration of this group of after-effects is variable, but appears to be always long; some movements, such as bradykinesia, seem to disappear in the course of one to two years; in certain patients myoclonus has persisted for over four years. Of still graver significance is the fact that any of these movements may develop into symptomatic paralysis agitans.

The protean manifestations of the post-encephalitic state have not yet been exhausted, but brief allusion can only be made here to the local sequelæ, such as hypertonus, paresis, hemi-paresis, subjective sensory symptoms, trophic changes, the cases resembling disseminated sclerosis, described by Souques and others, and the curious respiratory spasms of which Dr. H. C. Cameron showed a good example at the recent meeting. Occasionally, true Cheyne-Stokes respiration has followed on epidemic encephalitis. It is important that attention should be directed to the mental after-effects of the disease which, in all probability, are dependent upon cortical lesions; they occur both independently of, and in association with, the after-effects previously mentioned. Irritability, maniacal outbursts, hebetude, complete change in moral character and self-control, lying and theft, may appear for the first time in the victim of encephalitis, as well as grosser mental defects, which result in the patient's rapid transference to an asylum. In the former class of case the patient may commit offences which render him amenable to legal punishment, and the medico-legal significance of these manifestations cannot be over-estimated. Hitherto, both in this country and abroad asylum control has appeared to be indicated in all severe examples. It will be noted that the experience of Dr. F. C. Shrubsall, in the London County Council schools, leads to a more hopeful view of the juvenile case; he finds that if the child is placed in a suitable environment and under special educative influences the majority of the milder types of mental defect resulting from acute epidemic encephalitis can be permanently cured.

◆

ZINC POISONING.

A sudden outbreak of illness occurred recently amongst the inmates of a large institution near London which indicates the danger which may arise from the use of galvanised iron vessels for cooking purposes. About 400 persons were served at tea with hot stewed apples. The remainder of the meal consisted of bread and margarine and tea. Within a few minutes more than 200 of those who partook of the stew complained of dizziness, sickness, or a feeling of sickness, colic, and tightness in the throat. There was some diarrhœa, but no double vision. The medical officer at once administered doses of bismuth and chalk mixture, and within a short time most of the sufferers had recovered and were able to take supper at 7.45 p.m. Only 10 persons were at all seriously ill, and all of them were able to carry out their ordinary work next day, so that obviously the effects of the poisoning soon passed off. The apples were freshly gathered and were stewed in large galvanised iron "skeps" which were placed in iron steamers. The skeps were used because it had been found on a previous occasion that the apples became black if placed directly in the steamers. A chemical examination of some of the stewed apples remaining over from the meal showed that they contained 7 gr. of zinc expressed as zinc oxide per pound—this being equivalent to 25 gr. of hydrated zinc sulphate to the pound. The emetic dose of zinc sulphate is 10–30 gr. and each person consuming the stew may be assumed to have taken 18–20 gr. of sulphate of zinc.

It is well known that vegetable acids are prone to act on metals, and the cause of the outbreak in question hardly seemed in doubt from the first. But expert scientific opinion states that vessels of galvanised iron should never be used for containing food materials in view of the solvent properties which many of these possess for zinc. It seems well that the general public should be aware of this fact.

Annotations.

"Ne quid nimis."

JENNER CELEBRATION IN PARIS.

A STRIKING appreciation of the work and life of Edward Jenner was manifested in the ceremony held last week by the Académie de Médecine. On Jan. 23rd a *séance solennelle* was devoted to honouring the memory of the discoverer of vaccination. The Council of the Academy marked the importance of the occasion by wearing the richly embroidered court suit with cocked hat and sword, and the Government signified its interest by the presence of Mr. Strauss, the Minister of Hygiene. The international entente was also marked by the presence of the First Secretary of the British Embassy, replacing Lord Crewe, who was detained by other duties. After the opening remarks of the President, Prof. Chauffard, a communication on the history of vaccination was made by Dr. Camus, director of the Institut Supérieur de Vaccine. Dr. Pierre Teissier followed with an address demonstrating the benefits secured since *la méthode de Jenner* had become obligatory. Thus, while small-pox had claimed numerous victories during the war of 1870, this terrible disease was almost unknown in the French armies during the late war. Dr. Jeanselme followed with a record of the introduction and results of vaccination amongst the natives of French colonies. Striking results had been obtained even in the absence of sanitary improvements, the natives being won over by the instruction of native doctors in the technique. The Secretary of the Academy, Prof. Achard, then read a long list of addresses, messages, and warm expressions of admiration sent from all parts of France, as well as from Belgium, Switzerland, Holland, Italy, and Spain. Most European countries were represented, while the Bey of Tunis had sent his own physician. The delegate from the Royal Society of Medicine, Sir StClair Thomson, gave a short address in French, returning thanks for the honour paid to British medicine and rendering homage to Pasteur as the connecting link between the work of Jenner and Lister. He remarked that "sans Pasteur, Lister serait resté inconnu. Sans Jenner, ce médecin de campagne, qui sait—le grand œuvre de Pasteur serait, peut-être, resté stérile?" The President accepted the gift of a proof engraving of Hobday's well-known painting of Jenner, offered by Dr. Walter S. A. Griffith, who presented the original to the Royal Society of Medicine. The meeting concluded with a lantern demonstration of pictures of Jenner and scenes associated with his life, many drawings being shown—artistic as well as humorous—connected with the introduction of vaccination. In another room of the house of the Academy there was an exhibition of other Jenneriana. In the evening a dinner was given by the President and Council of the Academy to the foreign delegates and visitors, Mr. Strauss being seated on one side of the President and the First Secretary of the British Embassy on the other. After dinner speeches were delivered by Sir Almroth Wright, Sir Ronald Ross (delegate of the Royal Society), and Dr. R. O. Moon (delegate of the Royal College of Physicians of London). The occasion was noteworthy for the whole-hearted honour paid to Jenner, the appreciation of his life and character as well as his work, and the cordial and sincere affection shown to his country and his compatriots.

A WASSERMANN MICRO-TECHNIQUE.

IN the current number of the *British Journal of Dermatology and Syphilis* appears an article from Dr. R. Donald on a micro-determination of the Wassermann reaction. The results obtained by this method are closely comparable to those obtained by the ordinary Wassermann test. Details of his original technique appeared in THE LANCET[1] in 1916; it is a one-tenth scale transposition of the well-known method of McIntosh and Fildes. The author rightly points out that one of the chief assets of his technique is the small amount of serum required for each test, a fact which makes the method of great value in the examination of infants. In addition, the use of easily calibrated drop pipettes for measuring the various ingredients of the test save much labour and time. In the present communication further evidence is produced of the value of the micro-method as a time-saving device. It is pointed out that owing to the very small quantity of complement required in the test, the same guinea-pig can be used as a supply of complement for many months. During the whole of this period the complement content of the guinea-pig serum was found to remain constant, a fact which allows the author to dispense with the routine titration of complement as a preliminary to the test proper, as only the initial determination of the titre of the complement is necessary.

THE HYGIENE OF COWSHEDS.

A REPORT prepared for the public health and housing committee of the West Riding County Council has just been issued by Dr. J. R. Kaye. The report is of particular interest in showing means by which county councils, in spite of their lack of direct statutory powers in regard to cowsheds and dairies, may nevertheless exercise a far-reaching and beneficent influence on the supervision of milk-supplies. The question of a pure milk-supply was before the sanitary committee of the county council in its earliest days; the sanitary surveys of the Riding which were begun in 1895 revealed a great deal of apathy amongst local authorities with regard to their duties in connexion with the lighting, ventilation, drainage, &c. of cowsheds—duties placed upon them by the Dairies, Cowsheds, and Milkshops Orders and Regulations of 1885 and 1886. In 1901 the committee's action culminated in the preparation by the county medical officer of a set of suggestions, which were ultimately approved, after amendment, by the land agents of the principal landowners in the Riding, and issued to local authorities for their guidance. In 1906 the county boroughs of Leeds, Bradford, Sheffield, and Rotherham, and the county councils of the East and West Ridings, caused a joint investigation to be made into the causes and sources of the contamination of milk, which showed that the greatest amount of contamination took place at the farm. Leaflets were thereupon prepared and distributed to householders and to persons connected with the supply and distribution of milk. No doubt the leaflets were of value in effecting improvement; and the improvement would have been greater than the facts recorded below imply had this policy been more thoroughly backed by all the sanitary authorities directly concerned. However, dirty milk is still being produced; in Dr. Kaye's report to the committee in September, 1922, it was shown that of 179 samples examined, 41 contained from 20 to 30 parts, 14 from 30 to 40 parts, and six over 40 parts per million of centrifuged fluid dirt. The present report states that there are in the West Riding administrative county 151 sanitary authorities (including two new districts for which records are not available) which have control of the cowsheds in their areas. In these 149 districts (and in that multiplicity of authorities lies the secret of the failure to get pure milk) 6507 registered cowkeepers have 9229 cowsheds, with accommodation for 51,283 cows. Officers of the sanitary authorities have to inspect all registered cowsheds in connexion with structural requirements and cleanliness of the premises, and conditions and health of the animals, especially with regard to tuberculosis of the udder. A table shows that 91, or 61 per cent., of the 149 districts made less than two inspections per annum, involving 5114 cowkeepers (78 per cent. of the total in the Riding), 7199 cowsheds, and 40,429 cows (79 per cent. of the total cows in the Riding). Thus there are to be found a large number of insanitary cowsheds, subjected to altogether inadequate inspection, and much dirty and tuberculous milk. Other tables show that rural districts are much less careful than urban districts in the matter of inspection. During the last two years the survey of three Poor-law unions has been completed, and 847 cowsheds have been inspected; an analysis is included, giving the Board of Agriculture's requirements in the matter of cubic space, ventilation, lighting, flooring, drainage, and water-supply, together with the actual findings of the county staff. A glance at this analysis shows the justification for Dr. Kaye's concluding paragraph, in which he urges the need for: (*a*) a great improvement in the sanitary construction of cowsheds—many of the buildings now in use were never intended for cowsheds, and cannot without reconstruction be made fit for their purpose; (*b*) better inspection of cowsheds to secure greater cleanliness, and careful inspection of the cows for the detection of unhealthy or definitely tuberculous animals. Dr. Kaye is to be congratulated on a valuable survey which deserves more than local consideration.

---

[1] THE LANCET, 1916, ii., 423.

TULARÆMIA AND ITS CONGENERS.

THE *Bacterium tularense* was first described by McCoy and Chapin as the cause of a severe epizootic among ground squirrels in the Tulare district in California about ten years ago. A few years later it was identified by Wherry and Lamb as a cause of human disease, the first cases to attract attention showing a severe form of conjunctivitis, from which the organism was recovered. Within the last two or three years it has been established that infection is widespread among jack-rabbits in Utah and that it is not infrequently transferred to man, causing an undulant fever lasting several weeks with considerable general depression and malaise; fatal cases are almost unknown. The bacillus is pathogenic to many species of mammals—rabbits, mice, guinea-pigs—and experimentally infection can be acquired by close contact or through the agency of a variety of biting insects—blood-sucking flies, lice, fleas, bugs, acarids—which seem to act merely as mechanical transporters and inoculators without playing any necessary part in the life-cycle of the organism. It is suggested that infection is kept up among wild rabbits by the common rabbit-louse *Hæmodipsus.*

Naturally infection in man occurs among agriculturists or market men who handle or dissect infected rabbits. But since the discovery of the bacillus it has been characteristic that many laboratory workers who have dealt with it have been infected. The recent annual report of the Medical Research Council, and a short notice by Prof. Ledingham in the last number of the *Journal of Pathology and Bacteriology* (vol. xxvi., p. 133), remind us that in their efforts to maintain the virus in the National Collection of Type Cultures at the Lister Institute, Dr. St. John Brooks, Miss Rhodes, and Dr. Schütze successively took the disease. They are now happily recovered, more or less. The organism is difficult to grow on artificial media, and its continued maintenance by this means is rather speculative. It is hence customary to carry it on by passage in animals, and it is this procedure which has habitually proved so dangerous, and which, by a brave discretion, has been given up by the Institute. How exactly infection is taken is not known. The organism is very small—plainly visible under the microscope but not much larger—and occurs in the tissues of some infected animals in such enormous numbers that emulsions of their organs may be used like cultures for diagnosis by agglutination tests. Animals are not easily infected except through abrasions of the skin, which in these human cases can presumably be excluded.

It is noteworthy that one of the other few organisms with which laboratory workers have often been infected—the *Micrococcus melitensis*—is also very small and gives rise to an illness of something the same type as tularæmia. The *Bacillus abortus* of epizootic abortion in cattle, which is indistinguishable from *M. melitensis* in culture, occurs intracellularly in the uterus in prodigious numbers, just as *B. tularense* fills the liver-cells of the mouse. Cultures of bacteria are generally harmless enough. The tubes of media, found lately in the Brixton-road, were more curious than significant, and the man who stole the blue bacillus would probably have been no nearer clinching his argument about the rights of man by a violent water-borne epidemic if it had really been, as he supposed, a culture of the cholera vibrio. But *Bacterium tularense* seems to offer possibilities, at any rate, for a novelist's drama in a sporting country house.

SPECIMENS BY POST.

THE value and variety of laboratory investigations in relation to medicine are increasing so rapidly that as an inevitable result extraordinary numbers of pathological specimens are nowadays transmitted by post. The Postmaster-General is again calling attention to regulations, framed for the protection of the postal staff and of other mails, but which are broken with considerable frequency. On page 264 we print the essential part of the official requirements, and we would emphasise here the fact that, besides subjecting public servants to annoyance and sometimes to risk, improper packing results in complete and immediate destruction of the contents together with all wrappings and every enclosure. It seems to be generally realised that letter post only is available and that the package must be clearly marked "pathological specimen," but central laboratories remark how often the receptacle containing the material itself is not properly enclosed and steadied within a strong, impervious, and preferably metal case. When the glass comes to grief it is usually through inadequate outer protection. All laboratories which deal with a large number of postal specimens send out postal containers complying with the regulations, and arrange to provide the practitioner with a returnable stock of these things. Should these not be to hand, a tin well lined with cotton-wool may be requisitioned just as readily as the unsatisfactory cardboard box, and these facts should be explained to patients who are instructed to send off their own specimens. Haphazard transmission of materials from private houses is one of the chief sources of trouble. We are glad to learn that further perfection of postal outfits is under consideration by the laboratories themselves, and a few points taken from their suggestions may help to illustrate the degree of care which this matter demands. Tins with turn-down clips or metal fastenings, liable to break off and damage the hands of sorters and postmen, or to injure other contents of the mail, will be done away with in favour of screw-on or internally secured lids. Envelopes commonly used to hold metal swabs are being made from specially untearable material and secured by metal clips so that pressure cannot possibly break the paper and allow the contents to escape. The absorbent material within the containers will be impregnated with antiseptic. Also each inner receptacle (bottle, swab, &c.) will be clearly labelled as to its pathological content, so that, should it by chance escape, its nature will still be obvious. When these further improvements have been made, the standard laboratory outfits should, of themselves, meet the most exacting requirements. Their routine employment would avoid specimens getting "lost in the post."

TESTICLE TRANSPLANTATION.

Richard Mühsam,[1] from the Rudolf Virchow Hospital in Berlin, reports his experience with transplantation of the testicle in the human subject. He has performed the operation on five individuals.

The first was a castrated and impotent man aged 25. In April, 1918, the transplantation was carried out, in November of that year libido appeared, and in March, 1919, he married. Coitus took place regularly every two to three weeks, and he felt perfectly well. His voice, which was previously high, became deep, and the prostate became normal in size. The second patient was a man aged 26 with bisexual inclinations. From the tenth to the twenty-eighth day after operation he experienced strong heterosexual desire, and two months later the first coitus took place. He married and is now father of a child. The third case was a 26-year old homosexual man. Five days following transplantation and removal of one testis he had heterosexual dreams, and in the next week took an active interest in a young woman. Circumstances did not, however, permit of greater intimacy, and the desire gradually diminished until he became once more completely homosexual. A second operation was carried out two months after the first, and shortly afterwards he had a heterosexual dream, but then returned once more to his previous condition. Six months later he developed a temporary sensitiveness towards women, followed by a complete and lasting return to homosexuality, and he became resigned to his fate. The fourth case was a homosexual individual, in whom no change took place until six months after the operation, when increasing interest in women developed and remained. He now considers himself as normal. The last case was a eunuch, dwarf and obese. One to two months after operation he experienced numerous erections, which had previously been absent, but they did not last, and he soon returned to his former state.

---

[1] Deut. med. Wochensch., Oct. 6th, 1922.

Thus, out of five cases three could be said to have been successful and two had no result. In discussing the cases Mühsam mentions the experiments by Förster and others who have removed the transplant at a later date and found that necrosis invariably occurred. While recognising the probable truth of these observations, he suggests that in his cases possibly enough of the tissue survived to produce sufficient secretion to carry out the male functions, and he supports this theory by reference to the work of Lipschütz,[2] who showed that in young guinea-pigs, if all testicular tissue is removed save 1 per cent. of the weight of the two testes, the animal develops normal male characteristics. The histological appearance of the remaining portion resembles that of a testis after ligature of the vas deferens (Steinach's operation) of a cryptorchid, or of a transplanted or X rayed testis. Mühsam discusses also the possibility that suggestion plays a part in the favourable results, but he discounts this probability, as in each of his cases extensive psychotherapy had been previously carried out without success. The rapid improvement in the second case is, indeed, remarkable and suggests a psychic factor, but in the fourth case the patient himself had given up all hope of improvement and doubted the possibility of success. Subsequent to the operation he received no further psychic treatment, but his feelings changed so markedly that he was obliged to cast off his pessimism and to express entire satisfaction with the operation. In the two unfavourable cases it must be noted that temporary phenomena occurred which the patients had never previously experienced. The homosexual patient developed a strong attachment to a woman, and Mühsam thinks it possible that had this attachment been carried to its conclusion the change might have been permanent. The eunuch experienced erections for the first time, but they did not last. The inference in these cases is that some secretion from the testis was absorbed by the patient in the early stages before necrosis set in.

Observations are also being made by Curt Pariser in Woltersdorf-Berlin[3] on the action of a new preparation of testicular tissue which he has brought out, with which he claims that effects can be obtained similar to those seen after Steinach's operation. Pariser argues that whereas after Steinach's operation there is in the early stages marked improvement in the patient's condition, this is only temporary, possibly due to congestion of the organ, and is followed by a complete cessation of hormone formation, with a sudden and permanent collapse of the patient. By substituting a preparation which can be administered internally, careful dosing may be undertaken, and overdosing, with symptoms of testicular intoxication (sometimes noted after Steinach's operation), can be avoided. The preparation is known as rejuven masculinum (rejuven femininum is still under preparation) and is taken in the form of tablets of 0·05 g., corresponding to 3·5 g. of fresh gland substance. The choice of cases is important, as in all other forms of treatment. Little or no result may be expected in patients with complete or almost complete atrophy of the testicles. In cases of early senescence the best results are to be expected, the signs of rejuvenation including the regrowth of hair of the patient's normal colour, instead of grey or white, recovery of the elasticity of the skin and other tissues, and increase in physical strength. The power of mental concentration improves, the appetite becomes strong, and the weight is increased. Arteriosclerosis is materially benefited, the blood pressure falling 20 to 30 mm. Hg. Sexual power usually returns early in the treatment for a short time, but is not permanent. Pariser, however, does not consider this as the chief aim and object of the treatment. He maintains that the chief indications for treatment are failing physical powers, arteriosclerosis in its early stages, senile cataract, and early senile dementia. A latent period of three to six weeks or longer is always present. The end of the latent period is marked by certain symptoms—namely, great general unrest, irritability, increase in anginal pains, if these were present before, strong sexual and other dreams of an exciting nature. In one case the patient did not dare to take the three tablets ordered daily because he noticed that he was troubled with dreams if he did so. When these symptoms appear, and they are to a certain extent symptoms of overdosing, the treatment is discontinued for one to three days, and then recommenced with two tablets daily, increased in six to seven days to three. It is, however, seldom that the latent period is closed entirely without sexual dreams, and in some cases libido and potency are increased to youthful strength. Pariser thinks that the sequence of events from Steinach's operation to the use of rejuven has followed that of the first transplantation of the thyroid in myxœdema to the use of thyroid extract. These reports are of especial interest as they come at a time when organotherapy is being strongly condemned in this country by some of our leading thinkers.

ANAPHYLAXIS AND IMMUNITY.

THERE is sometimes confusion over the apparent contradiction that an animal enters upon the anaphylactic state at the same period as its blood develops those properties which are indicative of the state of immunity—that is to say, that immunity and supersensitiveness can and do exist in the animal body at the same time. In a recent number of the *Annales*[1] of the Pasteur Institute, S. Metalnikov has examined this phenomenon and put forward its rational explanation. After reviewing the general nature of the anaphylactic phenomena, and their widespread incidence in nature, the author states that the essential for their production is an increased cellular sensibility, which is, as is well known, one of the most widely accepted current views upon anaphylaxis. This sensibility is essentially of the nature of a protective phenomenon, the cells which have once been damaged by a particular agent reacting, on a subsequent occasion, more energetically to the presence of this agent. To prove the presence of this increased cellular activity the author has introduced capillary tubes filled with the antigen in question both into the peritoneal cavity and beneath the skin of animals which have received sensitising doses of the same antigen some weeks previously, and are therefore sensitised from the anaphylactic point of view, and have developed immunity from the immune point of view. Removal of these tubes some 10–12 hours later shows that in the sensitised animals they have become stuffed with emigrated leucocytes whilst in the control normal animals the leucocyte immigration has been minimal. This, of course, is a result which would have been expected from the classic researches upon phagocytosis; its clinical demonstration in anaphylaxis is in the Arthus phenomenon, where a local subcutaneous injection of the specific antigen, in a sensitised animal, leads to a violent reaction and a pronounced local accumulation of motile cells.

[3] Deut. med. Wochensch., Oct. 13th, 1922.

[1] L'Anaphylaxie et l'immunité, par S. Metalnikov, Annales de l'Institut Pasteur, vol. xxxvi., No. 9, September, 1922.

On the other hand, where the animals have been desensitised and their sensibility removed by a slow introduction of the antigen into the veins in a manner which does not give rise to anaphylactic shock—where in Besredka's phase they are in the anti-anaphylactic state—the experiments with capillary tubes do not succeed, the previously anaphylactic animals behaving in the same way as the normal ones. This is a phenomenon which can be imitated in experiments on chemiotaxis with protozoa; the organisms, or the leucocytes in the human subject, have gorged themselves with the antigen in question and have lost all the special sensibility towards it when presented with it at a later date. Upon the assumption of the importance of cellular activity in these phenomena the findings of Roux and Besredka, of their inhibition by anæsthetics and narcotics, are readily explicable. Such facts as we have already touched upon have been studied chiefly in the leucocytes, which are especially readily examined, but they are representative of the body cells; and the same phenomena undoubtedly apply to most of these cells, which are altered in their potentialities for response to infections by a previous exposure to such an infection. This fact finds its proof in the demonstration of anaphylaxis in the isolated organs of sensitised animals, which was first carried out by Schultz, and at a later date by Dale in this country; a fact which can be demonstrated in organs freed of blood by perfusion.

The conclusion is that anaphylaxis and immunity are but different sides of one and the same phenomenon—a process which has for its end the protection of the subject. Where a subsequent infection is only moderate the obvious result is resistance, which depends upon "immunity"; but where the second infection is of overwhelming intensity, as in the highly artificial conditions realised in experiments on anaphylaxis, this same reaction takes place in an ultra-violent fashion and untoward results occur; this is "anaphylaxis," dependent, in strict parlance, not on supersensitiveness but upon an increased protective reaction.

THE FUNCTION OF CAROTINOIDS IN ANIMALS.

OF recent years much work has been done on the pigments, which range in colour from yellow to red, and which are contained in ethereal extracts of many plant and animal tissues. Luteins, lipochromes, lipoxanthins, chromolipoids, and carotinoids are names which have from time to time been suggested for this group of colouring matters, and some confusion has been caused by the use of different names for the same substances. The considered statement on the present position of the subject, which has recently been offered in the form of a monograph by Prof. Leroy S. Palmer,[1] will interest many workers in biological chemistry. The author prefers to call the whole class of these pigments the chromolipoids; one widely distributed member of this class is the pigment carotin (spelt *carrotene* by the English Chemical Society); very many others are closely related to carotin, and are therefore called carotinoids. The two most important classes of carotinoids are carotins, which are hydrocarbons either identical or isomeric with carotin $(C_5H_7)_8$, or $C_{40}H_{56}$, and xanthophylls, which are oxy-carotins—e.g., $C_{40}H_{56}O_2$. The first animal chromolipoid to be isolated was the pigment of the corpus luteum. In the cow this is known to be carotin, though in other animals its identity is a matter for future work to decide. The pigments of the blood plasma may be either carotin or xanthophyll, or, in man, both of these; these are not the sole pigments, however, because in man and in the horse some bilirubin may also be present. When the milk fat is pigmented this is due to the passage of the chromolipoids of the plasma into the milk, and the same is true of the pigmentation of adipose tissue, internal organs, nerve cells, and, to some extent, the skin. In diabetics, for example, it is stated that the skin may be pigmented with carotinoids; the author suggests that this is in part due to lack of the normal oxidative mechanism by which the carotinoids are destroyed in the body. The carotinoids are transported from place to place in the body with the fats, and it has more than once been suggested that these substances are identical with the fat-soluble vitamin. A critical review of the evidence on this point shows, however, that the substances cannot be identical; though in plant tissues, but not in animal tissues, there does seem to be a close correlation between the occurrence of vitamin A and carotinoids. The similarity of distribution between lipochrome pigments and the fat-soluble accessory food factor was pointed out in our own columns by O. Rosenheim and J. C. Drummond,[2] who came to the conclusion from their experiments and from a survey of other work that the association was not one of identity. It would seem, therefore, that animals possess the power of separating these substances one from another. In plants the carotinoids appear to have definite functions, especially as light filters; though there is no evidence that they originate from chlorophyll, they assist this substance in the work of carbon assimilation. In animals they appear to have no function. They are derived from the food, ultimately from plants therefore.

A PLENARY HEALTH INSURANCE CONFERENCE.

A CONFERENCE of bodies interested in the medical service of the National Health Insurance Acts met in the Council Chamber of the Guildhall, London, on Tuesday and Wednesday of this week. The conference was called by the Insurance Acts Committee of the British Medical Association, and Dr. H. B. Brackenbury, as chairman of this Committee, presided over it. Delegates from 16 groups of Approved Societies attended along with representatives of Insurance Committees and their Clerks, and from the Retail Pharmacists' Union, and the whole membership of the Insurance Acts Committee. Dr. Brackenbury, in his opening address, described the gathering as the first plenary conference of National Health Insurance. The Acts, he said, were both complicated and incomplete, but they provided the machinery for making their officers aware of imperfections. The time was premature for a comprehensive inquiry into the effect of the Acts on the health of the people; war, demobilisation, and unemployment had successively interfered with their normal working. But the doctors were no longer antagonistic, disciplinary action was having its effect upon the less zealous, and additional benefits were beginning to mature. "We who work the Acts," he said in conclusion, "are met here to pool our experience, to discuss our difficulties, and to create a better atmosphere." In this spirit of mutual forbearance and frank exchange of view the three long sittings were spent. The subjects discussed were:—

1. Title to Benefit—introduced by Sir William Glyn Jones.
2. Efficiency of Service Rendered—by Sir Thomas Neill.
3. Certification—by Dr. H. G. Dain.
4. Supply of Drugs and Appliances—by Mr. G. A. Mallinson.
5. Work of Regional Medical Officers—by Dr. E. K. Le Fleming.
6. Extension of Services—by Dr. Brackenbury.

---

[1] Carotinoids and Related Pigments: The Chromolipoids. By Leroy S. Palmer, Ph.D., Professor of Agricultural Chemistry, University of Minnesota. American Chemical Society, Monograph Series. New York: Chemical Catalog Company, Inc. 1922. Pp. 316. $4.50.

[2] THE LANCET, 1920, i., 862.

7. Sickness Benefit—by Dr. H. F. Oldham.
8. Deposit Contributors—by Dr. H. S. Beadles.

It was evident from an early stage of the proceedings that the conference did not consist of two groups—medical and lay—with well-defined and divergent views. Most of the extremer criticism of the medical service was met by speakers from the same benches. For instance, when the grievance was ventilated that the insured person who wished to see the principal was often put off with an assistant, it was pointed out from several sides that the training of assistants in insurance practice was not only natural and inevitable, but also in the best interests of the insured person. The need for increased waiting-room accommodation was admitted all round, but no one was able to put forward any specific remedy for queues of patients. Perhaps greatest unanimity was present in respect of the failings of the insured person himself—who was unrepresented as such at the conference—and the suggestion to supply a model lesson for school-leavers on the privileges and duties of health insurance was warmly welcomed. The immediate outcome of the conference was the unanimous decision to appoint a standing committee to consider the suggestions made at the conference, and other points that might arise, with a view to improving the services rendered to the insured person—the committee to report to a later conference. It was agreed that the constitution of the standing committee should be six representatives of approved societies, six of the medical profession, four of insurance committees, and two of pharmacists.

WE regret to announce the death on Jan. 28th of James Ritchie, M.D., F.R.C.P. Edin., Irvine Professor of Bacteriology in the University of Edinburgh.

THE opening ceremony in connexion with the Maudsley Hospital, Denmark Hill, was performed on Wednesday morning by the Minister of Health, Sir Arthur Griffith-Boscawen.

AT the Royal College of Physicians of London the following lectures will be delivered on Tuesdays and Thursdays, at 5 P.M. Milroy Lectures by Dr. W. G. Savage on Canned Foods in Relation to Health, Feb. 22nd, 27th, and March 1st. Goulstonian Lectures by Dr. Geoffrey Evans on the Nature of Arterio-Sclerosis, March 6th, 8th, and 13th. Lumleian Lectures by Dr. Arthur J. Hall on Encephalitis Lethargica (Epidemic Encephalitis), March 15th, 20th, and 22nd.

PASTEUR CENTENARY.—In connexion with the centenary, a lecture on Pasteur will be delivered to-day (Friday) at 4.30 P.M., in the rooms of the Royal Society, Burlington House, London, W. 1, by Dr. Pasteur Vallery-Radot, Médecin des Hôpitaux de Paris, grandson of the scientist. Sir Charles Sherrington, P.R.S., will take the chair. The lecture is the first of a series to be delivered during a tour of Great Britain ; the tour has been organised by the Alliance Française with the support of the councils and health officers of the towns to be visited.

FELLOWSHIP OF MEDICINE.—Representatives from the staffs of the hospitals interested in the establishment of a scheme of post-graduate education in London have been invited by the Fellowship of Medicine to a conference to be held at the house of the Royal Society of Medicine, 1, Wimpole-street, London, W., on Feb. 8th, at 5 P.M. The aim of the conference is to discuss how far the Fellowship of Medicine can continue to promote the cause of post-graduate instruction and hasten the time when a permanent and comprehensive organisation in London is an accomplished fact.

A course of seven practical lecture-demonstrations on Certain Diseases of Children will be held during February at the Children's Clinic, Western General Dispensary, Cosway-street, N.W. 1, on Tuesdays and Fridays, at 5 P.M. The first on Feb. 13th and the last one on March 5th will be given by Prof. Sir William Bayliss and the other five by Dr. Bernard Myers, whose concluding lecture will be devoted to the Nervous Child, as seen in General Practice. The fee for the course is one guinea and copies of the syllabus can be obtained from the Secretary to the Fellowship of Medicine, 1, Wimpole-street, W. 1.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

V.—THE TREATMENT OF SCABIES AND PEDICULOSIS.

THESE two parasitic diseases of the skin require, as a rule, only external treatment, and, if this is correctly carried out, they can usually be eradicated without much difficulty. The question often arises in private practice whether or not it is advisable to tell a patient that he or she is suffering from a parasitic infection, since most people regard all skin eruptions as loathsome, however " pretty " they may appear to the dermatological eye, and have a peculiar horror of the two diseases under consideration. Moreover, the pathetic state of mind known as parasitophobia may date from an actual infection with one of these, although more commonly it arises from a faulty interpretation by a disordered mind of a pruritus due to a non-parasitic cause. My own opinion is that, unless, perhaps, one is dealing with a highly neurotic or imaginative person, it is better to explain clearly in non-medical terms the cause of the eruption, how it was probably acquired, the risk of contagion, and the method by which one proposes to cure it. The modern patient of intelligence is not easy to bluff, and one is more likely to render him hypochondriacal by suggesting that his scabies is due to gout or indigestion, which he will probably regard as incurable, than if one tells him the truth and assures him of a complete cure within a short time.

Scabies.

The diagnosis of scabies, easy as a rule among the poorer classes, may be difficult owing to the paucity of lesions in those who take a daily bath. There may be no evidence of the disease on the hands and wrists, and in private practice the elbows, the anterior axillary folds, the abdomen, *the skin over the ischial tuberosities*, the knees, the ankles, the nipples in women, and the penis in men are the parts most likely to be affected. The finding of a typical " burrow," with or without a female acarus within it, is certain evidence of scabies ; also the diagnosis can be made with confidence from the appearance and distribution of secondary lesions.

Once the diagnosis is established it is essential to determine, preferably by inspection, whether any other members of the household are affected ; not uncommonly the disease is introduced into a family by servants or nurses, who may act as constant sources of reinfection. Obviously the treatment of all affected persons in the house must be carried out at the same time. The three-day cure with sulphur ointment, which proved so successful in the army during the war, is usually effectual if conscientiously carried out, and Dr. A. Whitfield recommends the addition of cyllin : ℞. Cyllin, m. 20, ung sulphuris, B.P. (half strength), ad ℥i ; balsam of Peru (m. 40, ad ℥i) may be substituted for the cyllin. The Danish method of treatment is, however, preferable, since for it only 24 hours are necessary, and the percentage of cures is equally high or even higher. The ointment used was devised by Marcussen, and its preparation is somewhat complicated. For private practice it is simpler to use the commercial form, which has been put on the market under the name of " Kathiolan."

The technique of the treatment is as follows : The patient takes an ordinary hot bath, lasting from 10 to 20 minutes, in which he lathers himself well with soap ; after drying, he rubs the ointment thoroughly into the skin of the entire body from the neck downwards. He then dons pyjamas or a suit of underlinen, his hands and feet are kept covered in stockings so that the ointment is not rubbed off, and he retires to bed. Twenty-four hours later another bath is taken, fresh or disinfected clothing is put on, and the cure is complete. Bed linen and underclothing should, of course, be disinfected in the usual way. For patients who cannot afford to spend 24 hours in bed, I usually advise application of the ointment for two or three nights in succession. A certain amount of irritation, and in seborrhœic subjects a mild sulphur dermatitis may follow this treatment, but these rapidly subside when a dusting powder or soothing cream is used for a few days; in my experience sulphur dermatitis is less frequent and less severe than with the three-day ointment cure.

Whichever method is employed the patient must be emphatically warned against using the sulphur preparation for longer than the prescribed time, and he should be told that, if irritation of the skin is still felt after the treatment has been properly carried out, it will almost certainly be due to the sulphur and not to the acarus. In spite of warning many patients persist in continuing their sulphur inunctions until a violent dermatitis results. In my experience non-success in the treatment of scabies by either of these two methods depends usually on: (1) faulty technique, such as applying the ointment only to certain parts where the eruption is most evident; (2) reinfection either from imperfectly disinfected clothing, or from other persons in the household who have been left untreated.

Pediculosis.

Pediculosis Capitis.—Diagnosis of this disease is seldom difficult, as the ova are easily found if diligently sought for. In cases without severe secondary infection the parasites and most of the ova may be destroyed by the thorough application of petroleum; this should be well rubbed in until the hair is saturated and the head should then be enveloped in a towel for a night. In the morning the scalp should be shampooed, and the ova may be removed with a fine comb, their removal being facilitated by the application of dilute acetic acid (5 per cent.). As an alternative to the use of petroleum the following method, advocated by Dr. Whitfield, is simple and absolutely reliable: The hair is saturated with a hot solution of carbolic acid (1 in 40), the patient, if a girl, lying on her back with her head projecting over a basin placed on a chair. The hair is placed in the basin into which the carbolic solution is poured over the head from before backwards. The excess of fluid is squeezed out of the hair, which is then enveloped in a towel and left from one to two hours, before being dried completely. In cases in which a severe impetiginous or eczematous dermatitis is already present at the first consultation, it is better to remove the crusts and subdue the inflammation by means of hot fomentations of boric acid lotion or a $\frac{1}{2}$–1 per cent. solution of lysol, applied at night, and a 1 per cent. mercurial ointment under a linen cap during the daytime. After the destruction of the parasites and ova the secondary impetiginous infection usually clears up rapidly; if necessary, the scalp may be shampooed every three or four days with a 2 per cent. solution of lysol, and a weak mercurial ointment (ammoniated mercury or the yellow oxide 1–2 per cent. in vaseline) applied. It is, of course, advisable to sterilise hats and caps by stoving, and brushes in a hot lysol solution.

Pediculosis Corporis.—Our knowledge of the habits and activities of the body-louse was materially advanced during the war. Previously, although the fact had been noted, it was not generally recognised that this parasite may lay its eggs on the hair of the pubis and other parts of the trunk as well as on the clothing; sterilisation of the latter, therefore, is not necessarily sufficient, since auto-reinfection may occur. Individual susceptibility to louse infection varied greatly in different subjects.

The lesions characteristic of pediculosis corporis, apart from pigmentation, are linear scratch marks (contrasting with the pin-point follicular marks of scabies), ecthymatous sores ("linear impetigo"), and abscesses formed from infected bites, which differ in appearance and in the colour and consistence of their purulent contents from ordinary boils. The distribution of the lesions is almost pathognomonic, the parts affected being the shoulders and *posterior* axillary folds, the sacral region and *upper* parts of the buttocks, and the outer surfaces of the thighs and legs. In scabies, it should be noted, the back is usually relatively free from lesions, and the *anterior* axillary folds and the *lower* parts of the buttocks are involved, but the two diseases may, of course, be coexistent. Occasionally—probably in persons who have never before been infected—the body-louse produces an acute eruption of small, red, intensely itchy papules, which may be distributed over most of the trunk and upper segments of the limbs, and a febrile reaction may occur, presumably in response to the toxin injected by the parasite.

The treatment of pediculosis corporis is simple, but, of course, in those who live in infested dwellings or doss-houses reinfection is sure to occur. A hot bath, followed by a few inunctions of an ointment containing ammoniated mercury (2 per cent.), stavesacre (ung. staphisagriæ, B.P.) or sulphur (2–3 per cent.), together with thorough disinfection of the clothes and bed-linen, is all that is necessary. The secondarily infected lesions should be treated by frequent bathing, evacuation of abscesses, removal of crusts, and the subsequent application of a weak mercurial ointment. It cannot be said that any very satisfactory method of preventing pediculosis was discovered during the war. Divisional baths and steam sterilisers were available to some extent. In civilian life clothing and bed-linen should be boiled when practicable, and the remainder heated in an oven to a temperature of 160°–175° F.

Pediculosis Pubis.—Infection with this variety of louse is very common. Those who become infected often diagnose their complaint correctly, and fly to the traditional blue ointment—sometimes thereby provoking an acute mercurial dermatitis. It must be remembered that, although the pubis is the region usually first involved, the parasites soon invade the axillæ, and in hirsute persons the lanugo hair of the whole trunk and limbs may harbour them. More rarely the eyelashes and beard become infected. Apart from the irritation it occasions, the pediculus pubis may in certain persons produce characteristic oval bluish spots, which are macules (maculæ cæruleæ) and do not fade on pressure. At one time they were thought to be symptomatic of typhoid or typhus fever. They are caused, as Duguet's experiments with crushed crab-lice showed, by the pigment introduced by the parasite when feeding, but it would seem that only certain affected persons develop them. Although the crab-louse—like the acarus—is often acquired through indiscriminate sexual intercourse, it may also be transmitted by w.c. seats and articles of clothing.

Blue ointment is not to be recommended owing to the risk of mercurial dermatitis. The method I usually advise is to apply pads of lint, soaked in a 1 in 40 solution of carbolic acid and covered with oil silk and bandage, to the affected regions for an hour or so. On removal of the pads the parasites are found dead and adhering to the lint. Subsequently it is wise to employ a weak mercurial ointment for a few days, lest any ova should have escaped destruction by the carbolic acid. Petroleum or xylol are equally efficacious and kill the parasites instantly, but I have never yet failed to cure a case rapidly by means of a carbolic solution and a weak mercurial ointment. The beard may be treated in the same way, but when the eyelids are affected it is best to pick off the parasites and as many ova as possible with forceps, and to apply the oculentum flavum B.P.C. continuously until a cure is obtained.

Special Articles.

VENEREAL DISEASES IN NEW ZEALAND.

THE Committee of the New Zealand Board of Health, appointed in July, 1922, by the Minister of Health to inquire into the subject of venereal diseases in the Dominion, have now issued their report. They remark that the carrying out of their task had brought them into contact with some uninviting aspects of the social life of New Zealand, and that some of the facts disclosed should give serious concern to all who had the welfare of the country at heart. The information is included that, during the war, of 135,282 New Zealanders examined after the introduction of the Military Service Act, who were mostly young men, only 57,382, or, roughly 42·5 per cent., could be accepted as fit for training. This serves to remind Englishmen who found food for disquieting thought in the difference between the average physique of Colonials and of Home troops, that the propagation of the unfit by the unfit is a world-wide problem. The Committee find it impossible to say what proportion of defectives are the direct product of venereal disease, but " there is clear evidence that a tendency to lead dissolute lives is especially noticeable in the females belonging to this unfortunate class. . . . Obviously some method of dealing with mental defectives—by segregation or otherwise—must be found as part of the problem of dealing with venereal disease."

Conclusions.

Some of the conclusions drawn by the Committee are as follows :—

There is very general ignorance among the public on the subject of venereal disease, which has stood in the way of its being effectually grappled with. Syphilis not only causes direct loss of life, but many deaths ascribed to other causes in the Registrar-General's returns are due to its after-effects, which are responsible for many still-births and abortions, are seen in surviving children, and may persist until the third generation. Gonorrhœa, popularly supposed to be a comparatively mild complaint, is regarded by medical men as being no less serious than syphilis ; it is difficult to cure, especially in women, unless treated at the outset, and is a great cause of sterility in both sexes.

Owing to the absence of accurate statistics it is impossible to compare the incidence of venereal diseases in New Zealand with that in other countries, or to observe its increase or decrease. One person in every 428 of the population of the Dominion—3031 in all—is the figure given for persons being treated by registered medical practitioners for venereal disease in some form, or for its after-effects. At the clinics since their establishment 3634 patients have been treated (3038 males, 596 females). Dr. J. F. S. Hay, Inspector-General of Mental Hospitals in New Zealand, computes the number of persons now in the Dominion who have or have had syphilis to be 33,000, or 1 in every 38 of the population. The Committee state, however, that in their opinion no exact estimate of the prevalence of venereal diseases can be obtained until some accurate system of obtaining statistics has been adopted ; but they feel assured that venereal disease is sufficiently prevalent to call for energetic action. Evidence was given which showed that children with mental and physical defects due to venereal disease might become a charge on the State, and that a proportion of them on being released became the parents of defective children, who have also to be supported at the public expense. Such defectives have little sexual control, and are usually very prolific.

According to the Commissioner of Police there are only 104 professional prostitutes in New Zealand, but there is a great deal of " amateur " prostitution, which is chiefly responsible for the spread of venereal diseases. The evidence points to a good deal of laxity of conduct among young people of all social conditions, especially in large towns ; this is generally attributed by witnesses to the weakening of home influence and the restlessness of the age. Apart from the disease among those who indulge in promiscuous intercourse, innocent wives are in many cases infected by their husbands, and in a few cases innocent husbands are infected by their wives. Children suffer innocently from venereal diseases, not only by inheritance from infected parents, but by accidental contact with germs on towels, &c., which have been used by a patient. Cases also come before the courts where disease has been directly conveyed in crimes of violence by sexual perverts.

The free clinics in the chief centres, conducted by experts, are doing good work, but their influence is greatly hampered by the fact that a proportion of the male patients and the majority of the female patients leave off treatment before they are cured. There is no power, as the law stands, to compel them to continue treatment, and in many cases they resume promiscuous intercourse and spread the disease. Some persons suffering from disease do not seek medical treatment, and communicate it to others ; these persons also cannot at present be restrained from such conduct or compelled to receive medical treatment.

Recommendations.

The Committee emphasise in the strongest terms the duty of moral self-control, and urge the cultivation of a healthier state of public opinion. The stigma at present attached to sufferers from venereal disease should be transferred to those who indulge in promiscuous sexual intercourse. There is too little realisation of parental responsibility in the matter of sex instruction of children, and too little parental control generally in New Zealand. The Committee recommend the training of teachers and provision for appropriate instruction in schools.

Classification and, where necessary, segregation of mentally defective adolescents is recommended, together with the following measures for preventing and combating the disease : Clinics to be open continuously ; every effort to secure privacy at clinics ; a specially trained nurse to be in attendance at women's clinics, and, where possible, women doctors to be secured ; provision for prompt preventive treatment ; " lady patrols " appointed in other centres to perform the work now carried on by them in Christchurch. In the light of the good work, especially along educational lines, now being done by the Social Hygiene Society in Christchurch, voluntary work of the same kind elsewhere would be very helpful.

The Committee are entirely opposed to the continental system of licensed brothels, or a revival of the C.D. Acts in any shape or form. They recommend legislation providing for what is known as conditional notification of venereal disease, by which it will be the duty of a doctor to notify to the Health Department, by number or symbol only, each case of venereal disease he treats ; if a patient refuses to continue treatment until cured, and will not consult some other doctor or attend a clinic, it will then be the duty of the doctor to notify the case to the department by name. If the patient continues recalcitrant and refuses to allow himself to be examined by the medical practitioner appointed by the Director-General of Health, then the latter should be empowered to apply to a magistrate for the arrest of such person and his detention in a public hospital or other place of treatment until he is non-infective.

The Committee also recommend further provision to deal with cases where persons suffering from venereal diseases are not under medical treatment and are likely to infect others. If the Director-General has reason to believe that any person is so suffering he may call on that person to produce a medical certificate, which may be procured free of charge at any hospital or venereal disease clinic. If the person refuses to produce such a certificate he or she may be taken before a magistrate, who may order a medical examination. Penalties, including detention in a prison hospital, should be provided for recalcitrant cases. The proceedings in all such cases should be held in private unless the defendant desires a public hearing.

The Committee recommend that before a licence to marry is issued the intending parties must sign a paper answering certain questions as to freedom from communicable disease and from mental disease, and must make a sworn statement that the answers to such questions are true. They recommend the adoption of a provision in the Queensland Act making venereal disease a ground for annulling a marriage contracted whilst one party is suffering from a venereal disease in an infectious stage, provided the other party was not informed of the fact prior to marriage. It should be the duty of a medical practitioner attending a case of venereal disease, if he believes that his patient intends to marry, to warn him or her against doing so, and if he or she persists, to notify the case by name to the Director-General of Health, whose duty it should be to inform the other party, or the parents or guardian of such party. Such communication made by the doctor or by the Director-General of Health should be absolutely privileged.

The Committee recommend that the law prohibiting treatment of patients for venereal disease by unqualified practitioners should be strengthened, and suggest that the Pharmaceutical Society might assist in preventing such practices.

Moral and Social Aspects.

The Committee believe that conditional notification and compulsory treatment along the lines suggested will not be prejudicial to women in any way, but that women will reap the greatest benefit from such measures. The only persons in the community who will be penalised by the proposed legislation will be those who, having contracted venereal disease, are so reckless and unprincipled that they will take no pains to avoid communicating it to others. The Committee, it is evident, regard the legislative and medical measures which they propose as of great importance, but they earnestly emphasise the moral and social aspects of the question, especially the duty of parents towards their own children, and the duty cast upon leaders of public opinion and upon the community at large to do what is possible to bring about better conditions of living, particularly for girls in the towns, to encourage all forms of healthy sport and amusement, and to cultivate a higher moral standard. "Whatever sanitary laws may be passed, and whatever success may be attained in dealing with bodily disease, there can be no true health if the soul of the nation remains corrupt."

TUBERCULOSIS.

Some Remarkable Results of Sanatorium Treatment.

THERE is a deplorable tendency in many quarters to judge sanatorium treatment by its travesties; to blame it when patients, admitted to a sanatorium in an advanced stage and kept there two or three months before being cast adrift, ultimately die of tuberculosis. Sanatorium treatment can, of course, be caricatured into ill-repute, and it is well to give prominence to the results which can be obtained when this treatment is given a fair trial. What a sanatorium can do for its patients is shown by a recent paper by Dr. H. J. Howk, Dr. L. I. Dublin, and Dr. I. A. Knudsen.[1] Their report deals with the sanatorium of the Metropolitan Life Insurance Company at Mt. McGregor. This sanatorium was opened in 1913 for tuberculous employees of the company, whose staff numbers approximately 18,000. The company's sanatorium has 214 beds, and by Dec. 31st, 1920, 953 patients had been discharged. All but 57 were subsequently traced, from one to seven years after discharge. Of these 896 patients, 719, or 80 per cent., were at work; 90, or 10 per cent., were unfit for work; and 87, or 10 per cent., were dead. Of the 585 incipient cases, 545 were traced, and 491, or 90 per cent., were at work. Only 36, or 7 per cent., were unfit for work, and only 18, or 3 per cent., were dead. Of the 317 moderately advanced cases, 221, or 70 per cent., were at work, and of the advanced cases 20 per cent. were at work.

These figures compare so favourably with those of many other sanatoriums that it is well worth investigating the conditions under which the patients at Mt. McGregor were treated. The policy of the company is to rehabilitate the tuberculous employee as completely as possible, and he is advised to remain under treatment until his condition warrants his return to work. The seriously advanced or progressive case is welcome to remain in the sanatorium. The average duration of treatment for incipient cases was 7 months and 1 day, for moderately advanced cases 12 months and 18 days, and for far advanced cases 14 months and 10 days. The average duration of treatment for all the patients was 9 months and 29 days. In the public sanatoriums of the United Kingdom the average duration of treatment in a sanatorium is approximately three months. The difference between three months and ten months is, indeed, enormous. Another important factor is the extent to which the disease has progressed before sanatorium treatment is commenced. Eight years ago the Metropolitan Life Insurance Company instituted a system of annual examination of all its employees. When the sanatorium was first opened the proportion of advanced cases was comparatively high, but their numbers were steadily reduced by the detection of early cases at the annual examination, and by 1920 the proportion of incipient cases admitted to the sanatorium was as high as 70 per cent. Lastly, the company found work for its tuberculous employees within a week of discharge. Usually they went back to their former work, the only change being the receipt of supplementary diets on loss of weight and more frequent medical examinations.

Conjugal Tuberculosis.

A laborious and systematic investigation of the risks involved by marriage of a healthy person to a consumptive has recently been published by Dr. A. de Besche and Dr. J. O. Jörgensen.[2] They searched the notifications of pulmonary tuberculosis to the Health Department in Christiania, and found records of 742 wedlocks in which one of the partners suffered from pulmonary tuberculosis. In the case of 39 of these wedlocks both partners had been notified. In six cases both partners had been notified before marriage. With regard to the remaining 33, it was necessary to ascertain whether there had been signs of tuberculosis before wedlock or not. In 32 of these 33 cases information was obtained as to the conditions under which the patients had lived before marriage. Sixteen of them were found to have grown up in tuberculous surroundings constantly exposed to infection, and of these 16, six had also shown signs of tuberculosis at an early age. The other 16 had, indeed, grown up in healthy homes and had not been exposed to any known source of infection, but five of them had either had enlarged glands as children or had suffered from apical catarrh or pleurisy before wedlock. Thus there remained only 11 cases in which the outbreak of tuberculosis in one partner might possibly be traced to infection by the other partner. Now 11 cases out of 742 is only 1·48 per cent. The authors conclude that there is some risk of infection to a healthy person who marries a patient with open pulmonary tuberculosis. It would, however, be well to point out that little difficulty would be experienced in producing in a town like Christiania many more than 11 adult *unmarried* persons who had recently developed pulmonary tuberculosis, who had not grown up in tuberculous surroundings, and had not had enlarged glands or other signs of tuberculous infection in childhood. And when these hypothetical cases were compared with the 11 under consideration, the question might well be asked: Why should these 11 cases be regarded as evidence of conjugal infection?

By-Products of Artificial Pneumothorax.

There is probably no exception to the rule that every important advance in science brings certain gains which may seem remote from the immediate products. This point was emphasised during a discussion on artificial pneumothorax at a meeting held on Jan. 8th of the Society of Superintendents of Tuberculosis Institutions. The papers read by Dr. L. S. T. Burrell and Dr. Eleanor Soltau showed that this treatment, dramatically effective as it certainly is, must not be regarded as a measure rendering skilled, careful, and prolonged supervision superfluous. At the discussion which followed it was pointed out that the remote effects, or by-products, of artificial pneumothorax might ultimately prove even more important than the immediate therapeutic results. In the first place, it has led up to the scientific evolution of thoracoplasty—an operation which gives promise of restoring thousands of poitrinaires to comparative health. Another by-product is the influence artificial pneumothorax has had on our conception of the needs of the tuberculous lung—its need for rest and immobilisation rather than for the focal reaction of the tuberculin enthusiast and the auto-inoculation of the advocates of therapeutic exercise. A third by-product of artificial pneumothorax is the fillip it has given to institutional treatment instead of so-called domiciliary treatment. Perhaps this is the greatest achievement of all, for while it has long been recognised that the domiciliary treatment of insanity, fractures, appendicitis, and many other conditions is very unsatisfactory, it has till recently been commonly assumed that it is possible to treat satisfactorily a case of pulmonary tuberculosis at home.

ROUMANIA.

(FROM OUR OWN CORRESPONDENT.)

Importation of Foreign Drugs into Roumania.

A RECENT order issued by the Ministry of Public Welfare makes illegal the importation and sale of foreign drugs in Roumania except under the following conditions: The manufacturers or their representatives must apply in writing for a licence, and must indicate the medicinal value of their drugs, stating the composition of the latter both as regards quality and quantity. Chemical analysis of the drug must be performed by a competent analyst, whose certificate must be attached to the letter of application, together with an official certificate to show that the sale of the drug is permitted in the country of its origin. Every package must be labelled in Roumanian with the name and formula of the preparation, and each application must be accompanied by ten samples of the drug.

Distribution of Artificial Limbs to Ex-Service Men.

The Minister of War and the Supreme Board of Public Hygiene, after long deliberation, have issued a proclamation to the war cripples of Roumania (irrespective of nationality or of the side on which they fought) informing them that all those possessing worn-out or otherwise useless artificial limbs should present themselves at the nearest military hospital, where measurements will be taken and a suitable limb supplied. Free railway transport and free board in hospital will be provided where necessary.

Higher Prices of Drugs.

The National Federation of Apothecaries has prepared a new tariff for the sale of drugs, which, having been approved by the Board of Public Health, will come into force on Feb. 1st. Almost every drug will then become dearer, although the present prices are already so high that only the richest class can afford to pay them. For instance, a quantity about equal to 1 oz. of zinc and boric acid ointment costs nearly 40 lei—the price of 3 kg. (6 lb.) of meat. The price of the more commonly used drugs—boric acid, bismuth codeine, cocaine, pantopon (omnopon), iodine—has now been raised by from 10 to 50 per cent. The price of bandages has risen 25 per cent., and that of medicine bottles 100 per cent., although the latter had previously risen 350 per cent. since May, 1922. Some drugs—e.g., aspirin and chloroform—have become cheaper. Apothecaries' charges have not been raised. The constant rise of the price of drugs is explained by the fact that German and other foreign chemical and pharmaceutical factories reckon their prices in stable currencies—i.e., in Swiss francs, pounds sterling, and dollars.

Mutual Non-Recognition of Hungarian and Roumanian Medical Degrees.

Considerable difficulty has arisen owing to non-recognition by the Roumanian and Hungarian Governments of medical diplomas issued in each other's territories. This state of affairs arose from the fact that in Hungary diplomas of Roumanian universities were not, even before the war, regarded as equivalent to Hungarian diplomas; Roumanian universities admitted students matriculating after seven years' gymnasium or lyceum study, while in Hungary eight years of such study were necessary before matriculation. Although the Roumanian medical course lasts five years, the Hungarian Government would not recognise its validity; the Roumanian "reprisal," instituted early in 1922, withdrawing recognition of Hungarian diplomas in Roumania, has seriously affected hundreds of students residing in the newly-acquired parts of Roumania. The latter, of course, speak Hungarian; in the University of Cluj—the only university in Transylvania where Hungarian was formerly used—the Roumanian language has been adopted, and the more advanced medical students, who could not learn Roumanian whilst carrying on their medical studies, naturally went to the University of Budapest to finish their education and obtain their medical diplomas. These students had then to return to their native places, as Hungary, having lost two-thirds of her territory, cannot support all her own medical men; and on coming home they found themselves prohibited from practising, although their own language is still spoken in Transylvania, where even the Hungarian laws are still in force. As the non-recognition of Roumanian diplomas in Hungary was estabished before the war, it does not affect doctors with Roumanian diplomas, who have never settled in Hungary. Unless the Roumanian Minister of Public Instruction withdraws this rigorous order there is nothing left but emigration for these unfortunate Transylvanian medical men.

A Mouse in a Beer-bottle.

Some months ago two merchants, dining in a restaurant at Cluj, found a dead mouse in a glass of the beer which had been served to them. They were both ill for several days afterwards, and claimed from the brewers of the beer a sum of 100,000 lei, on the ground not only that they had been incapacitated by illness, but that they had had to forgo a business transaction which would have brought them at least that amount of profit. The brewers refused to pay any compensation, on the ground that the most scrupulous care in bottling could not prevent such an accident. Thereupon the merchants sued them for damages; medical evidence was given of the gastric disorder resulting from the incident, and the court awarded 25,000 lei to each complainant, also imposing upon the brewers a fine of 5000 lei for neglect of regulations under the Food Act, together with payment of costs.

Public Health Services.

HEALTH OF MANCHESTER IN 1921.

The retirement of Dr. James Niven was one of the public health events of 1921. His annual reports have for long been regarded as classics. The Manchester health authority, on his advice, have always taken a wide view of their responsibilities, and have been willing to undertake research work of a nature likely to benefit the community as a whole. We are glad to learn that this authority is preparing to publish in book form a review by Dr. Niven of public health work in Manchester and elsewhere during his long term of office. The report[1] for 1921 shows the great advance which has been made in the last 30 years, and at the same time indicates the large amount of work required before Manchester can be regarded as anything like a model city from the health point of view. Dr. Niven says he is little likely to exercise any influence on future policy. We beg leave to differ. His opinions are on record, and his work will survive his official retirement.

Dr. Niven directs notice to the bad policy of tipping organic refuse within the city area. He also draws attention to the serious poverty existing in 1921, and to the slight increase in the death-rate from tuberculosis which is associated with it. He thinks that venereal disease is gradually diminishing, but is not satisfied that adequate measures for prevention are being adopted. In citing the immense amount of work now done in connexion with maternity and child welfare, he expresses his conviction that the great advance achieved has been largely due to the long-continued education of mothers by the health visitors, the maternity and child welfare centres, the schools for mothers, and the school medical officer with his staff. "In this rests the hope that it will continue." State-aided housing schemes had not made much headway at the end of 1921. Formerly the population was being pushed outwards to its great benefit by demolition at the centre and building at the outskirts. This relief to central overcrowding is no longer possible, and the housing conditions of the very poor continue to become more pressing. In spite of these adverse conditions the death-rate for 1921 is the lowest on record, and infant mortality maintains the position which it has gained "but which cannot be regarded as a goal."

Vital Statistics.

Some of the principal statistics for the year were as follows: Estimated population, 744,000. Birth-rate, 23·7. Death-rates per 1000 living: All causes, 13·6; tuberculosis, 1·6; cancer, 1·3; respiratory diseases, including influenza, 3·1. Deaths per 1000 births: Infant mortality, 97; diarrhœa, &c., under 2 years, 21; maternal mortality from childbirth, 3·24. Interesting tables are given reviewing the death-rates from specified causes over a long series of years. There is a striking reduction in the fatality of enteric, typhus, and continued fevers, scarlet fever and small-pox, and, in a lesser degree, of diarrhœa, measles, and whooping-cough. Diphtheria presents no such continuous improvement. Since 1871-75 the general death-rate, infant mortality, and deaths from violence have been halved. Since 1881–85 the death-rates from tuberculosis and diseases of the respiratory and digestive system have been, approximately, halved, but there is no such improvement in urinary disease or diseases of the generative system, or in recent years from puerperal fever and other accidents of childbirth. The death-rate from cancer has more than doubled. Recent improvements in cerebral hæmorrhage, nephritis and Bright's disease, pneumonia, digestive diseases, and "overlying" are attributed in part to the diminished consumption of alcohol, and Dr. Niven thinks "it would probably do much good if the duties on alcoholic liquors were still further increased."

Tuberculosis Mortality.

The war temporarily increased the tuberculosis mortality by the stress on unfit persons joining the army, and by the inducement to tuberculous persons to work in civil occupations. The rapid decline in the tuberculosis mortality since the war has now been interrupted by poverty, diminished nutrition, and overcrowding. Dr. Niven mentions that in the autumn influenza at times simulated scarlet fever, and he also hints at some new factor at work in promoting the autumnal prevalence of scarlet fever, erysipelas, and puerperal fever. About one-quarter of the cases of enteric fever were traced to direct infection, about one-quarter to the consumption of contaminated mussels, and in the remainder the source of infection was untraced. Eleven of the 19 new cases of encephalitis lethargica began in the first quarter of the year. The end-result of 52 verified cases reported during 1920 and 1921 is given: 27 proved fatal; 12 recovered completely; 3 were very ill four months after onset; and of the remaining 10 who had been ill for more than nine months, and showed no prospect of improvement, 3 presented the syndrome of paralysis agitans; 3 showed extreme mental depression and asthenia; 3 had paresis of one or more limbs; and in 1 strabismus persisted, and there was a mental and moral change.

Venereal Disease.

The returns of the V.D. clinics show that one-third of the new syphilis patients and one-half of the new gonorrhœa patients failed to complete a course of treatment, and that only 16 pregnant syphilitic patients received treatment. There were 7068 persons (who had been recently exposed to infection) treated at the early treatment centres, and so far there is no proof that the treatment given has ever failed to protect. The cost of this early protective treatment works out at about 1*s.* 7½*d.* per attendance, and the cost of actual treatment at the clinics at about 4*s.* 10*d.* per attendance. At the end of 1921, 38 Manchester medical practitioners were qualified to receive salvarsan substitutes free of cost.

The Schick test has been carried out at Monsall Hospital in 1200 cases. Some of the conclusions arrived at are: (*a*) susceptibility to diphtheria is greatest from the second to the fifth year of life; (*b*) scarlet fever cases have a slightly increased susceptibility; and (*c*) natural immunity is transmitted from mother to offspring. By the end of 1922 it is hoped that all the Schick-positive members of the nursing staff will have been immunised.

Milk-supply.—Maternity and Child Welfare.

Lieut.-Col. J. W. Brittlebank presents a somewhat gloomy report on the milk-supply, showing that the problem of reducing the incidence of tuberculosis in cattle is no nearer solution than it was 20 years ago. The results of sampling country milk were as follows: 16 per cent. of the Cheshire milk was tuberculous, 4 per cent. of the Derbyshire, and 10·5 per cent. of the Lancashire, while no tuberculous samples were obtained from Staffordshire, Yorkshire, and Westmorland. Of 37 cases of tuberculous milk, tuberculous udders were found on the farm in 26 cases, and in the remaining 11 cases cows were sold in the interval between the taking of the sample and the receipt of the verdict on it.

Turning to maternity and child welfare work, we find that midwives attended 68 per cent. of the births, and sent for medical aid in 4033 out of 11,905 cases. The local authority paid the fee of the medical practitioner in 740 instances, and endeavoured to recover the cost in 348 of these. The proportion of still-births to live-births was 3·4 per cent. The Manchester Corporation obtained powers in their Act of 1921 for the registration of maternity homes, which ought to prove extremely useful. By-laws under the new section were approved in March, 1922.

---

[1] This report was not received within a twelvemonth of the conclusion of the period concerned, but in view of the special circumstances we make an exception in noticing it in 1923.

Ophthalmia in Newly-born Infants.

A table is given showing the notifications of ophthalmia occurring in the newly-born, and the percentage with corneal complications for the years 1911 to 1921, and that 1921 gives the most favourable percentage—viz., 2·28. The number of cases with corneal involvement was 21. All were treated at the Royal Eye Hospital, and the total damage roll was the loss of one eye in two cases.

The campaign against flies proved a failure, owing to the fact that the manure, although promptly removed from the stables, was stored on allotments, at tips, railway sidings, and iron foundries. In the last-named case the manure is used in the making of cores for hollow castings.

Chinese Eggs.

An investigation has been undertaken, at the instance of the Ministry of Health, as to eggs imported from China. By one method the eggs are dried without preservative, and with care and a quick sale this method is satisfactory. The confectioner may use the dried egg himself. In some cases, however, merchants add water and boric acid at the rate of 2 lb. to 100 lb. of the mixture, and supply the liquid mixture to the confectioner. It is hard to appreciate the need for this middle process. Another method is to dry only the whites in China, and to cask the yolks, adding 2 per cent. of boric acid. On arrival in this country water is added to the dried whites, and they are then mixed with the yolks, more boric acid being added. Various improvements in the methods of handling the eggs are recommended.

Clean Feeding.

An inquiry has been carried out with regard to the methods used for cleansing drinking and eating utensils at public-houses and eating places, and shows that in many instances the methods are anything but satisfactory. As a result of this inquiry a workable appliance for sterilising utensils has been designed by Messrs. Richmond & Co., Warrington, and is on view at the Manchester Corporation Gas Show Rooms, Deansgate.

Manchester does not apparently take smoke abatement seriously. On page 198 we are told that 372 half-hour observations were taken during the year, while the table on page 204 gives the number of observations as only 250.

Correspondence.

"Audi alteram partem."

POST-OPERATIVE "MANIA."

To the Editor of THE LANCET.

SIR,—I have read the account of the above condition by Dr. W. J. Tyson in your last issue and hope I may be permitted to supplement it.

In the first place the title is an unhappy one, for unless the term "mania" be used in a sloppy or semipopular way, it does not correctly describe post-operative insanity, which is a delirious or confusional insanity, as different from mania as an abscess is from a cancer. Of course some people still talk of religious and suicidal "mania" when they mean melancholia, but in the interest of scientific medicine the term mania should be restricted to the elated phase of manic-depressive insanity. In it the patient is, except in the most acute conditions, lucid, not confused, and not usually hallucinated. Further, the causes assigned for this form of insanity, though many and various, are among the most definite, in actual cases, in the whole domain of mental disease. Hereditary predisposition need not be present as in most other forms of insanity, for it is par excellence an acquired insanity. No brain exists but which may succumb to the effects of toxæmia, of exhaustion, or of drugs, provided the action of these be sufficiently intense or prolonged.

The only symptoms mentioned in the case described are, first that the patient's mind began to wander, and then that she quickly became maniacal. "Wandering" is characteristic of delirious, of confusional, insanity and not of mania, so it is presumed by maniacal is meant excitement, which also frequently occurs in delirious or confusional insanity. The characteristics of this form of insanity may be summed up as follows: Definite cause; sudden onset; mental confusion; multiple and vivid hallucinations; variable emotional condition, usually anxiety; excitement or stupor; acute physical illness or prostration; short course; good recovery or death; loss of memory of incidents during illness.

Lastly, though the description is not brought up to date, a full account of this form of insanity and a bibliography will be found in "Cerebral and Mental Symptoms in Relation to Somatic Disease, Anæsthetics and Toxic Agents, Traumata and Surgical Procedures," by J. C. Simpson, M.D. (London: J. Bale, Sons and Danielsson, 1898).—I am, Sir, yours faithfully,

GEORGE M. ROBERTSON.

HOSPITAL POLICY.

HOSPITAL SAVINGS ASSOCIATION.

To the Editor of THE LANCET.

SIR,—As representing a London hospital at which, after an exhaustive consideration of the scheme put forward by the above association, complete agreement has throughout been maintained between the lay and medical representatives, we feel it our duty to enumerate the following points in connexion with this scheme in the hope that the question may be properly ventilated and more forcibly brought to the attention of those who are most affected by it—the medical profession in London—as well as those otherwise interested in hospitals.

Briefly, the following are, in our opinion, substantial grounds of objection to the scheme, which, it is considered, undermines, whether it succeeds or whether it fails, the very voluntary system which it purports to seek to save:—

(*a*) If the scheme succeeds:—

1. Through the agency of a body chiefly representative of a section of the patients, it involves serious interference with the present independent management of hospitals.
2. It definitely imports, despite all statements to the contrary, an element of insurance risk.
3. The proposed interference with the present almoning arrangements must be to the disadvantage not only of those members of the profession who are connected with hospitals, but also of the general practitioner.
4. The issue is acutely forced as to the payment of the honorary medical staffs and management of hospitals.

We would here emphasise the point that the question of staff funds in the provinces is and must remain an essentially different problem from that of establishing staff funds in London.

5. By its nature, the scheme definitely controverts the existing principles of the voluntary system.

(*b*) If the scheme is put into operation and fails:—

The odium of failure will not fall on the Association, but will probably be borne by and react on the hospitals themselves, thus providing data for those in favour of State or municipal control.

We cannot too strongly condemn representations such as that this scheme involves questions of finance only, or that so far it has received the substantial consideration and unqualified approval of the hospitals of London.

We are, Sir, yours faithfully,

F. W. DAVY,
Vice-Chairman.
